It is impossible to chronicle the efforts at expressing essence without pointing to diversity within the unity. Yet the belief in final unity belongs to any claims of finding an essence. Thus it was both a typical and a decisive moment when in the 5th century Vincent of Lérins, a Gallic theologian, provided a formula according to which Christianity expressed a faith that "has been believed everywhere, always, and by all" (*quod ubique, quod semper, quod ab omnibus creditum est*). Even if not all Christians could agree on all formulations, it was widely held that there was some fundamental "thing" that had thus been believed.

The formula of Vincent of Lérins

Medieval and Reformation views. For a thousand years, a period that began with what some historians called "Dark Ages" in the Christian West and that endured through both the Eastern and Western extensions of the Roman Empire, the essence of Christian faith was guarded differently than it had been in the first three centuries, before Christianity became official. By the 5th century, and with rare challenges until the 15th century, in the West the bishop of Rome, as pope and vicar of Christ, became the final custodian of the doctrinal essence of Christianity and could back support of his doctrine with the legal arm of the empire, the sword. In the Eastern churches no single pontiff ruled over the bishops, but they saw themselves just as surely and energetically in command of the doctrines that made up the essence of Christianity.

The Western drama was more fateful for Christianity in the modern world. The pope and the bishops of Roman Catholicism progressively saw themselves as determiners of the essence through doctrines and canons that enhanced the ancient grasp of faith. As they came to dominate in Europe, they allowed little room for those who did not agree with them. Jews were confined to ghettos, segregated and self-segregated enclaves where they did not and could not share the full prerogatives of Christendom, the "dominion" that now housed Christianity. When sects

Official doctrines as the essence

that were defined as heretical in their dissent—Waldenses, Albigenses, Cathari, and others—emerged to counter or contradict Roman Catholic concepts of Christian essence, they had to go into hiding or were pushed into enclaves beyond the enforcing reach of the custodians of official teaching. The essence of Christianity had become a set of doctrines and laws articulated and controlled by a hierarchy that saw those doctrines as a divine deposit of truth. Theologians might argue about the articulations with great subtlety and intensity, but in that millennium few would have chosen to engage in basic disagreement over the official teachings, all of which were seen to be corollaries of the basic faith in Jesus Christ as participating in the truth of God and providing the way of salvation.

When speaking of popes, bishops, councils, and theologians, it is necessary to make another distinction along with that which saw a narrowing of focus. Through these centuries there was also increasing differentiation between the official clergy and the wider body of believers. Most of what was debated centuries later about the essence of medieval Christianity came from the records of these authorities. As more is learned about the faith of the ordinary believers, it becomes more evident in the records of social history that people offered countless variations on the essence of the faith. Some historians point to survivals of European pagan customs and interpretations, which the later Protestant reformers saw to be threats to divine truth and the Jesus-centred way of salvation. Many people used the church's officially legitimated faith in the power of saints' relics to develop patterns of dealing with God that, according to the Reformers, detracted from the uniqueness of Jesus Christ as the only agent of salvation.

During this thousand years in both Western and Eastern Christianity, when the faith had a cultural monopoly, there was an outburst of creativity and a fashioning of a Christian culture that greatly enhanced and complicated any once-simple notions of an essence. Christianity was as much a cultural tradition as it was a faith tradition, an assertion that the leadership of the medieval church would not have regarded as diminishing or insulting.

As Christian culture grew ever more complex, however, there arose a constant stream of dissenters and individual reformers who tried to get back to what they thought was the original essence. Typical among these was St. Francis of Assisi, who in his personal style of devotion and simple way of life was often seen as capturing in his person and teachings more of the original essence of Jesus' truth and way of salvation than did the ordained authorities in the church and empires.

Out of this cluster of dissenters came late medieval reformers such as Jan Hus in Bohemia, John Wycliffe in England, and Girolamo Savonarola in Florence. For all their differences, they were united in their critique of what they thought complicated the essence of Christianity. On biblical prophetic grounds they sought simplicity in the cognitive, moral, and devotional life of Christianity. They may have disagreed over the essence of the faith, but they were united in what they thought were accretions that obscured the essence.

The Reformation as debates over essence

When the Protestant Reformation divided Western Christianity—as Eastern Christians, already separated since the 11th century, looked on—the 16th-century European world experienced a foretaste of the infinite Christian variety to come. The reforms that gave rise to the many Protestant bodies—Lutheran, Anglican, Presbyterian, Reformed, Anabaptist, Quaker, and others—were themselves debates over the essence of Christianity. Taken together, they made it increasingly difficult for any one to claim a monopoly on the custodianship of that essence. Each new sect offered a partial discernment of a different essence or way of speaking of it, even if the vast majority of Protestants agreed that the essence could be retrieved best, or, indeed uniquely, through recovery of the central message of the Holy Scriptures.

After the ferment of Reformation, most of the dissenting groups, as they established themselves in various nations, found it necessary to engage in their own narrowing of focus, rendering of precise doctrines, and understanding of divine truth and the way of salvation. Within a century theologians at many Protestant universities were adopting systems that paralleled the old scholasticisms against which some reformers had railed. Those who had once thought that definition of doctrine failed to capture the essence of Christianity were now defining their concept of the essence in doctrinal terms, but were doing so for Lutherans, Reformed, Presbyterians, and even for more radical dissenters and resistors of creeds, such as the Anabaptists.

The belief of Vincent of Lérins that there is a faith that has been held by everyone, always, and everywhere, lived on through the proliferation of Protestant denominations and Roman Catholic movements and, in sophisticated ways, has helped animate the modern ecumenical movement. Thus some have spoken of that movement as a reunion of churches, an idea that carries an implication that they had once been "one," and a further hint that that one included an essence on which people agreed. Reunion, then, would mean a stripping away of accretions, a reducing of the number of arguments, and a refocusing on essentials.

Modern views. The modern church and world brought new difficulties to the quest for defining an essence of Christianity. Both as a result of Renaissance humanism, which gloried in human achievement and encouraged human autonomy, and of Reformation ideas that believers were responsible in conscience and reason for their faith, an autonomy in expressing faith developed. Some spoke of Protestantism as being devoted to the right of private judgment. The danger, said Roman Catholic custodians of the essence, was that proud believers who did not submit to church authority would issue as many concepts of essence as there were believers to make the claims.

Effect of the Enlightenment

In the 18th century the Western philosophical movement called the Enlightenment further obscured searches for the essence of Christianity. The Enlightenment proclaimed optimistic views of human reach and perfectibility that challenged formerly essential Christian views of human limits. The deity became a benevolent if impersonal force, not an agent that arranged a way of salvation to people in need of rescue. The Enlightenment also clearly urged a view of human autonomy and of the use of reason in a search for truth. But this reason did not need to be responsive to supernatural revelation, as contained in the Old and New Testaments. Indeed, it called the integrity of those scriptures themselves into question through methods of historical and literary criticism. No longer should one rely on the word of priests who passed on notions of essential Christianity through systems of authority and force.

While many Westerners moved out of the orbit of faith as a result of the Enlightenment and the rise of criticism, many others—in Germany, France, England, Scotland, and, eventually, the Americas—chose to remain Christians, people of faith if now of faith differently expressed. Some, in groups called Arminian, professed such high views of human potential that their essence of Christianity prescribed no need for salvation. They thus constituted a real challenge to the profession of Vincent of Lérins. Another camp of Christians, the Unitarians, rejected the ideas of both a preexistent Logos made incarnate in Christ and a Jesus adopted into godhead. Jesus was seen as the great teacher or exemplar. They thus also tested the boundaries of essential teaching about a way of salvation. And at the heart of Deist Christianity was a view of God that remained "mono-" in that it was devoted to a single principle, but as "deist" instead of "theist" it departed from the ancient picture of a personal God engaged in human affairs. These were further blows to the integrity of Vincent of Lérins' concept and more reasons for the orthodox to use Vincent's concept to exclude Arminians, Unitarians, Deists, and other innovators from the circle of Christianity.

In the 19th century philosophical and historical criticism did inspire some Christians to renew the search for essences. For example, in the wake of the German Idealist philosopher G.W.F. Hegel, Hegelian scholars tried to rescue Christianity by viewing it as an unfolding of "absolute spirit." They followed Christian history through a constant dialectic, a series of forces and counterforces producing new syntheses. A problem with this Hegelian

approach arose as the historical Jesus came to be seen merely as one stage in the unfolding of absolute spirit; he was not a decisive agent of the way of salvation "once for all," as the biblical Letter to the Hebrews had claimed him to be. Soon biblical scholars such as David Friedrich Strauss were speaking of the historical Jesus as a myth of a certain set of people in one moment of the dialectical unfolding. The Christian faith itself began to dissolve, and many Hegelians began to reject the God of the Christian faith along with the historical Jesus.

Another group of 19th-century theologians took the opposite course. In the spirit of the 18th-century German philosopher Immanuel Kant, these neo-Kantians spoke not of the noumenal world, the unseen realm of essences beyond visible reality, but of the phenomenal realm, the world of history in which things happened. Theologians in this school engaged in a century-long "quest for the historical Jesus," in which they sought the simple essence of Christianity. Significantly, it was the greatest exemplar of this historical tradition, the German theologian Adolf von Harnack, who wrote the best-known modern book on the essence of Christianity, *Das Wesen des Christentums* (1900; *What Is Christianity?*).

The quest for the historical Jesus

The call had come to purge Christianity of what Harnack called traces of "acute Hellenization," the Greek ideas of essence, substance, and being that were introduced into the Christian tradition in the creed-making period. Instead, the focus was shifted to the Fatherhood of God and the announcement of the Kingdom, as the rabbi Jesus of Nazareth had proclaimed in the Gospels. While this approach did match the thirst for simplification in the minds of many of the Christian faithful, it also so diminished the concept of God that it often became a form of Christian humanism and was seen by the orthodox to be another departure from the essence of Christianity even as it claimed to find this in the historical Jesus. And scholars could not agree on the details of that historical Jesus after historical and literary critics had analyzed the Gospels.

Throughout the modern period some thinkers took another route toward expressing the essence of Christianity. Whether among German Pietists, the followers of John Wesley into Methodism, or any number of Roman Catholic or Protestant movements of devotion, there grew the notion that the theologians would never find the essence of Christianity. Instead, one would discern this essence in acts of piety, closeness to the fatherly heart of God as shown in the life of Jesus, or intimate communion with God on emotional or affective, and not cognitive, rational, or substantial (*i.e.*, doctrinal), grounds. These pietisms have been immensely satisfying to millions of modern believers, though they have often been handicapped in the intellectual arena when pressed for the definitions people need in a world of choice.

There have been some modern Christians who have shifted the topic from the essence of Christianity to its absoluteness among the religions. They have been moved by what the Germans called *Religionswissenschaft*, the study of world religions. In that school, the focus fell on the sacred, what the German theologian Rudolf Otto called "the idea of the Holy." There could be any number of expressions of this idea. On those terms, as the German scholar Ernst Troeltsch showed, it was more difficult to speak of the "absoluteness" of Christianity and its truth; one had to speak of it on comparative terms. Yet some early 20th-century comparativists, such as the Swedish Lutheran archbishop Nathan Söderblom, applied their understanding of the study of religion to help animate the movement for Christian reunion.

Ecumenism and essence

The modern ecumenical movement is made up of people who believe the church has different cultural expressions that must be honoured and differing confessional or doctrinal traditions designed to express the essential faith. These traditions demand criticism, comparison, and perhaps revision, with some possible blending toward greater consensus in the future. At the same time, years of serious ecumenical endeavour have shown that, among Christians of great intelligence and good will, elaborations of what constitutes the essence of Christianity are as confusing as they are inevitable and necessary.

In the Protestant and Orthodox side of the ecumenical movement, which took institutional form in the World Council of Churches in 1948, there were two main strands. Both of these included advocates of what were types of essential concepts. One set was devoted first to "Life and Work," a view that the essentials of Christianity could be best found and expressed when people followed the way or did the works of Christ, since this constituted his essence. The other set, concerned with "Faith and Order," stressed the need for comparative study of doctrine, with critical devotion to the search for what was central. By no means did these groups cling any longer to the notion that when they found unity they would have found a simple essence of Christianity. Yet they believed that they could find compatible elements that would help to sustain them on the never-ending search for what was central to the faith tradition.

Some modern scholars—for example, the British theologian John Hick—viewing the chaos of languages dealing with the essentials of the faith and the complex of historical arguments, pose the understanding of the essence in the future. They speak of "eschatological verification," referring to the end, the time beyond history, or the time of fulfillment. In that future, one might say, it will have become possible to assess the claims of faith. Theologians of these schools argue that such futuristic notions motivate Christians and the scholars among them to clarify their language, refine their historical understandings, and, some would say, focus their devotion and spirituality.

THE QUESTION OF CHRISTIAN IDENTITY

From these comments on the search for the essence of Christianity, the task of defining the core of the faith tradition, it can be seen that at all times the question of Christian identity is at stake. What the psychologist Erik Erikson said of the individual, that a sense of identity meant "the accrued confidence that one's ability to maintain inner sameness and continuity . . . is *matched* by the sameness and continuity of one's meaning for others," is thus translated to the concerns of the group. This means that Christians strive, in the midst of change, to have some "inner sameness and continuity" through the focus on Jesus Christ and the way of salvation.

At the same time, Christians posit that this identity will be discoverable by and useful to those who are not part of the tradition: secularists, Buddhists, Communists, or other people who parallel or rival Christian claims about truth and salvation.

The phenomenological approach to identity

On these terms, the writers of Christian history normally begin phenomenologically when discussing Christian identity; that is, they do not bring norms or standards by which they have determined the truth of this or that branch of Christianity or even of the faith tradition as a whole but begin by identifying everyone as Christian who call themselves Christian. Thus, from one point of view, the Church of Jesus Christ of Latter-day Saints, or the Mormons, is, as scholar Jan Shipps calls it, "a new religious tradition." The followers of the *Book of Mormon* incorporated the Old and New Testaments into their canon—just as the New Testament Christians incorporated the entire scripture of a previous tradition—and then supplied reinterpretations. As a new religious tradition, Mormonism would not be Christian. But because Mormons use Christian terminology and call themselves Christian, they might also, from some points of view and in some areas, belong to a discussion of Christianity. They may be perceived as departing from the essence of Christianity because other Christians regard their progressive doctrine of God as heretical. Yet Mormons in turn point to perfectionist views of humanity and progressive views of God among more conventionally accepted Christian groups. In areas where the Mormons want to be seen as "latter-day" restorers, basing their essential faith on scriptures not previously accessible to Christians, they would be ruled out of conventional Christian discussion and treatment. Yet they share much of Christian culture, focus their faith in Jesus, proclaim a way of salvation, and want to be included for other purposes, and thus fall into the context of a Christian identity at such times.

This phenomenological approach, one that accents historical and contemporary description and resists prescription, does not allow the historian to state the essence of Christianity as a simple guide for all discussion. It is necessary for the scholar to put his own truth claims in a kind of suspension and to record faithfully, sorting out large schools of coherence and pointing to major strains. It is not difficult to state that something was a majority view if the supporting data are present. For example, it is not difficult to say what Roman Catholics at particular times have regarded as the essence of Christianity or what the various Orthodox and Protestant confessions regard as the true way of salvation. Someone using the phenomenological method, however, would stand back and refuse to be the arbiter when these confessional traditions disagree over truth.

Vincent of Lérins, then, speaks more for the hunger of the Christian heart or the dream of Christian union than for the researcher, who finds it more difficult to see a moment when everyone agreed on everything everywhere. Yet provisionally it remains safe to say that Christian identity begins and ends with a reference to Jesus in relation to God's truth and a way of salvation. The rest is a corollary of this central claim, an infinite set of variations and elaborations that are of great importance to the separated Christians who hold to them in various times and places. (M.E.M.)

The history of Christianity

THE PRIMITIVE CHURCH

The relation of the early church to late Judaism. Christianity began as a movement within Judaism at a period when the Jews had long been under foreign influence and rule and had found in their religion (rather than in their politics or cultural achievements) the linchpin of their community. From Amos (8th century BC) onward the religion of Israel was marked by tension between the concept of monotheism, with its universal ideal of salvation (for all nations), and the notion of God's special choice of Israel. In the age after Alexander the Great (*i.e.*, the Hellenistic period, 3rd century BC–3rd century AD), the dispersion of the Jews throughout the Hellenistic kingdoms and the Roman Empire gave some impetus to the universalistic tendency. But the attempts of foreign rulers, especially the Syrian king Antiochus Epiphanes (in 168–165 BC), to impose Greek culture and religious syncretism in Palestine provoked zealous resistance on the part of many Jews. In Palestinian Judaism the predominant note was separation and exclusiveness. Jewish missionaries to other areas were strictly expected to impose the distinctive Jewish customs of circumcision, kosher food, and sabbaths and other festivals.

Universalistic and particularistic tendencies in Judaism

The relationship of the earliest Christian Church to Judaism turned principally on two questions: (1) the messianic role of Jesus of Nazareth and (2) the permanent validity of the Mosaic Law for all.

The Hebrew Scriptures viewed history as the stage of a providential drama eventually ending in a triumph of God over all present sources of frustration (*e.g.*, foreign domination or the sins of Israel). God's rule would be established by an anointed prince (the Messiah) of the line of David, king of Israel in the 10th century BC. The proper course of action leading to the consummation of the drama, however, was the subject of some disagreement. Among the diverse groups were the aristocratic and conservative Sadducees, who accepted only the five books of Moses (the Pentateuch), and the more popular and strict Pharisees. The Pharisees not only accepted biblical books outside the Pentateuch but also embraced doctrines—such

Jewish sectarianism

Spread of Christianity through the 11th century in Europe, North Africa, and the Middle East.

as those on resurrection and the existence of angels—of recent acceptance in Judaism, many of which were derived from apocalyptic expectations that the consummation of history would be heralded by God's intervention in the affairs of men in dramatic, cataclysmic terms. The Sanhedrin (central council) at Jerusalem was made up of both Pharisees and Sadducees. The Zealots were aggressive revolutionaries seeking independence from Rome. Other groups were the Herodians, supporters of the client kingdom of the Herods (a dynasty that supported Rome) and abhorrent to the Zealots, and the Essenes, a quasi-monastic dissident group, probably including the sect that preserved the Dead Sea Scrolls. This latter sect did not participate in the Temple worship at Jerusalem and observed another religious calendar; from their desert retreat they awaited divine intervention and searched prophetic writings for signs indicating the consummation.

What relation the followers of Jesus had to some of these groups is not clear. In the canonical Gospels (those accepted as authentic by the church) the main targets of criticism are the scribes and Pharisees, whose attachment to the tradition of Judaism is presented as legalistic and pettifogging. The Sadducees and Herodians likewise receive an unfriendly portrait. The Essenes are never mentioned. Simon, one of Jesus' 12 disciples, was or had once been a Zealot. Jesus probably stood close to the Pharisees.

Under the social and political conditions of the time, there could be no long future either for the Sadducees or for the Zealots—whose attempts to make apocalyptic dreams effective led to the destruction of Judaea after the two major Jewish revolts of 66–70 and 132–135 against the Romans. The choice for many Jews thus lay between the Pharisees and Christianity, the former dedicated to the meticulous preservation of the Mosaic Law and the latter to the universal propagation of the biblical faith as a religion for all mankind. Pharisaism as enshrined in the Mishna (Oral Law) and the Talmud (commentary on and addition to the Oral Law) became normative Judaism. By looking to the Gentile (non-Jewish) world and carefully dissociating itself from the Zealot revolutionaries, Christianity made possible its ideal of a world religion, at the price of sacrificing Jewish particularity and exclusiveness. The fact that Christianity has never succeeded in gaining the open allegiance of more than a minority of Jews is more a mystery to theologians than to historians.

The relation of the early church to the career and intentions of Jesus. The prime sources for knowledge of Jesus of Nazareth are the four canonical Gospels in the New Testament. Only a few probably authentic sayings of Jesus became preserved in oral tradition independent of these documents, though many sayings came to be put into his mouth. These noncanonical sayings are called agrapha (not in Scripture). The *Gospel of Thomas,* preserved in a Coptic Gnostic library found about 1945 in Egypt, contains several such sayings, besides some independent versions of canonical sayings. At certain points the Gospel tradition finds independent confirmation in the letters of the Apostle Paul. The allusions in non-Christian sources (the Jewish historian Josephus, the Roman historians Tacitus and Suetonius, and Talmudic texts) are almost negligible, except as refuting the unsubstantiated notion that Jesus might never have existed.

The Gospels as sources for knowledge about the early church

The first three Gospels, Matthew, Mark, and Luke, have a literary relation to one another and are hence called Synoptic. Mark was probably used by Matthew and Luke. John, differing in both pattern and content, appears richer in theological interpretation but in detail may preserve good historical information. As their titles imply, the Gospels are not detached reports but were written to serve religious needs; they resemble oil paintings rather than photographs. Legendary and apologetic (defensive) motifs, and the various preoccupations of the communities for which they were first produced, can readily be discerned as influences upon their narratives. Historical scholarship at present has insufficient tools to eliminate subjective judgments about the probability of many details (upon which there will always be disagreement), but the most persuasive scholarly consensus accepts the substance of the Gospel tradition as a veracious picture.

A prominent uncertainty is the matter of chronology. Matthew places the birth of Jesus at least two years before Herod the Great's death late in 5 BC or early in 4 BC. Luke connects Jesus' birth with a Roman census that, according to Josephus, occurred in AD 6–7 and caused a revolt against the governor Quirinius. Luke could be right about the census and wrong about the governor. The crucifixion under Pontius Pilate, prefect of Judaea (AD 26–36), was probably about the year 29–30, but again certainty is impossible.

Encounter with John the Baptist, the ascetic in the Judaean Desert who preached repentance and baptism in view of God's coming Kingdom, marked a decisive moment for Jesus' career. He recognized in John the forerunner of the kingdom that his own ministry was inaugurating. The first preaching of Jesus, in his home region of Galilee, took the form of vivid parables and was accompanied by miraculous healings. The Synoptic writers give a single climactic visit of Jesus to Jerusalem at the end of his career; but John may be right (implicitly supported by Luke 13:7) in representing his visits as more frequent and the period of ministry as lasting more than a single year. Jesus' attitude to the observance of the law generated conflict with the Pharisees, and, though the people protected him, he also aroused the fear and hostility of the ruling Jewish authorities. A triumphal entry to Jerusalem at Passover time (the period celebrating the Exodus of the Hebrews from Egypt in the 13th century BC) was the prelude to a final crisis. After a last supper with his disciples he was betrayed by one of them, Judas. Arrest and trial followed, first before the Sanhedrin and then before Pilate, who condemned him to crucifixion. The accusation before Pilate was sedition, in which the Evangelists saw a framed charge. It was universal Christian belief that three days after his death he was raised from the dead by divine power.

Jesus preached the imminent presence of God's Kingdom, in some texts as future consummation, in others as already present. The words and acts of Jesus were believed to be the inauguration of a process that was to culminate in a final triumph of God. His disciples recognized him as the Messiah, the Anointed One. He is not recorded to have used the word of himself. The titles Prophet and Rabbi also were applied to Jesus. His own enigmatic self-designation was "Son of man," sometimes in allusion to his suffering, sometimes to his future role as judge. This title is derived from the version of the Book of Daniel (7:13), where "one like a son of man," contrasted with beast figures, represents the humiliated people of God, ascending to be vindicated by the divine Judge. In the developed Gospel tradition the theme of the transcendent judge seems to be most prominent.

The Kingdom of God and apocalyptic hopes

Apocalyptic hope could easily merge into messianic zealotry. Moreover, Jesus' teaching was critical of the established order and encouraged the poor and oppressed, even though it contained an implicit rejection of revolution. Violence was viewed as incompatible with the ethic of the Kingdom of God. Whatever contacts there may have been with the Zealot movement (as the narrative of feeding 5,000 people in the desert may hint), the Gospels assume the widest distance between Jesus' understanding of his role and the Zealot revolution.

With this distance from revolutionary idealism goes a sombre estimate of human perfectibility. The gospel of repentance presupposes deep defilement in individuals and in society. The sufferings and pains of humanity under the power of evil spirits calls out for compassion and an urgent mission. All the acts of a disciple must express love and forgiveness, even to enemies, and also detachment from property and worldly wealth. To Jesus, the outcasts of society (prostitutes, the hated and oppressive tax agents, and others) were objects of special care, and censoriousness was no virtue. Though the state is regarded as a distant entity in certain respects, it yet has the right to require taxes and civic obligations: Caesar has rights that must be respected and are not incompatible with the fulfillment of God's demands.

Some of the futurist sayings, if taken by themselves, raise the question whether Jesus intended to found a church.

A negative answer emerges only if the authentic Jesus is assumed to have expected an immediate catastrophic intervention by God. There is no doubt that he gathered and intended to gather around him a community of followers. This community continued after his time, regarding itself as the specially called congregation of God's people, possessing as covenant signs the rites of baptism and Eucharist (Lord's Supper) with which Jesus was particularly associated—baptism because of his example, Eucharist because the Last Supper on the night before the crucifixion was marked as an anticipation of the messianic feast of the coming age.

Expansion of Christianity to include Gentiles

A closely related question is whether Jesus intended his gospel to be addressed to Jews only or if the Gentiles were also to be included. In the Gospels Gentiles appear as isolated exceptions, and the choice of 12 Apostles has an evident symbolic relation to the 12 tribes of Israel. The fact that the extension of Christian preaching to the Gentiles caused intense debate in the 40s of the 1st century is decisive proof that Jesus had given no unambiguous directive on the matter. Gospel sayings that make the Jews' refusal to recognize Jesus' authority as the ground for extending the Kingdom of God to the Gentiles must, therefore, have been cast by the early community.

The Gentile mission and St. Paul. Saul, or Paul (as he was later called), was a zealous Pharisee who persecuted the primitive church. Born at Tarsus (Asia Minor), he had come to Jerusalem as a student of the famous Rabbi Gamaliel and had harried a Christian group called by Luke the "Hellenists," who were led by Stephen (the first Christian martyr) and who regarded Jesus as a spiritual reformer sent to purge the corrupt worship of Jerusalem. While on a mission to persecute the followers of Jesus, Paul was suddenly converted to faith in Christ and, simultaneously, to a conviction that the Gospel must pass to the non-Jewish world under conditions that dispensed with exclusively and distinctively Jewish ceremonies. Paul was disapproved by Christian Jews who were of conservative opinions and remained throughout his career a controversial figure. He gained recognition for the converts of the Gentile mission by the Christian community in Jerusalem; but his work was considered an affront to Jewish traditionalism, and his program of being "all things to all men" led to bitter charges that he was an unprincipled trimmer. He saw clearly and correctly that the universal mission of the church to all humanity, implicit in the coming of the Messiah, or Christ, meant a radical break with rabbinical conservatism.

Gentile–Jewish debates within Christianity

Owing to the preservation of some weighty letters, Paul is the only vivid figure of the apostolic age (1st century AD). Like his elder contemporary Philo of Alexandria, also a Hellenized Jew of the dispersion, he interpreted the Old Testament allegorically (symbolically) and affirmed the primacy of spirit over letter in a manner that was in line with Jesus' freedom with regard to the sabbath. The crucifixion of Jesus he viewed as the supreme redemptive act and also as the means of expiation for the sin of mankind. Salvation is, in Paul's thought, therefore, not found by a conscientious moralism but rather is a gift of grace, a doctrine in which Paul was anticipated by Philo. But Paul linked this doctrine with his theme that the Gospel represents liberation from the Mosaic Law. The latter thesis created difficulties at Jerusalem, where the church was under the presidency of James, the brother of Jesus, and the circle of the intimate disciples of Jesus. James, martyred at Jerusalem in 62, was the primary authority for the Christian Jews, especially those made anxious by Paul; the canonical letter ascribed to James opposes the antinomian (anti-law) interpretations of the doctrine of justification by faith. A middle position seems to have been occupied by Peter. All the Gospels record a special commission of Jesus to Peter as the leader among the 12 Apostles. But Peter's biography can only be dimly constructed; he died in Rome (according to early tradition) in Nero's persecution (64) about the same time as Paul.

Apart from its success, the supremacy of the Gentile mission within the church was ensured by the effects on Jewish Christianity of the fall of Jerusalem (70) and Hadrian's exclusion of all Jews from the city (135). Jewish Christianity declined and became the faith of a very small group without links to either synagogue or Gentile church. Some bore the title Ebionites, "the poor" (compare Matthew 5:3). Among them some did not accept the tradition that Jesus was born of a virgin.

In the theology of Paul, the human achievement of Jesus was important because his obedient fidelity to his vocation gave moral and redemptive value to his self-sacrifice. A different emphasis appears in the Gospel According to John, written (according to 2nd-century tradition) at Ephesus. John's Gospel partly reflects local disputes, not only between the church and the Hellenized synagogue but also between orthodox Christianity and deviationist Gnostic groups in Asia Minor. John's special individuality lies in his view of the relation between the historical events of the tradition and the Christian community's present experience of redemption. The history is treated symbolically to provide a vehicle for faith. Because it is less attached to the contingent events of a particular man's life, John's conception of the preexistent Logos becoming incarnate (made flesh) in Jesus made intelligible to the Hellenistic world the universal significance of Jesus. In antiquity, divine presence had to be understood as either inspiration or incarnation. If the Synoptic Gospels suggest inspiration, the Gospel According to John chooses incarnation. The tension between these two types of Christology (doctrines of Christ) first became acute in the debate between the schools of Antioch and Alexandria in the late 4th century.

The contemporary social, religious, and intellectual world. Many Palestinian Jews appreciated the benefits of Roman rule in guaranteeing order and peace. The Roman government could tolerate regional and local religious groups and found it convenient to control Palestine through client kings like the Herods. The demand that divine honours be paid not only to the traditional Roman or similar gods but also to the emperors was not extended to Judaea except under the emperor Caligula (reigned 37–41). It was enough that the Jews dedicated temple sacrifices and synagogues in the emperor's honour. The privileges of Roman citizenship were possessed by some Jewish families, including that of the Apostle Paul.

Relationship of early Christianity to state and society

In his letter to the Romans, Paul affirmed the providential role of government in restraining evil. Christians did not need to be disaffected from the empire, though the deification of the emperor was offensive to them. Moreover, although as an agency of social welfare the church offered much to the downtrodden elements in society, the Christians did not at any stage represent a social and political threat. The ancient world did not possess a working-class movement in the modern sense, and Christianity did not create or foster one. After the example of their master, the Christians encouraged humility and patience before wicked men. Even the institution of slavery was not the subject of fundamental Christian criticism before the 4th century. The church, however, was not lost in pious mysticism. It provided for far more than the cultic (liturgical) needs of its members. Inheriting a Jewish moral ideal, its activities included food for the poor, orphans, and foundlings; care for prisoners; and a community funeral service.

The church inherited from Judaism also a strong sense of being holy, separate from idolatry and pagan eroticism. As polytheism with its attendant permissiveness permeated ancient society, a moral rigorism severely limited Christian participation in some trades and professions. At baptism a Christian was expected to renounce his occupation if that necessarily implicated him in public or private compromise with polytheism, superstition, dishonesty, or vice. About military service there was disagreement. The majority held that a soldier, if converted and baptized, was not required to leave the army, but there was hesitation about whether an already baptized Christian might properly enlist. Strict Christians also thought poorly of the teaching profession because it involved instructing the young in literature replete with pagan ideals and what was viewed as indecency. Acting and dancing were similarly suspect occupations. Any involvement in magic was completely forbidden.

The Christian ethic therefore demanded some detachment from society. In some cases this made for economic

difficulties. The structure of ancient society was dominated not by class but by the relationship of patron and client. A slave or freedman depended for his livelihood and prospects upon his patron. In antiquity a strong patron was indispensable if one was negotiating with police or tax authorities or lawcourts or if one had ambitions in the imperial service. The authority of the father of the family was considerable. Conversely, a man's power in society depended on the extent of his dependents and supporters. Often, Christianity penetrated the social strata first through women and children, especially in the upper classes. But once the householder was a Christian, his dependents tended to follow. The Christian community itself was close-knit. Third-century evidence portrays Christians banking their money with fellow believers; and widely separated groups helped one another with trade and mutual assistance.

Women in ancient society—Greek, Roman, or Jewish—had a domestic, not a public, role; feminine subordination was self-evident. To Paul, however, Christian faith transcends barriers to make all free and equal (Galatians 3:28). Of all ancient writers Paul was the most powerful spokesman for equality. Nevertheless, just as he refused to harbour a runaway slave, so he opposed any practice that would identify the church with social radicalism (a principal pagan charge against it). Paul did not avoid self-contradiction (1 Corinthians 11:5, 14:34–35). His opposition to a public liturgical role for women decided subsequent Catholic tradition in the East and West. Yet in the Greek churches (though not often in the Latin) women were ordained as deacons—in the 4th century by prayer and imposition of hands with the same rite as male deacons—and had a special responsibility at women's baptism. Widows and orphans were the neediest in antiquity, and the church provided them substantial relief. It also encouraged vows of virginity, and by AD 400 women from wealthy or politically powerful families acquired power as superiors of religious communities. It seemed natural to elect as abbess a woman whose family connections might bring benefactions.

Gentile religious environment

The religious environment of the Gentile mission was a tolerant, syncretistic blend of many cults and myths. Paganism was concerned with success; the gods gave victory in war, good harvests, success in love and marriage, and sons and daughters. Defeat, famine, civil disorder, and infertility were probable signs of cultic pollution and disfavour. People looked to religion for help in mastering the forces of nature rather than to achieve moral improvement. Individual gods cared either for specific human needs or for specific places and groups. The transcendent God of biblical religion was, therefore, very different from the numerous gods of limited power and local significance. In Asia Minor Paul and his coworker Barnabas were taken to be gods in mortal form because of their miracles. To offer sacrifice on an altar seemed a natural expression of gratitude to any dead, or even living, benefactor. Popular enthusiasm could bestow divine honours on such heroes as dead pugilists and athletes. In the Roman Empire it seemed natural to offer sacrifice and burn incense to the divine emperor as a symbol of loyalty, much like standing for a national anthem today.

Traditional Roman religion was a public cult, not private mysticism, and was upheld because it was the received way of keeping heaven friendly. To refuse participation appeared to be disloyal. The Jews could gain acceptance for their refusal by virtue of the undoubted fact that their monotheism was an ancestral national tradition. The Christians, however, did everything in their power to dissuade people from following the customs of their fathers, whether Gentiles or Jews, and thereby seemed to threaten the cohesion of society and the principle that each racial group was entitled to follow its national customs in religion.

If ancient religion was tolerant, the philosophical schools were seldom so. Platonists, Aristotelians, Stoics, Epicureans, and Skeptics tended to be very critical of one another. By the 1st century BC, an eclecticism emerged; and by the 2nd century AD, there developed a common stock of philosophy shared by most educated people and by some professional philosophers, which derived metaphysics involving theories on the nature of Being from Plato, ethics from the Stoics, and logic from Aristotle. This eclectic Platonism provided an important background and springboard for early Christian apologetics. Its main outlines appear already in Philo of Alexandria, whose thought influenced not only perhaps the writer of the anonymous letter to the Hebrews in the New Testament but also the great Christian thinkers Clement of Alexandria, Origen, and Ambrose of Milan. Because of this widespread philosophical tendency, the Christian could generally assume some belief in Providence and assent to high moral imperatives. Platonism in particular provided a metaphysical framework within which the Christians could interpret the entire pattern of creation, the Fall of humanity, the incarnation, redemption, the church, sacraments, and last things.

THE INTERNAL DEVELOPMENT OF THE EARLY CHRISTIAN CHURCH

The problem of jurisdictional authority. In the first Christian generation, authority in the church lay either in the kinsmen of Jesus or in those whom he had commissioned as Apostles and missionaries. The Jerusalem church under James, the brother of Jesus, was the mother church. Paul admitted that if they had refused to grant recognition to his Gentile converts he would have laboured in vain. If there was an attempt to establish a hereditary family overlordship in the church, it did not succeed. Among the Gentile congregations, the Apostles sent by Jesus enjoyed supreme authority. As long as the Apostles lived, there existed a living authoritative voice to which appeal could be made. But once they all had died, there was an acute question regarding the locus of authority. The earliest documents of the 3rd and 4th Christian generations are mainly concerned with this issue: what is the authority of the ministerial hierarchy? The apostolic congregations had normally been served by elders (Greek *presbyteroi,* "priests") or overseers (*episkopoi,* "bishops"), assisted by attendants (*diakonoi,* "deacons"). The clergy were responsible for preaching, for administering baptism and Eucharist, and for distributing aid to the poor. In each city the president or senior member of the college (assembly) of presbyters naturally had some special authority; he corresponded with other churches and, when they were ordaining a new president, would go as the representative of his own community and as a symbol of the catholicity—the universality and unity—of the church of Christ.

Bishops, presbyters, and deacons

Ignatius, bishop of Antioch early in the 2nd century, wrote seven letters on his way to martyrdom at Rome that indicate how critical the centrifugal forces in the church had made the problem of authority. The bishop, he insisted, is the unique focus of unity without whose authority there is no sacrament and no church. A few years earlier the letter of Bishop Clement of Rome (*c.* AD 95) to the church at Corinth based the hierarchy's authority on the concept of a historical succession of duly authorized teachers. Clement understood the clergy and laity to be essentially distinct orders within the one community, just as in the Old Testament there were high priests, priests, Levites (Temple functionaries), and laymen. The principles of Clement and Ignatius became important when the church was faced by people claiming recognition for their special charismatic (spiritual) gifts and especially by Gnostic heretics claiming to possess secret oral traditions whispered by Jesus to his disciples and not contained in publicly accessible records such as the Gospels.

The authority of the duly authorized hierarchy became enhanced by the outcome of another 2nd-century debate, about the possibility of absolution for sins committed after baptism. The *Shepherd of Hermas,* a book that enjoyed canonical status in some areas of the early church, enforced the point that excessive rigorism produces hypocrisies. By the 3rd century the old notion of the church as a society of holy people was being replaced by the conception that it was a school for frail sinners. In spite of protests, especially that of the schism led by the theologian and schismatic pope Novatian at Rome in 251, the final consensus held that the power to bind and loose (compare

Matthew 16:18–19), to excommunicate and absolve, was vested in bishops and presbyters by their ordination.

Early Christianity was predominantly urban; peasants on farms were deeply attached to old ways and followed the paganism favoured by most aristocratic landowners. By AD 400 some landowners had converted and built churches on their property, providing a "benefice" for the priest, who might often be one of the magnate's servants. In the East and in North Africa each township normally had its own bishop. In the Western provinces bishops were fewer and were responsible for larger areas, which, from the 4th century onward, were called by the secular term dioceses (administrative districts). In the 4th century pressure to bring Western custom into line with Eastern and to multiply bishops was resisted on the ground that it would diminish the bishops' social status. By the end of the 3rd century the bishop of the provincial capital was acquiring authority over his colleagues: the metropolitan (from the 4th century on, often entitled archbishop) was chief consecrator of his episcopal colleagues. The bishops of Rome, Alexandria, and Antioch in the 3rd century were accorded some authority beyond their own provinces. Along with Jerusalem and Constantinople (founded in 330), these three sees (seats of episcopal authority) became, for the Greeks, the five patriarchates. The title *papa* ("father") was for 600 years an affectionate term applied to any bishop to whom one's relation was intimate; it began to be specially used of bishops of Rome from the 6th century and by the 9th century was almost exclusively applied to them.

Expansion of administrative authority

From the beginning, the Christians in Rome were aware of special responsibilities for them to lead the church. About AD 165, memorials were erected at Rome to the Apostles Peter and Paul, to Peter in a necropolis on the Vatican Hill, and to Paul on the road to Ostia. The construction reflects a sense of being guardians of an apostolic tradition, a self-consciousness expressed in another form when, about 190, Bishop Victor of Rome threatened with excommunication Christians in Asia Minor who, following immemorial custom, observed Easter on the day of the Jewish Passover rather than (as at Rome) on the Sunday after the first full moon after the spring equinox. Stephen of Rome (256) is the first known pope to base claims to authority on Jesus' commission to Peter (Matthew 16:18–19).

Bishops were elected by their congregations—*i.e.*, by the clergy and laity assembled together. But the consent of the laity decreased in importance as recognition by other churches increased. The metropolitan and other provincial bishops soon became just as important as the congregation as a whole; and, though they could never successfully impose a man on a solidly hostile community, they could often prevent the appointment falling under the control of one powerful lay family or faction. From the 4th century on, the emperors occasionally intervened to fill important sees, but such occurrences were not a regular phenomenon (until the 6th century in Merovingian Gaul).

The problem of scriptural authority. After the initial problems regarding the continuity and authority of the hierarchy, the greatest guarantee of true continuity and authenticity was found in the Scriptures. Christians inherited (without debate at first) the Hebrew Bible as the Word of God to the people of God at a now superseded stage of their pilgrimage through history. If St. Paul's Gentile mission was valid, then the Old Testament Law was viewed as no longer God's final word to his people. Thus, the Hebrew Bible began to be called the *old* covenant. There was some hesitation in the church about the exact books included. The Greek version of the Old Testament (Septuagint) included books (such as the Wisdom of Solomon, Ecclesiasticus, and others) that were not accepted in the Hebrew canon. Most, but not all, Gentile Christian communities accepted the Septuagintal canon. The 3rd-century Alexandrian theologian Origen and especially the Latin biblical scholar Jerome (4th–5th century) believed it imprudent to base theological affirmations on books enjoying less than universal recognition. The fact that in many English Bibles the parts of the Old Testament accepted in the Septuagint but not in the Hebrew canon are often printed separately under the (misleading) title Apocrypha is a tribute to these ancient hesitations.

The emergence of a canon of Christian Scripture

The growth of the New Testament is more complex and controversial. First-century Christians used oral tradition more than writing to pass on the story of Jesus' acts and words, often told in the context of preaching and teaching. No one thought they needed to be in writing to bear authority. Mark first conceived the plan of composing a connected narrative. Nevertheless, even after the Gospels were in common circulation, oral tradition was still current and could even be preferred. A carefully copied document, however, provided greater security against contamination of the tradition. The Synoptic Gospels seem to have been used by the Apologist Justin Martyr at Rome about AD 150 in the form of an early harmony (or synthesis of the Gospels); to this, Justin's Syrian pupil Tatian added the Gospel According to John to make his *Diatessaron* (according to the four), a harmony of all four Gospels so successful that in Mesopotamia (Tatian's homeland) it virtually ousted the separate Gospels for 250 years.

On a second grade of authority stood the apostolic letters, especially those of Paul. The main body of his correspondence was circulating as a corpus (body of writings) well before AD 90.

Significance of Marcion

Paul's antitheses of law and grace, justice and goodness, and the letter and the spirit were extended further than Paul intended by the radical semi-Gnostic heretic Marcion of Pontus (*c.* 140–150), who taught that the Old Testament came from the inferior vengeful Jewish God of justice and that the New Testament told of the kindly universal Father. As the current texts of Gospels and letters presupposed some divine revelation through the Old Testament, Marcion concluded that they had been corrupted and interpolated by Judaizers. Marcion therefore established a fixed canon of an edited version of Luke's Gospel and some of the Pauline Letters (expurgated), and no Old Testament at all.

The orthodox reaction (by such theologians as Justin, Irenaeus, and Tertullian in the 2nd century) was to insist on the Gospel as the fulfillment of prophecy and on creation as the ground of redemption. Reasons were found for accepting the four already current Gospels, the full corpus of Pauline Letters, Acts, John's Revelation (Apocalypse), and some of the Catholic Letters (these last—I, II, and III John, James, and Jude—were the subject of hesitations). On the authorship of the Letter to the Hebrews there were doubts: Rome rejected it as non-Pauline and Alexandria accepted it as Pauline. The list once established was a criterion (the meaning of "canon") for the authentic Gospel of the new covenant and soon (by transference from the old) became entitled the New Testament. (The Greek word *diathēkē* means both covenant and testament.) The formation of the canon meant that special revelation ended with the death of the Apostles and that no authority could be attached to the apocryphal gospels, acts, and apocalypses proliferating in the 2nd century.

The problem of theological authority. Third, a check was found in the creed. At baptism, after renouncing "the devil and his pomps," initiates declared their faith in response to three questions of the form:

> Do you believe in God the Father almighty? Do you believe in Jesus Christ his Son our Lord. . . ? Do you believe in the Holy Spirit in the church and in the Resurrection?

In time, these interrogations became the basis of declaratory creeds, adapted for use by the clergy who felt themselves required to reassure colleagues who were not especially confident of their orthodoxy. The so-called Apostles' Creed is a direct descendant of the baptismal creed used at Rome by AD 200. Each church (or region) might have its own variant form, but all had the threefold structure.

The internal coherence given by creed, canon, and hierarchy was necessary both in the defense of authentic Christianity against Gnostic theosophical speculations and also in confronting pagan society. The strong coherence of the scattered congregations was remarkable to pagan observers.

Gnosticism and Montanism

Early heretical movements. Gnosticism was the greatest threat to Christianity before 150 and somewhat thereafter. Gnostics taught that there is total opposition between this evil world and God. Redemption was viewed as libera-

tion from the chaos of a creation derived from either incompetent or malevolent powers, a world in which the elect are alien prisoners. The method of salvation was to discover the Kingdom of God within one's elect soul and to learn how to pass the hostile powers barring the soul's ascent to bliss. Gnosticism destroyed the notion of a historical disclosure of God. Its pessimism and dualism (in which matter was viewed as evil and spirit good) had disturbing moral consequences, involving both asceticism and libertinism. Its claims to a totally transcendent revelation were antirational, allowed for no natural goodness in the created order, and eliminated individual responsibility. Both the orthodox theologians and the pagan 3rd-century philosopher Plotinus dismissed Gnosticism as a pretentious but dangerous mumbo jumbo for misleading the half-educated.

The orthodox stressed the need to adhere to tradition, which was attested by the churches of apostolic foundation. A more hazardous reply was to appeal to ecstatic prophecy. About AD 172 a quasi-pentecostal movement in Phrygia was led by Montanus with two prophetesses, reasserting the imminence of the end of the world. He taught that there was an age of the Father (Old Testament), an age of the Son (New Testament), and an age of the Spirit (heralded by the prophet Montanus). Montanism won its chief convert in the Latin theologian Tertullian of Carthage. Its claim to supplement the New Testament was generally rejected.

RELATIONS BETWEEN CHRISTIANITY AND THE ROMAN GOVERNMENT AND THE HELLENISTIC CULTURE

Church–state relations. The Christians were not respectful toward ancestral pagan customs. Their preaching of a new king sounded like revolution. The opposition of the Jews to them led to breaches of the peace. Thus the Christians could very well be unpopular, and they often were. Paul's success at Ephesus provoked a riot to defend the cult of the goddess Artemis. In AD 64 a fire destroyed much of Rome; the emperor Nero killed a "vast multitude" of Christians as scapegoats. For the first time, Rome was conscious that Christians were distinct from Jews. But there probably was no formal senatorial enactment proscribing Christianity at this time. Nero's persecution was local and short. Soon thereafter, however, the profession of Christianity was defined as a capital crime, though of a special kind because one gained pardon by apostasy (rejection of a faith once confessed) demonstrated by offering sacrifice to the pagan gods or the emperor. Popular gossip soon accused the Christians of secret vices, such as eating murdered infants (due to the secrecy surrounding the Lord's Supper and the use of the words body and blood) and sexual promiscuity (due to the practice of Christians calling each other "brother" or "sister" while living as husband and wife). The governor of Bithynia in AD 111, the younger Pliny, told the emperor Trajan that to his surprise he discovered the Christians to be guilty of no vice, only of obstinacy and superstition. Nevertheless, he executed without a qualm those who refused to apostatize.

Causes of persecutions

Early persecutions were sporadic, caused by local conditions and depending on the attitude of the governor. The fundamental cause of persecution was that the Christians conscientiously rejected the gods whose favour was believed to have brought success to the empire. But distrust was increased by Christian detachment and reluctance to serve in the imperial service and in the army. At any time in the 2nd or 3rd centuries, Christians could find themselves the object of unpleasant attention. A pogrom could be precipitated by a bad harvest, a barbarian attack, or a public festival of the emperor cult. Yet, long periods of peace occurred. In 248–250, when Germanic tribes threatened the empire, popular hostility culminated in the persecution under the emperor Decius (reigned 249–251): by edict all citizens were required to offer sacrifice and to obtain from commissioners a certificate witnessing to the act. Many of these certificates have survived. The requirement created an issue of conscience, especially because certificates could be bought by bribes. Under renewed attack (257–259), the great bishop-theologian Cyprian of Carthage was martyred. The persecuting emperor Valerian, however, became a Persian prisoner of war, and his son Gallienus issued an edict of toleration restoring confiscated churches and cemeteries. The church prospered from 261 to 303, but the empire suffered external attack, internal sedition, and rampant inflation. In February 303 the worst of all persecutions erupted under the co-emperors Diocletian and Galerius. The persecutions ended and peace was reached with the Edict of Milan, a manifesto of toleration issued in 313 by the joint emperors Licinius and his Christian colleague Constantine. Disagreements about the point at which the state must be resisted led to long lasting schisms in Egypt (Melitianism) and North Africa (Donatism).

Christianity and classical culture. St. Paul could quote such pagan poets as Aratus, Menander, and Epimenides. Clement of Rome cited the dramatists Sophocles and Euripides. Educated Christians shared this literary tradition with educated pagans. The defenders of Christianity against pagan attack (especially Justin Martyr and Clement of Alexandria in the 2nd century) welcomed classical philosophy and literature; they wished only to reject all polytheistic myth and cult and all metaphysical and ethical doctrines irreconcilable with Christian belief (*e.g.*, Stoic materialism and Platonic doctrines of the transmigration of souls and the eternity of the world). Clement of Alexandria, second known head of the catechetical school at Alexandria, possessed a wide erudition in the main classics and knew the works of Plato and Homer intimately. His successor at Alexandria, Origen, showed less interest in literary and aesthetic matters but was a greater scholar and thinker; he first applied the methods of Alexandrian philology to the text of the Bible.

Nevertheless, both pagans and Christians instinctively assumed the unity of ancient culture and pagan religion; it was hard for Christians to attack paganism without seeming negative toward the totality of classical culture as well as disaffected toward the imperial government. The urgent eschatological hope of the earliest church had built into its ethic a deep detachment from this world's goods, however beautiful they might be esteemed. This detachment emerged in one form in the evaluation of celibacy as superior to marriage, in another in a conscious renunciation of pretensions to high culture (in the manner of the not always popular or socially accepted pre-Christian Cynic philosophers with whom pagans found it natural to compare the Christians). The passionate urgency of the Christian mission admitted no distraction, an attitude that stamped any serious interest in science, history, or belles lettres with the stigma of worldliness.

Attitude of Christians toward other religions

The attitude of the Christians toward other religions (except Judaism) was generally very negative. All forms of paganism—the Oriental mystery (salvational) religions of Isis, Attis, Adonis, and Mithra as well as the ancient cults of classical Greece and Rome—were regarded as the cults of evil spirits. Like the Jews, the Christians (unless Gnostic) were opposed to syncretism. With the exception of the notion of baptism as a rebirth, Christians generally and significantly avoided the characteristic vocabularies of the mystery religions. The mysteries of Isis, Attis, Adonis, and (to some extent, perhaps) Mithra were basically fertility rites to ensure good crops. They answered to needs different from those addressed by the Christian gospel. A Mithraic rite with bread and water was noted by Justin Martyr as a counterpart of the bread and wine of the Christian Eucharist. The spring rites mourning Attis' death and then celebrating his revival at the festival known as the Hilaria offered a parallel to the ceremonies of Holy Week and Easter as developed in the 4th century. The point where parallel can be treated as influence, however, is a delicate matter to determine. Between Christianity and the pagan cults the most prominent difference consisted in the syncretistic tolerance of the latter; initiation into the mysteries of Isis did not mean renouncing allegiance to Apollo or Attis, whereas the Christian baptism required exclusive devotion.

Many converts naturally brought old attitudes with them into the church. Amulets and peasant superstitions were long the object of critical attention by the clergy. The Christians tried to provide counter-attractions by placing

Christian festivals on the same days of the year as pagan feasts. Solar monotheism was popular in late 3rd-century paganism, and soon the Western churches were keeping the winter solstice (December 25) as Christ's Nativity—the East kept January 6. Midsummer Day was replaced by the feast of John the Baptist. The church fought hard against the heathen celebration of January 1, but with little success. Only Easter (celebrating Christ's Resurrection) and Pentecost (celebrating the advent of the Holy Spirit) were feasts owing nothing to Gentile analogies for their origin; they both were derived from Jewish feasts. From the 5th century AD on, great pagan temples, such as the Parthenon in Athens, were gradually transformed into churches.

Apologetics. The Christian Apologists of the 2nd century sought to drive a wedge between the pagan religion that they abhorred and the Greek philosophy that, with occasional reservations, they welcomed. Second-century Platonism found it easy to think of Mind (nous) or Reason (Logos) as divine power immanent within the world. Philo of Alexandria had spoken of the Logos as mediating between the transcendent God and this created order. The Logos theology was developed by Justin Martyr both to make a positive evaluation of the best elements in the Greek philosophical tradition and to make the incarnation of Christ intelligible to the Greek mind. But the Apologists upset some of their fellow Christians by talking of the divine Logos as virtually a second God beside the Father and thus compromising the monotheism that the orthodox were defending against Gnostic dualism. The critics of the Logos theology, labeled Monarchians, affirmed that Father, Son, and Spirit were one God; the three names were epithets, not substantives. In the 3rd century a Roman presbyter, Sabellius, was excommunicated for this opinion, and the defenders of the Logos theology ousted the opponents of speculative apologetics. Clement of Alexandria and Origen provided the Greek churches with a Platonizing theology that was strongly opposed to the Monarchian position.

THE EARLY LITURGY, THE CALENDAR, AND THE ARTS

Christian worship and practices

Paul's letters mention worship on the first day of the week. In John's Apocalypse, Sunday is called "the Lord's day." The weekly commemoration of the Resurrection replaced for Christians the synagogue meetings on Saturdays; the practice of circumcision was dropped, and initiation was by baptism; continuing membership of the church was signified by weekly participation in the Eucharist. Baptism in water in the name of Father, Son, and Holy Spirit was preceded by instruction (catechesis) and fasting. Persons about to be baptized renounced evil and, as they made the declaration of faith, were dipped in water; they then received by anointing and by the laying on of hands (confirmation) the gift of the Holy Spirit and incorporation within the body of Christ, thus concluding the entire rite. Only the baptized were allowed to be admitted to the Eucharist, when the words of Jesus at the Last Supper were recalled; the Holy Spirit was invoked upon the people of God making the offering, and the consecrated bread and wine were distributed to the faithful. Accounts of these rites are given in the works of Justin (*c.* 150) and especially in the *Apostolic Tradition* of Hippolytus of Rome (*c.* 220).

To fall into a grave fault after baptism entailed exclusion. Excommunicated persons would continue to attend for the first part of the service, which included psalms, readings, and a sermon. Montanists, such as Tertullian, and the Roman schismatic Novatian denied the church's power to grant absolution. Even Cyprian of Carthage found Novatian easier to criticize for schism than for rigorism. But in the 3rd century a system of public penance emerged; it was allowed once a lifetime under condition of ascetic discipline. Penitents were restored to fellowship with church members by the laying on of hands. In time, less arduous and less public severities came to be required.

Before the 4th century, worship was in private houses. A house church of AD 232 has been excavated at Doura-Europus on the Euphrates. Whereas pagan temples were intended as the residence of the god, churches were designed for the community. The rectangular basilica with an apse (semicircular projection to house the altar) was found especially suitable. The Doura-Europus church has Gospel scenes on the walls. But many Old Testament heroes also appear in the earliest Christian art; Jewish models probably were followed. The artists also adapted conventional pagan forms (good shepherd; praying persons with hands uplifted). Fishing scenes, doves, and lyres also were popular. In themselves neutral, they carried special meaning to the Christians.

Vincenzo Biolghini

The Good Shepherd (centre), Orantes with uplifted hands, and (in the four quarters) the story of Jonah with figures derived from Greek mythological prototypes. Ceiling painting in the catacombs of SS. Peter and Marcellinus, Rome, 3rd century.

The words of several pre-Constantinian hymns survive (*e.g.*, "Shepherd of tender youth," by Clement of Alexandria), but only one with musical notation (Oxyrhynchus papyrus 1786 of the 3rd century).

The earliest Christians wrote to convert or to edify, not to please. Their literature was not produced with aesthetic intentions. Nevertheless, the pulpit offered scope for oratory (as in Melito of Sardis' *Homily on the Pascha, c.* 170). Desire for romance and adventure was satisfied by apocryphal Acts of the Apostles, recounting their travels, with continence replacing love. Justin and Irenaeus did not write for high style but simply to convey information. Apologists hoping for well-educated readers, however, could not be indifferent to literary tastes. By AD 200 the most graceful living writer of Greek literature was Clement of Alexandria, the liveliest writer of Latin, Tertullian. Wholly different in temperament (Clement urbane and allusive, Tertullian vigorous and vulgar), both men wrote distinguished prose with regard to form and rhetorical convention.

By the 3rd century the Bible needed explanation. Origen of Alexandria set out to provide commentaries and undertook for the Old Testament a collation of the various Greek versions with the original Hebrew. Many of his sermons and commentaries were translated into Latin by Tyrannius Rufinus and Jerome (*c.* 385–400); their learning and passionate mystical aspiration shaped Western medieval exegesis (critical interpretive methods).

THE ALLIANCE BETWEEN CHURCH AND EMPIRE

Constantine the Great, declared emperor at York, Britain (306), was converted to Christianity (312), became sole emperor (324), virtually presided over the ecumenical Council of Nicaea (325), founded the city of Constantinople (330), and died in 337. In the 4th century he was regarded as the great revolutionary, especially in religion. He did not make Christianity the religion of the empire, but his foundation of Constantinople (conceived to be

Constantinople as the new Rome

the new Rome) as a Christian city profoundly affected the future political and ecclesiastical structure. Relations with old Rome were not to be cordial either in matters of church or state. Despite massive legislation (some attempting to express Christian ideals—*e.g.,* making Sunday a rest day), he failed to check the drastic inflation that began about 250 and that soon created deep unrest and weakened the empire before the barbarian invasions of the 5th century.

Constantine brought the church out of its withdrawal from the world to accept social responsibility and helped pagan society to be won for the church. On both sides, the alliance of the church and emperor evoked opposition, which among the Christians emerged in the monks' retirement to the desert. Except for the brief reign of Julian the Apostate (361–363), pagans relapsed into passive resistance. The quietly mounting pressure against paganism in the 4th century culminated in the decrees of Emperor Theodosius I (reigned 379–395), who made orthodox Christianity an ingredient of good citizenship. Under Theodosius many pagan temples were closed or even destroyed (*e.g.,* the Alexandrian Serapeum). But until the time of Justinian (reigned 527–565), pagans were largely unmolested by the government. Heretics were more harshly treated. Ecclesiastical censures (from 314 on) were often enforced by the civil penalty of exile. One heretic, Priscillian, was even executed for witchcraft (385), but in the face of vehement church protests.

The link between church and state was expressed in the civil dignity and insignia granted to bishops, who also began to be entrusted with ambassadorial roles. By 400 the patriarch of Constantinople (to his avowed embarrassment) enjoyed precedence at court before all civil officials. In the writings of Ambrose (bishop of Milan, 374–397), "Roman" and "Christian" are almost synonyms. The Arian controversy (involving a denial of the divinity of Jesus) developed into a conflict between church and state when the emperor Constantius was supporting Arianism; and Ambrose enforced upon Theodosius submission to the church as its son, not its master. With an orthodox emperor, however, most Christians thought of church and empire as virtually coterminous.

Relationships with the barbarians

The church was significantly slow to undertake missionary work beyond the frontiers of the empire. The Goth Ulfilas converted the Goths to Arianism (*c.* 340–350) and translated the Bible, omitting, as unsuitable, warlike passages of the Old Testament. The Goths passed their Arian faith on to other Germanic tribes, such as the Vandals. (The first tribe to become Catholic was the Franks, in about 506, soon to be followed by the Visigoths.) In the 5th century the Western provinces were overrun by the barbarian Goths, Vandals, and Huns. The Roman Army had long drawn its recruits from the barbarian tribesmen and was itself now under barbarian generals. Theodosius I's will placed his two sons under the guardianship of the barbarian general Stilicho, who effectively ruled until they were able to assume responsibility. In the 5th century, Western emperors exercised less power than generals, and the imperial succession ended when a German leader, Odoacer, decided (476) to rule without an emperor. The end of the line of Western emperors made little difference to either church or state. In the West the position of the papacy was enhanced by the decline of state power, and this prepared the way for the popes' temporal sovereignty over parts of Italy (which they retained from the 7th to the 19th century).

The barbarian invasions destroyed Western schools. Specifically church schools were first created in late antiquity. The main preservers and transmitters of ancient culture, however, were the monks. Monasticism had begun in the Egyptian desert in the 4th century with Anthony the Hermit and with Pachomius, the first organizer of an ascetic community under a rule of obedience. Basil, bishop of Caesarea Cappadociae (370–379), rejected the hermit ideal and insisted on communities with a rule safeguarding the bishop's authority and with concrete acts of service to perform (*e.g.,* hospital work and teaching). The monastic ideal quickly spread to the West but owed its decisive shape there to John Cassian of Marseille (*c.* 360–435) and Benedict of Nursia (*c.* 480–*c.* 547). The manual work of monks often was the copying of manuscripts. Benedict's contemporary Cassiodorus (*c.* 490–*c.* 585) had the works of classical authors copied (*e.g.,* Cicero and Quintilian) as well as Bibles and the works of the early Church Fathers.

THEOLOGICAL CONTROVERSIES OF THE 4TH AND 5TH CENTURIES

Western controversies. Until about 250 most Western Christian leaders spoke Greek, not Latin (*e.g.,* Irenaeus and Hippolytus). The main Latin theology came not from Rome but from North Africa (*e.g.,* Tertullian and Cyprian). Tertullian wrote *Against Praxeas,* in which he discussed the doctrines of the Trinity and the Person of Christ. But in 251 Novatian's schism at Rome diverted interest away from speculative theology to juridical questions about the membership of the church and the validity of sacraments. These questions led to a schism between Rome and the churches of North Africa, which centred on a controversy at Carthage over ideas espoused by Donatus (313). The Donatist issue, which raised questions about the validity of the sacraments, involved the theology of Cyprian (bishop of Carthage, 248–258) and dominated all North African church life. Cyprian and the Donatists said that the validity of the sacraments depended on the worthiness of the minister; Rome and North African Christians in communion with Rome said that it did not because the sacraments received their validity from Christ, not man. Thus, even if inefficacious, baptism could be validly administered by a schismatic. Much of the great theologian Augustine's energies as bishop of Hippo (from 396 to 430) went into trying to settle the Donatist issue, in which he finally despaired of rational argument and reluctantly came to justify the use of limited coercion.

Donatism, Pelagianism, Arianism, and Monophysitism

The other major controversy of the Western Church was a more confused issue, namely, whether faith is caused by divine grace or human freedom. Augustine ascribed all credit to God. The British monk Pelagius protested that Augustine was destroying responsibility and denying the capacity of man to do what God commands. Both men applied inappropriate, impersonal categories of thought to the problem; and though Pelagianism was condemned, several of the extreme positions of Augustine (especially on predestination and the transmission of original sin) failed to receive the church's cordial endorsement.

Eastern controversies. In the Greek East, the 4th century was dominated by controversy about the propositions of Arius, an Alexandrian presbyter (*c.* 250–336), that the incarnate Lord who was born, wept, suffered, and died could not be one with the transcendent first cause of creation who is beyond all suffering. The Council of Nicaea (325) condemned Arianism and affirmed the Son of God to be identical in essence with the Father. As this formula included no safeguard against Monarchianism, a long controversy followed, especially after Constantine's death (337). Athanasius, bishop of Alexandria (reigned 328–373), fought zealously against Arianism in the East and owed much to Rome's support, which made the controversy add to the tensions between East and West. These tensions survived the settlement of the Arian dispute when the Council of Constantinople (381) eliminated Arianism in the East but also asserted Constantinople to be the second see of Christendom, as the new Rome. This assertion was unwelcome to Alexandria, traditionally second city of the empire, and to Rome because it implied that the dignity of a bishop depended on the secular standing of his city. Rivalry between Alexandria and Constantinople led to the fall of John Chrysostom, patriarch of Constantinople (reigned 398–404), when he appeared to support Egyptian monks who admired the controversial theology of Origen. It became a major feature of the emerging Christological debate (the controversy over the nature of Christ).

The Christological controversy stemmed from the rival doctrines of Apollinaris of Laodicea (flourished 360–380) and Theodore of Mopsuestia (*c.* 350–428), representatives of the rival schools of Alexandria and Antioch, respectively. At the Council of Ephesus (431), led by Cyril, patriarch of Alexandria (reigned 412–444), an extreme Antiochene Christology—taught by Nestorius, patriarch

of Constantinople—was condemned for saying that the man Jesus is an independent person beside the divine Word and that therefore Mary, the mother of Jesus, may not properly be called mother of God (Greek *theotokos*, or "God-bearer"). Cyril's formula was "one nature of the Word incarnate." A reaction led by Pope Leo I (reigned 440–461) against this one-nature (Monophysite) doctrine culminated in the Council of Chalcedon (451), which affirmed Christ to be two natures in one person (hypostasis). Thus, the Council of Chalcedon alienated Monophysite believers in Egypt and Syria.

During the next 250 years the Byzantine emperors and patriarchs desperately sought to reconcile the Monophysites. Three successive attempts failed: (1) under the emperor Zeno (482) the *Henotikon* (union formula) offended Rome by suggesting that Monophysite criticism of Chalcedon might be justified; (2) under the emperor Justinian the Chalcedonian definition was glossed by condemning the "Three Chapters," which includes the writings of Theodore of Mopsuestia, Theodoret, and Ibas, all strong critics of Cyril of Alexandria's theology and of Monophysitism; the Syrian Monophysite Jacob Baradaeus reacted to this by creating a rival Monophysite episcopate and permanent schism; (3) under the emperor Heraclius (reigned 610–641) the Chalcedonians invited the Monophysites to reunite under the formula that Christ had two natures but only one will (Monothelitism), but this reconciled almost no Monophysites and created divisions among the Chalcedonians themselves. Chalcedon's "two natures" continues to be rejected by the Armenian Apostolic Church, Coptic Orthodox Church, Ethiopian Orthodox Church, and Syrian Orthodox Patriarchate of Antioch (Syrian Jacobites).

POPULAR CHRISTIANITY IN THE LATE EMPIRE

The continuity of pre-Christian antiquity and Christian society is nowhere more apparent than in popular religious practice. Pagans were normally devoted to local shrines of particular gods. The church tried to meet this psychological need by establishing shrines of martyrs. The martyr cult, a matter of private devotion from 150 until 250, became so popular after the Decian persecution that official control was required. Invocation of Mary as "mother of God" is first attested in a 3rd-century papyrus. At Rome the shrines of Peter and Paul, where Constantine built basilicas, attracted many pilgrims. The holy places in Jerusalem and Bethlehem, however, were preeminent.

Emergence of the cult of martyrs and saints

Preachers might warn that pilgrimage did not necessarily bring one nearer to God and that one must not worship the martyrs being venerated, but at the popular level such exhortations seemed sophisticated. The bones of martyrs and other holy persons were so treasured that a traffic in bogus relics was created. By 400, particular saints were being invoked for particular needs (one for health, another for fertility, travel, prediction, or the detection of perjury). When the barbarian leader Alaric's Goths sacked Rome (410), citizens asked why Peter and Paul had failed to protect their city.

Pagan critics said that the old gods, true givers of success and miracle, were offended by neglect. To meet such criticisms the churches found it necessary to provide similar assurances of success, miraculous cures, and patron saints. By the 6th century, wonder-working shrines, cloths that had touched holy relics, and pictures (icons) were invested with numinous (spiritual) power. Because of the antielitist ideology of the Christian tradition, even highly educated figures such as Augustine and Pope Gregory I the Great (reigned 590–604) were sympathetic to this popular movement. It became a means of winning the barbarian tribesmen.

LITURGY AND THE ARTS AFTER CONSTANTINE

Development of new forms of worship

The veneration of martyrs and the growth of pilgrimages stimulated liturgical elaboration. Great centres (Jerusalem and Rome, in particular) became models for others, which encouraged regional standardization and cross-fertilization. Though the pattern of the eucharistic liturgy was settled by the 4th century, there were many variant forms, especially of the central prayer called by the Greeks *anaphora* ("offering") and by the Latins *canon* ("prescribed form"). Liturgical prayers of Basil of Caesarea became widely influential in the East. Later, liturgies were ascribed to local saints and heroes: Jerusalem's to St. James, Alexandria's to St. Mark, and Constantinople's to John Chrysostom. The spirit of Greek liturgies encouraged rich and imaginative prose. Latin style was restrained, with epigrammatic antitheses; and the Roman Church changed from Greek to Latin about AD 370. The Canon of the Latin mass as used in the 6th century was already close to the form it has since retained.

Music also became elaborate, with antiphonal psalm chanting. Some reaction came from those who believed that the music was obscuring the words. Both Athanasius of Alexandria and Augustine defended music on the

Christ as Ruler, with the Apostles and Evangelists (represented by the beasts). The female figures are believed to be either Santa Pudenziana and Santa Praxedes or symbols of the Jewish and Gentile churches. Mosaic in the apse of Santa Pudenziana, Rome, AD 401–417.

condition that the sense of the words remained primary in importance. The Latin theologians Ambrose of Milan, Prudentius, and Venantius Fortunatus provided Latin hymns of distinction. The ascription of the Roman chants (Gregorian) to Pope Gregory I the Great was first made in the 9th century. In the Greek East in the time of Justinian, Romanos Melodos created the kontakion, a long poetic homily.

Architecture was stimulated by Constantine's great buildings at Jerusalem and Rome. The exteriors of these churches remained simple, but inside they were richly ornamented with marble and mosaic, the decoration being arranged on a coherent plan to represent the angels and saints in heaven with whom the church on earth was joining for worship. An enormous number of churches built in and after the 4th century have been excavated. The outstanding buildings that survive largely intact belong to the age of Justinian (6th century) and are at Constantinople and Ravenna.

The veneration of saints led to the production of a specific category of literature known as hagiography. If available, authentic tradition would be used; but if there was none, the writers felt quite free to create a biography from conventional materials and elements of folklore. The lives of saints belong to the poetry of the Middle Ages but are important to the historian as documents of social history.

Historical and polemical writings

The first church historian was Eusebius, bishop of Caesarea in the 4th century, who collected records up to the advent of Constantine. His work was translated and continued in Latin by Tyrannius Rufinus of Aquileia. The history of the church from Constantine to about 430 was continued by three Greek historians: Socrates Scholasticus, Sozomen, and Theodoret (whose works were adapted for the Latin world by Cassiodorus). Ecclesiastical history from 431 to 594 was chronicled by Evagrius Scholasticus. The consequences of Chalcedon as interpreted by Monophysite historians were recorded by Timothy Aelurus, Zacharias Scholasticus, and John of Nikiu.

The monastic movement produced its own special literature, especially the classic *Life of St. Antony* by Athanasius, the collections of sayings of the Desert Fathers, John Climacus' *Heavenly Ladder,* and Moschus' *Spiritual Meadow.*

The Arian and Christological controversies produced important polemical writers—Athanasius, the three Cappadocian Fathers (Basil, Gregory of Nazianzus, and Gregory of Nyssa), Cyril of Alexandria, and Theodoret. After 500, Monophysite theology had eminent figures—Severus of Antioch and the Alexandrian grammarian John Philoponus, who was also a scientist and a commentator on Aristotle. But much theology was non-polemical—*e.g.,* catechesis and biblical commentaries. In the 6th century, "chains" (*catenae*) began to be produced in which the reader was given a summary of the exegesis of a succession of commentators on each verse.

In the West, Hilary of Poitiers, Ambrose of Milan, and, above all, the incomparable scholar Jerome (translator of the standard Latin Bible, or Vulgate) gave Latin theology confidence and so made possible the massive achievement of Augustine—the exquisite prose of his *Confessions* and his majestic treatises *On the Trinity* and *The City of God.*

POLITICAL RELATIONS BETWEEN EAST AND WEST

Reciprocal influences between theology and political thought and action

The old tensions between East and West were sharpened by the quarrels about Chalcedon. In Rome every concession made by Constantinople toward the Monophysites increased the distrust. Justinian's condemnation of the Three Chapters (Fifth Council, Constantinople, 553) was forced on a reluctant West, where it created temporary schisms but was eventually accepted. From the time of Pope Gregory I the Great the papacy—encouraged by the successful mission to the Anglo-Saxons—was looking as much to the Western barbarian kingdoms as to Byzantium.

In the 7th century the Eastern Empire was fighting for its life, first against the Persians and then the Arabs, and the Balkans were occupied by the Slavs. The submergence of Alexandria, Antioch, and Jerusalem under Muslim rule left the patriarch of Constantinople with enhanced authority, whereas the Slav invasions drove a wedge between East and West that encouraged separate developments. The attempts of the Byzantine emperors to force the papacy to accept the Monothelite (one-will) compromise produced a martyr pope, Martin (reigned 649–655); the story of his tortures did nothing to make Rome love the Byzantines. When the Monothelite heresy was finally rejected at the Sixth Council (Constantinople, 680–681), the imprudent pope Honorius (reigned 625–638), who had supported Monothelitism, was expressly condemned, which distressed Roman defenders of papal prerogatives. Greek hostility to the West became explicit in the canons of a council held at Constantinople (Quinisext, 692) that claimed to have ecumenical status but was not recognized in Rome.

From 726 on, Byzantium was absorbed in the iconoclastic (destruction of images) debate, which became a struggle not only to keep icons but also to combat the subjection of the church to the will of the emperor. The imperial attack on images was severely criticized in the West. Yet, after the Greek iconoclasts were condemned at the Seventh Council (Nicaea, 787), the bishops of the Frankish king Charlemagne at the synod of Frankfurt in Germany (794)—with the reluctant consent of Pope Adrian I (reigned 772–795)—censured the decision. A renewed upsurge of iconoclasm in the East (815–843) produced a counterreaction in the West, and ultimately the West accepted the decisions of the Seventh Council. Icons were differently evaluated in the Western churches, where holy pictures were viewed as devotional aids, not, as was the case in the East, virtually sacramental media of salvation.

The greatest protagonist of icons was John of Damascus, an Arab monk in Muslim Palestine, who was the author of an encyclopaedic compendium of logic and theology. Within the empire, Theodore Studites, abbot of the Studium (monastery) near Constantinople, vigorously attacked iconoclasm; he also led a revival of monasticism and stressed the importance of copying manuscripts. His ideals passed to the monastic houses that began to appear on Mount Athos from 963 onward.

The hostility between the iconoclast emperors and the popes encouraged the 8th-century popes to seek a protector. This was provided by the rise of Charles Martel (reigned 719–741) and the Franks. The Frankish kings guarded Western Church interests, and the papal–Frankish alliance reached its climax in the papal coronation of Charlemagne as the first Holy Roman emperor at Rome on Christmas Day, 800—the Holy Roman Empire lasted until 1806. Charlemagne exercised immense authority

over the Western Church, and the revival of church life produced controversies about predestination (Gottschalk, Erigena, Hincmar of Reims) and the Eucharist (Paschasius Radbertus, Ratramnus, Rabanus Maurus). The Christological controversy was revived with a Spanish dispute as to whether Christ was adopted to be Son of God.

In the chaos of the rapid Frankish decline, the papacy was glad to look again to Constantinople for protection. The emperor Basil I (reigned 867–886), founder of the Macedonian dynasty, could not prevent the Arabs from taking Sicily, but he was able to reestablish Byzantine control in southern Italy.

In the 10th century, however, the West passed under the control of the Ottonian dynasty in Germany. The Ottos, accustomed to the system in which great landowners built and owned the churches on their estates as private property, treated Rome and all important sees in this spirit. Bishops were appointed on royal nomination and forbidden to appeal to Rome.

The rise of Islām and the Arab campaign to subjugate unbelievers by military conquest broke upon the Byzantine Empire in 634, just as it was exhausted after defeating Persia. The will to resist was wholly absent. Moreover, the provinces initially overrun, Syria (636) and Egypt (641), were already alienated from the Byzantine government that was persecuting Monophysites in those areas. In 678 and again in 718, the Arabs were at the walls of Constantinople. In the West their defeat by Charles Martel at Poitiers, Fr. (732), limited their advance to the Pyrenees. The Monophysite Copts in Egypt and Syrian Jacobites (followers of Jacob Baradaeus) soon found that they enjoyed greater toleration under Muslim Arabs than under Chalcedonian Byzantines, just as in later times the Greeks were to discover more religious freedom under Turkish than under Latin rule. In the 8th century the Muslims were more a military than a theological threat, and a considerable time passed before Christian and Muslim theologians engaged in serious dialogue.

LITERATURE AND ART OF THE "DARK AGES"

The Monothelite and iconoclastic controversies produced herculean theological endeavours: the criticism of Monothelitism by the monk Maximus the Confessor (580–662) was based upon subtle and very careful considerations of the implications of Chalcedon. The great opponents of iconoclasm, John of Damascus and Theodore Studites, also composed hymns and other theological treatises. Greek mystical theology had an outstanding representative in Symeon the New Theologian (949–1022), abbot of St. Mamas at Constantinople, whose doctrines about light visions anticipated the hesychasm (quietistic prayer methods) of Gregory Palamas in the 14th century. But the most learned theologian of the age was beyond doubt the patriarch Photius (see below *The Photian schism*).

The ending of iconoclasm

Iconoclasm was not an anti-intellectual, anti-art movement. The iconoclasts everywhere replaced figures with the cross or with exquisite patterns. The ending of iconoclasm in 843 (the restoration of orthodoxy), however, liberated the artists adept in mosaic and fresco to portray figures once again, spurring a new revival of decoration. Music also became more elaborate; the kontakion was replaced by the *kanon,* a cycle of nine odes, each of six to nine stanzas and with a different melody. The *kanon* gave more scope to the musicians by providing greater variety. Byzantine hymns were classified according to their mode, and the mode changed each week. Besides John of Damascus and Theodore Studites, the great hymn writers of this period were Cosmas of Jerusalem and Joseph of Studium.

The so-called Dark Ages in the West produced virtually no sculpture or painting—other than illuminated manuscripts, of which marvelous specimens were made (*e.g.,* the Book of Kells and the Lindisfarne Gospels). The Irish and Anglo-Saxon monks did not construct noble buildings but knew how to write and to illuminate a book. In the age of Charlemagne exquisite calligraphy was continued (*e.g.,* the Utrecht Psalter), with intricate ivory and metalwork of superb finesse. Great buildings also began to emerge, partly based on Byzantine models, such as the churches at Ravenna. The Ottonian renaissance in Germany encouraged even more confidently the erection of church buildings, producing such masterpieces as the surviving cathedrals at Hildesheim and Spires and setting out a characteristically German style of architecture.

The barbarian kingdoms soon produced their own Christian literature: Gregory of Tours wrote the history of the Franks, Isidore of Seville that of the Visigoths, and Cassiodorus that of the Ostrogoths. Isidore, utilizing his vast reading, compiled encyclopaedias on everything from liturgical ceremonies to the natural sciences. The outstanding figure of this incipient "nationalist" movement was the English monk Bede, whose *Ecclesiastical History of the English People* was completed in 731 and whose exegetical works came to stand beside Augustine and Gregory I the Great as indispensable for the medieval student.

MISSIONS AND MONASTICISM

Conversion of northern and eastern tribes and peoples

The Arian barbarians soon became Catholics, including, by 700, even the Lombards in northern Italy. There remained immense areas of Europe, however, to which the Gospel had not yet been brought. Gregory I the Great evangelized the Anglo-Saxons, who in turn sent missionaries to northwestern Europe—Wilfrid and Willibrord to what is now The Netherlands, and Boniface to Hesse, Thuringia, and Bavaria. In consequence of Boniface's work in Germany, a mission to Scandinavia was initiated by Ansgar (801–865), and the mission reached Iceland by 996. In the 10th century the mission from Germany moved eastward to Bohemia, to the Magyars, and (from 966) to the Poles. By 1050 most of Europe was under Christian influence with the exception of Muslim Spain.

In the Byzantine sphere, early missions went to the Hunnish tribesmen north of the Caucasus. The Nestorians, entrenched in Persia, carried the Gospel to the Turkmen and across Central Asia to China. In the 9th century the mission to the Slavs began with the work of Cyril and Methodius, who created a Slavonic alphabet and translated the Bible into the Slavonic language. Although their labours in Moravia were undermined by Frankish clergy, it was their achievement that made possible the faith and medieval culture of both Russia and Serbia.

The Benedictine Rule—initiated by Benedict of Nursia—succeeded in the West because of its simplicity and restraint; more formidable alternatives were available in the 6th century. By 800, abbeys existed throughout western Europe, and the observance of Benedict's Rule was fostered by Charlemagne and his son Louis the Pious. These houses, such as Bede's monastery at Jarrow (England) or the foundations of Columban (*c.* 543–615) at Luxeuil (France) and Bobbio (Italy), became centres of study and made possible the Carolingian renaissance of learning. In this renaissance the 8th-century English scholar Alcuin and his monastery at Tours occupy the chief place. Around monasteries and cathedrals, schools were created to teach acceptable Latin, to write careful manuscripts, and to study not only the Bible and writings of the Church Fathers but also science. Scribes developed the beautiful script that was known as Carolingian minuscule. The Carolingian renaissance was short-lived, however, and decay began to set in (850–950) and was not checked until the foundation of the monastery at Cluny (France) in 909.

Monasticism in 9th-century Byzantium was centred upon the Studites, who came to be a faction against the court. A remoter and otherworldly asceticism developed with the foundation of monasteries on Mount Athos (Greece) from 963 onward. A distinctive feature of Athonite monasticism was that nothing female was to be allowed on the peninsula.

THE PHOTIAN SCHISM AND THE GREAT EAST–WEST SCHISM

The Photian schism. The end of iconoclasm (843) left a legacy of faction. Ignatius, patriarch of Constantinople intermittently from 847 to 877, was exiled by the government in 858 and replaced by Photius, a scholarly layman who was head of the imperial chancery—he was elected patriarch and ordained within six days. Ignatius' supporters dissuaded Pope Nicholas I (reigned 858–867) from recognizing Photius. Nicholas was angered by Byzantine missions among the Bulgars, whom he regarded as be-

Virgin Mary with (left) Justinian, holding a model of Hagia Sophia, and (right) Constantine, holding a model of the city of Constantinople. Mosaic from Hagia Sophia, 9th century.

longing to his sphere. When Nicholas wrote to the Bulgars attacking Greek practices, Photius replied by accusing the West of heretically altering the creed in saying that the Holy Spirit proceeds from the Father and from the Son (*Filioque*). He declared Pope Nicholas deposed (867), but his position was not strong enough for such imprudence.

A new emperor, Basil the Macedonian, reinstated Ignatius; and in 869 Nicholas' successor, Adrian II (reigned 867–872), condemned Photius and sent legates to Constantinople to extort submission to papal supremacy from the Greeks. The Greeks resented the papal demands, and when Ignatius died in 877 Photius quietly became patriarch again. Rome (at that moment needing Byzantine military support against Muslims in Sicily and southern Italy) reluctantly agreed to recognize Photius, but on the condition of an apology and of the withdrawal of Greek missions to the Bulgars. Photius acknowledged Rome as the first see of Christendom, discreetly said nothing explicitly against the *Filioque* clause, and agreed to the provision that the Bulgars could be put under Roman jurisdiction providing that Greek missions were allowed to continue.

The main issue in the Photian schism was whether Rome possessed monarchical power of jurisdiction over all churches (as Nicholas and Adrian held), or whether Rome was the senior of five semi-independent patriarchates (as Photius and the Greeks thought) and therefore could not canonically interfere with the internal affairs of another patriarchate.

The great East–West schism. The mutual distrust shown in the time of Photius erupted again in the middle of the 11th century after papal enforcement of Latin customs upon Greeks in southern Italy. The patriarch of Constantinople, Michael Cerularius, closed Latin churches in Constantinople as a reprisal. Cardinal Humbert came from Italy to protest, was accorded an icy reception, and left a bull of excommunication (July 16, 1054) on the altar of the great church of Hagia Sophia. The bull anathematized (condemned) Michael Cerularius, the Greek doctrine of the Holy Spirit, the marriage of Greek priests, and the Greek use of leavened bread for the Eucharist.

The significance of the date 1054

At the time, the breach was treated as a minor storm in which both sides had behaved with some arrogance. As Greeks and Latins became more estranged, however, people looked back on the events of 1054 as the moment of the final breach between East and West. (Not until Dec. 7, 1965, were the mutual excommunications of 1054 abolished, by Pope Paul VI and the ecumenical patriarch Athenagoras I.) (H.Cha.)

FROM THE SCHISM TO THE REFORMATION

Differences between the Eastern and Western churches. A major factor in the consolidation and expansion of Christianity in the West was the growth in the prestige and power of the bishop of Rome. Pope Leo I the Great made the primacy of the Roman bishop explicit both in theory and in practice and must be counted as one of the most important figures in the history of the centralization of authority in the church. The next such figure was Gregory I the Great, whose work shaped the worship, the thought, and the structure of the church as well as its temporal wealth and power.

Even while still a part of the universal church, Byzantine Christianity had become increasingly isolated from the West by difference of language, culture, politics, and religion and followed its own course in shaping its heritage. The Eastern churches never had so centralized a polity as did the church in the West but developed the principle of the administrative independence or "autocephaly" of each national church. During the centuries when Western culture was striving to domesticate the German tribes, Constantinople, probably the most civilized city in Christendom, blended classical and Christian elements with a refinement that expressed itself in philosophy, the arts, statecraft, jurisprudence, and scholarship. A thinker such as Michael Psellus in the 11th century, who worked in several of these fields, epitomizes this synthesis. It was from Byzantine rather than from Roman missionaries that Christianity came to most of the Slavic tribes, including some who eventually sided with Rome rather than Constantinople; Byzantium was also the victim of Muslim aggressions throughout the period known in the West as the Middle Ages. Following the pattern established by the

Caesaropapism

emperors Constantine and Justinian, the relation between church and state in the Byzantine empire coordinated the two in such a way as to sometimes subject the life and even the teaching of the church to the decisions of the temporal ruler—the phenomenon often, though imprecisely, termed caesaropapism.

All these differences between the Eastern and Western parts of the church, both the religious differences and those that were largely cultural or political, came together to cause the schism between the two. The break in 1054 was followed by further evidences of alienation—in the 13th century, in the sack of Constantinople by Western Christians in 1204 and the establishment of the Latin patriarchate there; and in the 15th century, after the failure of the union of Florence and after the fall of Constantinople to the Turks in 1453.

Papacy and empire. Conflict with the East was both a cause and an effect of the distinctive development of Western Christianity during the Middle Ages. If popes Leo I and Gregory I may be styled the architects of the medieval papacy, popes Gregory VII (reigned 1073–85) and Innocent III (reigned 1198–1216) should be called its master builders. Gregory VII reformed both the church and the papacy from within, establishing the canonical and moral authority of the papal office when it was threatened by corruption and attack; in the pontificate of Innocent III the papal claims to universality reached their zenith at all levels of the life of the church. Significantly, both these popes were obliged to defend the papacy against the Holy Roman emperor and other temporal rulers. The battle between the church and the empire is a persistent theme in the history of medieval Christianity. Both the involvement of the church in feudalism and the participation of temporal rulers in the Crusades can be read as variations on this theme. Preoccupied as they usually are with the history of the church as an institution and with the life and thought of the leaders of the church, the documentary sources of knowledge about medieval Christianity make it difficult for the social historian to descry "the religion of the common man" during this period. Both the "age of faith" depicted by neo-Gothic Romanticism and the "Dark Ages" depicted by secularist and Protestant polemics are gross oversimplifications of history. Faith there was during the Middle Ages, and intellectual darkness and superstition too; but only that historical judgment of medieval Christianity is valid that discerns how subtly faith and superstition can be blended in human piety and thought.

Scholasticism

Medieval thought. No product of medieval Christianity has been more influential in the centuries since the Middle Ages than medieval thought, particularly the philosophy and theology of Scholasticism, whose outstanding exponent was Thomas Aquinas (1224/25–1274). The theology of Scholasticism was an effort to harmonize the doctrinal traditions inherited from the Fathers of the early church and to relate these traditions to the intellectual achievements of classical antiquity. Because many of the early Fathers both in the East and in the West had developed their theologies under the influence of Platonic modes of thought, the reinterpretation of these theologies by Scholasticism required that the doctrinal content of the tradition be disengaged from the metaphysical assumptions of Platonism. For this purpose the recovery of Aristotle—first through the influence of Aristotelian philosophers and theologians among the Muslims, and eventually, with help from Byzantium, through translation and study of the authentic texts of Aristotle himself—seemed providential to the Scholastic theologians. Because it managed to combine a fidelity to Scripture and tradition with a positive, though critical, attitude toward the "natural" mind, Scholasticism is a landmark both in the history of Christianity and in the history of Western culture, as a symbol (depending upon one's own position) either of the Christianization of society and culture or of the betrayal of Christianity to the society and culture of the Middle Ages.

Reformation. The latter interpretation of Scholasticism and of the medieval church itself animated the Protestant Reformation. Protestantism differed from the various protest movements during the later Middle Ages by the thoroughness of its polemic against the ecclesiastical, theological, and sacramental developments of Western Catholicism. Initially the Protestant Reformers maintained the hope that they could accomplish the reformation of the doctrine and life of the church from within, but this proved impossible either because of the intransigency of the church, the extremism of the Protestant movements, or the political and cultural situation—or because of all of these factors. The several parties of the Reformation may be conveniently classified according to the radicalism of their protest against medieval theology, piety, and polity. The Anglican Reformers, as well as Martin Luther and his movement, were, in general, the most conservative in their treatment of the Roman Catholic tradition; John Calvin and his followers were less conservative; the Anabaptists and other groups in the left wing of the Reformation were least conservative of all. Despite their deep differences, almost all the various Reformation movements were characterized by an emphasis upon the Bible, as distinguished from the church or its tradition, as the authority in religion; by an insistence upon the sovereignty of free grace in the forgiveness of sins; by a stress upon faith alone, without works, as the preconditions of acceptance with God; and by the demand that the laity assume a more significant place in both the work and the worship of the church.

Characterization of Reformation movements

The Reformation was launched as a movement within the established Christianity that had prevailed since Constantine. It envisaged neither schism within the church nor the dissolution of the Christian culture that had developed for more than a millennium. But when the Reformation was over, both the church and the culture had been radically transformed. In part this transformation was the effect of the Reformation; in part it was the cause of the Reformation. The voyages of discovery, the beginnings of a capitalist economy, the rise of modern nationalism, the dawn of the scientific age, the culture of the Renaissance—all these factors, and others besides, helped to break up the "medieval synthesis." Among these factors, however, the Reformation was one of the most important and, certainly for the history of Christianity, the most significant. For the consequences of the Reformation, not in intention but in fact, were a divided Christendom and a secularized West. Roman Catholicism, no less than Protestantism, has developed historically in the modern world as an effort to adapt historic forms to the implications of these consequences. Established Christianity, as it had been known in the West since the 4th century, ended after the Reformation, though not everywhere at once.

MODERN CHRISTIANITY

Paradoxically, the end of "established Christianity" in the old sense resulted in the most rapid and most widespread expansion in the history of the church. The Christianization of the Americas and the evangelization of Asia, Africa, and Australasia for the first time gave geographic substance to the Christian title "ecumenical." Growth in areas and in numbers, however, need not be equivalent to growth in influence. Despite its continuing strength throughout the modern period, Christianity retreated on many fronts and lost much of its prestige and authority both politically and intellectually.

During the formative period of modern Western history, roughly from the beginning of the 16th to the middle of the 18th century, Christianity participated in many of the movements of cultural and political expansion. The explorers of the New World were followed closely by missionaries—that is, when the two were not in fact identical. Protestant and Roman Catholic clergymen were prominent in politics, letters, and science. Although the rationalism of the Enlightenment alienated many people from the Christian faith, especially among the intellectuals of the 17th and 18th centuries, those who were alienated often kept a loyalty to the figure of Jesus or to the teachings of the Bible even when they broke with traditional forms of Christian doctrine and life. Citing the theological conflicts of the Reformation and the political conflicts that followed upon these as evidence of the dangers of religious intolerance, representatives of the Enlightenment gradually introduced disestablishment, toleration, and religious liberty into most Western countries; in this movement

they have been joined by Christian individuals and groups that advocated religious freedom not out of indifference to dogmatic truth but out of a concern for the free decision of personal faith.

The Counter-Reformation

The state of Christian faith and life within the churches during the 17th and 18th centuries both reflected and resisted the spirit of the time. Even though the Protestant Reformation had absorbed some of the reformatory energy within Roman Catholicism, the theology and morals of the church underwent serious revision in the Roman Catholic Counter-Reformation. Fighting off the attempts by various countries to establish national Catholic churches, the papacy sought to learn from the history of the Reformation and to avoid the mistakes that had been made then. Protestantism in turn discovered that separation from Rome did not necessarily inoculate it against many of the trends that it had denounced in Roman Catholicism. The orthodox dogmatics of the 17th century both in Lutheranism and in the Reformed churches displayed many features of medieval Scholasticism, despite the attacks of the Reformers upon the latter. Partly as a compensation for the overemphasis of orthodoxy upon doctrine at the expense of morals, Pietism summoned Protestant believers to greater seriousness of faith and purpose. Valid though its summons was, the subjectivity of Pietism unwittingly played into the hands of its enemies, helping to make it possible for the rationalism of the Enlightenment to undermine traditional Christian belief.

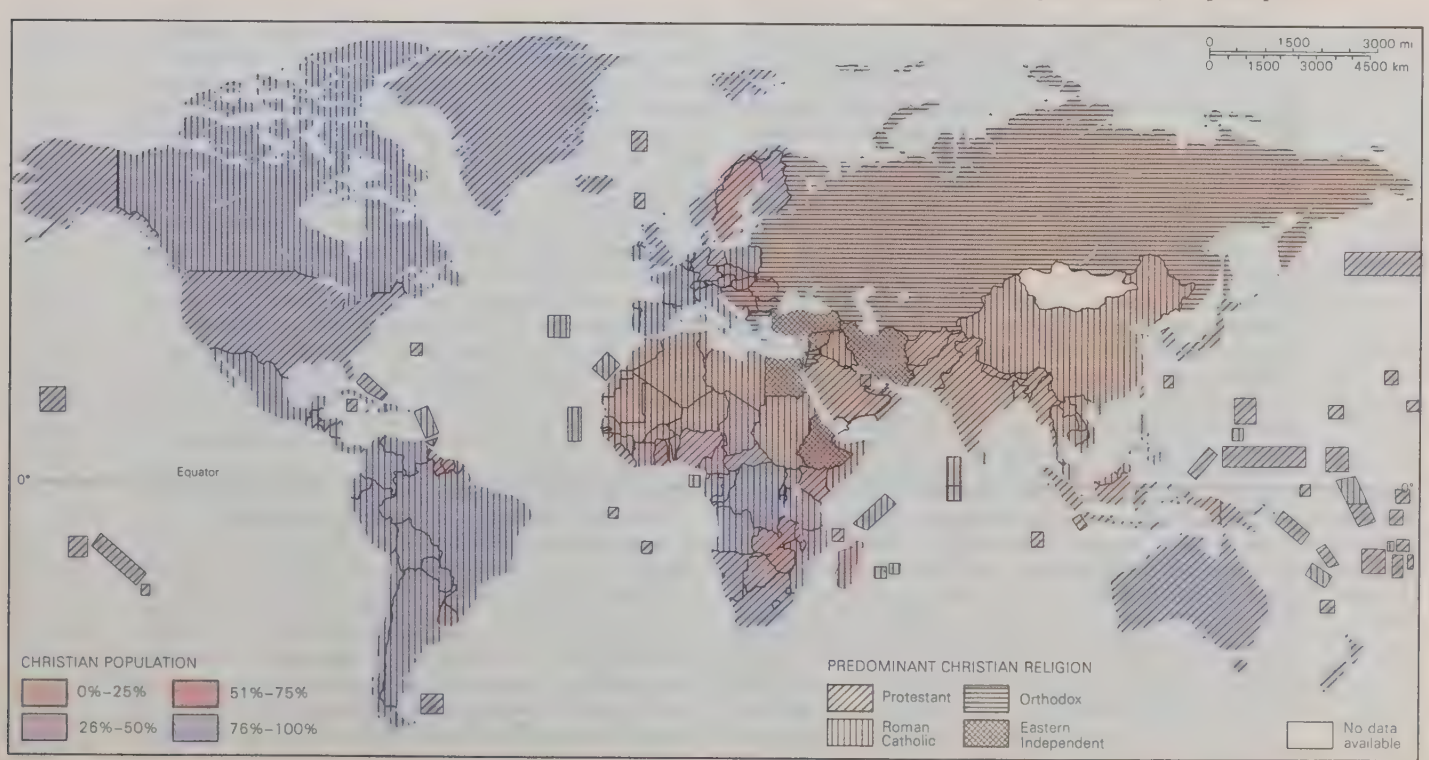
In alliance with the spirit of the Enlightenment, the revolutions of the 18th, 19th, and 20th centuries aided this process of undermining Christianity. Roman Catholicism in France, Eastern Orthodoxy in Russia, and Protestantism in former European colonies in Africa and Asia were identified—by their enemies if not also by themselves—as part of the ancien régime and were nearly swept away with it. As the discoveries of science proceeded, they clashed with old and cherished notions about the doctrine of creation, many of which were passionately supported by various leaders of organized Christianity. The age of the revolutions—political, economic, technological, intellectual—was an age of crisis for Christianity. It was also an age of opportunity. The critical methods of modern scholarship, despite their frequent attacks upon traditional Christian ideas, helped to produce editions of the chief documents of the Christian faith—the Bible and the writings of the Fathers and Reformers—and to arouse an unprecedented interest in the history of the church. The 19th century has been called the great century in the history of Christian missions, both Roman Catholic and Protestant. By the very force of their attacks upon Christianity, the critics of the church helped to arouse within the church new apologists for the faith, who creatively reinterpreted it in relation to the new philosophy and science of the modern period. The 20th century saw additional challenges to the Christian cause in the form of Communism, of resurgent world religions, and of indifference. Both the relation of church and state and the missionary program of the churches thus demanded reconsideration. But the 20th century also saw renewed efforts to heal the schisms within Christendom. The ecumenical movement began within Protestantism and Anglicanism, eventually included some of the Eastern Orthodox churches, and, especially since the second Vatican Council (1962–65), has engaged the sympathetic attention of Roman Catholicism as well.

THE MODERN DENOMINATIONS

By the late 20th century Christianity had become the most widely disseminated faith on Earth. Virtually no nation has remained unaffected by the activities of Christian missionaries, although in many countries Christians are only a small fraction of the total population. Most of the countries of Asia and of Africa have Christian minorities, some of which, as in India and even in China, number several million members. The concentration of Christians, however, remains in the domain of Western culture. Each major division of Christianity—Eastern Orthodoxy, Roman Catholicism, and Protestantism—is treated in the *Macropædia* in a separate article where its history, tenets, and practices receive a fuller exposition than this article can give them and where a bibliography on the denominations of the division is supplied. The purpose here is to provide an overview of the principal divisions and thus to set the articles about the individual traditions into their proper context.

Church organization

Roman Catholicism. The Roman Catholics in the world outnumber all other Christians combined. They are organized in an intricate system that spans the structure of the church from the local parish to the papacy. Under the central authority of the papacy, the church is divided into dioceses, whose bishops act in the name and by the authority of the pope but retain considerable administrative freedom within their individual jurisdictions; the principle



World distribution of Christianity by country.

of "collegiality" articulated by the second Vatican Council has expanded that freedom. Similarly, the parish priest stands as the executor of papal and diocesan directives. Alongside the diocesan organization and interacting with it is a chain of orders, congregations, and societies; all of them are, of course, subject to the pope, but they are not directly responsible to the bishop as are the local parishes. It would, however, be a mistake to interpret the polity of the Roman Catholic Church in so purely an organizational manner as this. For Roman Catholic polity rests upon a mandate that is traced to the action of Jesus Christ himself, when he invested Peter and, through Peter, his successors with the power of the keys in the church. Christ is the invisible head of his church, and by his authority the pope is the visible head.

This interpretation of the origin and authority of the church determines both the attitude of Roman Catholicism to the rest of Christendom and its relation to the social order. Believing itself to be the true church of Jesus Christ on earth, it cannot deal with other Christian traditions as equals without betraying its very identity. This does not mean, however, that anyone outside the visible fellowship of the Roman Catholic Church cannot be saved; nor does it preclude the presence of "vestiges of the church" in the other Christian bodies. At the second Vatican Council the Roman Catholic Church strongly affirmed its ties with its "separated brethren" both in Eastern Orthodoxy and in the several Protestant churches. As the true church of Christ on earth, the Roman Catholic Church also believes itself responsible for the proclamation of the will of God to organized society and to the state. This role brought the church into conflict with the state throughout church history. Yet the political activities of individual churchmen must not be confused with the fundamental obligation of the church, as the "light of the world" to which the revelation of God has been entrusted, to address the meaning of that revelation and of the moral law to the nations, and to work for a social and political order in which both revelation and the moral law can function.

Both in democratic and in totalitarian societies, whether Fascist or Communist, during the 20th century, the relation of the Roman Catholic Church to the state continued to engage the attention of political leaders and of prelates and theologians.

Doctrine. The understanding that Roman Catholicism has of itself, its interpretation of the proper relation between the church and the state, and its attitude toward other Christian traditions are all based upon Roman Catholic doctrine. In great measure this doctrine is identical with that confessed by orthodox Christians of every label and consists of the Bible, the dogmatic heritage of the ancient church as laid down in the historic creeds and in the decrees of the ecumenical councils, and the theological work of the great doctors of the faith in the East and West. If, therefore, the presentation of the other Christian traditions in this article compares them with Roman Catholicism, this comparison has a descriptive rather than a normative function; for, to a considerable degree, Protestantism and Eastern Orthodoxy have often defined themselves in relation to Roman Catholicism. In addition, most Christians past and present do have a shared body of beliefs about God, Christ, and the way of salvation.

Roman Catholic doctrine is more than this shared body of beliefs, as is the doctrine of each of the Christian groups. It is necessary here to mention only the three distinctive doctrines that have achieved definitive formulation during the 19th and 20th centuries: the infallibility of the pope, the immaculate conception, and bodily assumption of the Virgin Mary. On most other major issues of Christian doctrine, Roman Catholicism and Eastern Orthodoxy are largely in agreement, while Protestantism differs from both Eastern Orthodoxy and Roman Catholicism on several issues. For example, Roman Catholic theology defines and numbers the sacraments differently from Orthodox theology; but, over against Protestantism, Roman Catholic doctrine insists, as does Eastern Orthodoxy, upon the centrality of the seven sacraments—baptism, confirmation, Eucharist, extreme unction, penance, matrimony, and holy orders—as channels of divine grace.

Three distinctive doctrines of Roman Catholicism

Liturgy. The Roman Catholic doctrine of the sacraments is a summary, in liturgical form, of that which is affirmed by Roman Catholic liturgy. The church is not primarily an organization, nor is it a school of doctrine. It is the place where God approaches humanity through grace and where humanity approaches God through worship. Hence the focus of Roman Catholic piety is the Eucharist, which is both a sacrament and a sacrifice. Other forms of corporate worship and of private devotion radiate from this point of central focus. The obligations of church membership are also derived from the sacramental system, either as preparations for worthy participation in it or as expressions of the obedience sustained by it. Instruction in these obligations and in the implication of the faith for the moral and intellectual life is the responsibility of Roman Catholic educational institutions all over the world. The missions of the church and its institutions of mercy, like the schools, are largely in the hands of religious orders.

The Eastern churches. Separated from the West, the Orthodox churches of the East have developed their own way for half of Christian history. Each national church is autonomous. The "ecumenical patriarch" of Constantinople is not the Eastern pope but merely the first in honour among equals in jurisdiction. Eastern Orthodoxy interprets the primacy of Peter and therefore that of the pope similarly, denying the right of the pope to speak and act for the entire church by himself, without a church council and without his episcopal colleagues. Because of this polity Eastern Orthodoxy has identified itself more intimately with national cultures and with national regimes than has Roman Catholicism. Therefore the history of church–state relations in the East has been very different from the Western development, because the church in the East has sometimes tended toward the extreme of becoming a mere instrument of national policy while the church in the West has sometimes tended toward the extreme of attempting to dominate the state. The history of ecumenical relations between Eastern Orthodoxy and Protestantism during the 20th century was also different from the history of Protestant–Roman Catholic relations. While keeping alive their prayer for an eventual healing of the schism with the Latin Church, some of the Orthodox churches have established communion with Anglicanism and with the Old Catholic Church and have participated in the conferences and organizations of the World Council of Churches.

Doctrinal authority

Doctrinal authority for Eastern Orthodoxy resides in the Scriptures, the ancient creeds, the decrees of the first seven ecumenical councils, and the tradition of the church. In addition to the issues mentioned in the discussion of Roman Catholicism above, the chief dogmatic difference between Roman Catholic and Eastern Orthodox thought is on the question of the procession of the Holy Spirit from the Father and from the Son, or the *Filioque.*

But "orthodoxy," in the Eastern use of the term, means primarily not a species of doctrine but a species of worship. The Feast of Orthodoxy on the first Sunday of Lent celebrates the end of the iconoclastic controversies and the restoration to the churches of the icons, which are basic to Orthodox piety. In Orthodox churches (as well as in those Eastern churches that have reestablished communion with Rome), the most obvious points of divergence from general Western practice are the Byzantine liturgy, the right of the clergy to marry before ordination, though bishops may not be married, and the administration to the laity of both species in the Eucharist at the same time by the method of intinction.

The rediscovery of Eastern Orthodox liturgy and piety by Western Christians is an interesting by-product of the ecumenical contacts of the 19th century and of the Russian Revolution. Russian Orthodox scholars and theologians emigrated to the West, especially to France and the United States, where they became active participants in the dialogue among the separated churches.

Protestantism. Formulating a definition of Protestantism that would include all its varieties has long been the despair of Protestant historians and theologians, for there is greater diversity within Protestantism than there is between some forms of Protestantism and some non-Protestant Christianity. For example, a high-church An-

glican or Lutheran has more in common with an Orthodox theologian than with a Baptist theologian. Amid this diversity, however, it is possible to define Protestantism formally as non-Roman Western Christianity and to divide most of Protestantism into four major confessions or confessional families—Lutheran, Anglican, Reformed, and Free Church.

Four major Protestant confessions

Lutheranism. The largest of these non-Roman Catholic denominations in the West is the Lutheran Church. The Lutheran churches in Germany, in Scandinavian countries, and in the Americas are distinct from one another in polity, but almost all of them are related through various national and international councils, of which the Lutheran World Federation is the most comprehensive. Doctrinally, Lutheranism sets forth its distinctive position in the Book of Concord, especially in the Augsburg Confession. A long tradition of theological scholarship has been responsible for the development of this position into many and varied doctrinal systems. Martin Luther moved conservatively in this reformation of the Roman Catholic liturgy, and the Lutheran Church, though it has altered many of his liturgical forms, has remained a liturgically traditional church. Most of the Lutheran churches of the world have participated in the ecumenical movement and are members of the World Council of Churches, but Lutheranism has not moved very often across its denominational boundaries to establish full communion with other bodies. The prominence of Lutheran societies in the history of missions during the 18th and 19th centuries, after the relative inactivity following the Reformation, gave an international character to the Lutheran Church; so did the development of strong Lutheran churches in North America, where the traditionally German and Scandinavian membership of the church was gradually replaced by a more cosmopolitan constituency.

Anglicanism. The Anglican Communion is not only the established Church of England but also the Christian denomination of many believers throughout the world. Like Lutheranism, Anglicanism has striven to retain whatever it could of the Roman Catholic tradition of liturgy and piety, but after the middle of the 19th century the Oxford Movement in Anglicanism went much further in the restoration of ancient liturgical usage and doctrinal belief. Although the Catholic revival also served to rehabilitate the authority of tradition in Anglican theology generally, great variety continued to characterize the theologians of the Anglican Communion. Anglicanism is set off from most other non-Roman churches in the West by its retention of and its insistence upon the apostolic succession of ordaining bishops. The Anglican claim to this apostolic succession, despite its repudiation by Pope Leo XIII in 1896, has largely determined the role of the Church of England in the discussions among the churches. Anglicanism has often taken the lead in inaugurating such discussions, but in such statements as the Lambeth Quadrilateral it has demanded the presence of the historic episcopate as a prerequisite to the establishment of full communion. During the 19th and 20th centuries many leaders of Anglican thought were engaged in finding new avenues of communication with industrial society and with the modern intellectual. The strength of Anglicanism in the New World and in the younger churches of Asia and Africa confronted this communion with the problem of deciding its relation to new forms of Christian life in these new cultures. As its centuries-old reliance upon the establishment in England was compelled to retrench, Anglicanism discovered new ways of exerting its influence and of expressing its message.

Presbyterian and Reformed Churches. Protestant bodies that owe their origins to the reformatory work of John Calvin and his associates in various parts of Europe are often termed Reformed, particularly in Germany, France, and Switzerland. In Britain and in the United States they have usually taken their name from their distinctive polity and have been called Presbyterian. They are distinguished from both Lutheranism and Anglicanism by the thoroughness of their separation from Roman Catholic patterns of liturgy, piety, and even doctrine. Reformed theology has tended to emphasize the sole authority of the Bible with more rigour than has characterized the practice of Anglican or Lutheran thought, and it has looked with deeper suspicion upon the symbolic and sacramental traditions of the Catholic centuries. Perhaps because of its stress upon biblical authority, Reformed Protestantism has sometimes tended to produce a separation of churches along the lines of divergent doctrine or polity, by contrast with the inclusive or even latitudinarian churchmanship of the more traditionalistic Protestant communions. This understanding of the authority of the Bible has also led Reformed Protestantism to its characteristic interpretation of the relation between church and state, sometimes labeled theocratic, according to which those charged with the proclamation of the revealed will of God in the Scriptures (*i.e.,* the ministers) are to address this will also to civil magistrates; Puritanism in England and America gave classic expression to this view. As the church is "reformed according to the Word of God," so the lives of the individuals in the church are to conform to the Word of God; hence the Reformed tradition has assigned great prominence to the cultivation of moral uprightness among its members. During the 20th century most of the Reformed churches of the world took an active part in the ecumenical movement.

Emphasis on the Bible as sole authority

Free churches. In the 19th century the term Free churches was applied in Great Britain to those Protestant bodies that did not conform to the establishment, such as Congregationalists, Methodists, and Baptists (and Presbyterians in England); but since that time it has come into usage among the counterparts to these churches in the United States, where each of them has grown larger than its British parent body. Just as the Reformed denominations go beyond both Anglicanism and Lutheranism in their independence of Roman Catholic traditions and usages, so the Free churches have tended to reject some of the Roman Catholic remnants also in classical Presbyterian worship and theology. Baptists and Congregationalists see the local congregation of gathered believers as the most nearly adequate visible representation of Christ's people on earth. The Baptist requirement of free personal decision as a prerequisite of membership in the congregation leads to the restriction of baptism to believers (*i.e.,* those who have made and confessed such a decision of faith) and therefore to the repudiation of infant baptism; this in turn leads to the restriction of communion at the Eucharist to those who have been properly baptized. In Methodism the Free-church emphasis upon the place of religious experience and upon personal commitment leads to a deep concern for moral perfection in the individual and for moral purity in the community. The Disciples of Christ, a Free church that originated in the United States, makes the New Testament the sole authority of doctrine and practice in the church, requiring no creedal subscription at all; a distinctive feature of their worship is their weekly celebration of Communion. Emphasizing as they do the need for the continuing reformation of the church, the Free churches have, in most (though not all) cases, entered into the activities of interchurch cooperation and have provided leadership and support for the ecumenical movement. This cooperation—as well as the course of their own historical development from spontaneous movements to ecclesiastical institutions possessing many of the features that the founders of the Free churches had originally found objectionable in the establishment—has made the question of their future role in Christendom a central concern of Free churches on both sides of the Atlantic.

Other churches and movements. In addition to these major divisions of Protestantism, there are other churches and movements not so readily classifiable; some of them are quite small, but others number millions of members. These churches and movements would include, for example, the Society of Friends (or Quakers), known both for their cultivation of the "Inward Light" and for their pacifism; the Unitarian Universalist body, which does not consistently identify itself as Christian; Christian Science; Unity and other theosophic movements, which blend elements from the Christian tradition with practices and teachings from other religions; Pentecostal churches and churches of divine healing, which profess to return to

primitive Christianity; and many independent churches and groups, most of them characterized by a free liturgy and a fundamentalist theology. Separately and together, these groups illustrate how persistent has been the tendency of Christianity since its beginnings to proliferate parties, sects, heresies, and movements. They illustrate also how elusive is the precise demarcation of Christendom, even for those observers whose definition of normative Christianity is quite exact. (J.J.Pe.)

Christian doctrine

THE MEANING OF DOGMA

Christian doctrine has often taken a specific form called "dogma." Although the term originally referred to "that which is regarded as good," the early Christians employed it to mean a teaching that came from divine revelation and was authoritatively defined as true by the church. The collection of such teachings is also referred to as dogma. Taken together, these teachings were seen to be vital for the salvation of Christians. To deviate from any of the dogmas was considered dangerous to salvation and to the life of the church.

Whereas in some periods, including early Christian times and whenever Christianity was dominant in the culture, those in authority and most of the faithful thought of dogma in positive terms, it has often suffered criticism in modern times. The concept seems to militate against the freedom of inquiry by which moderns seek truth, and it can be easily transformed into an instrument of state in officially Christian societies, where deviations can be punished as treason. In addition, to some Christians, the great German scholar Adolf von Harnack among them, dogma appeared to be a corruption of the essentially simple faith of Jesus and the early Christians. It was seen as an intrusion of Greek philosophy, an "acute Hellenization" that obscured the Christian truth it had set out to guard.

The Hellenization of the Christian message

Without question, some Hellenization did take place, and dogma was often misused. Yet it is difficult to picture a rapidly growing body such as the early church existing permanently without efforts to provide authoritative definitions of the ideas its leadership regarded as true and for which they would be responsible. Therefore, any attempt to discern the meaning of Christian faith through the ages necessarily involves an understanding of the reasons for the existence of dogma and a comprehension of what the main dogmatic teachings in the various times and places of the church's life have been.

The early Christian definitions of dogma drew on Greek thought in general and, in some cases, on Neoplatonic philosophy in particular. Out of this borrowing of categories not derived from the Bible came basic, indeed crucial, definitions concerning both the Trinity and Christology. Historians, particularly in the modern West, have appraised and criticized these applications of Greek thought.

The Eastern Orthodox Church, however, views the formation of dogma not as a purely human process (which would have to be judged a falsification of divine truths) but as a divine–human process in which the Holy Spirit, proceeding from God, and the human spirit, proceeding from history, participate. According to this view, the origin of revelation in God means that the truths of dogma are divine, eternal, and immutable.

Concepts of dogma in the various churches

Dogma has varying positions in the different churches. Whereas in Protestant churches doctrines and creeds generally are associated primarily with theology and preaching, in the Eastern Orthodox Church dogma is directly related to the liturgical life of the church. The confessions of faith of the Orthodox Church are not to be understood as abstract formulations of a pure doctrine but as hymns of worship incorporated appropriately in the liturgy.

In contrast to the rather definitive dogmatic development in the Roman Catholic Church and Reformation Christianity, a much greater freedom in the interpretation of dogma is guaranteed in the Eastern Church. Even the formulation of a dogma by an ecumenical council in Eastern Orthodoxy does not have a binding legal character until it is received within the total ecumenical church consciousness.

Orientation of the Western churches. From their inception, the Western churches have viewed the fundamental relationship between God and humanity primarily in judicial terms. Characteristically, the Apostle Paul in his letter to the Romans depicted the experience of salvation as justification. To be justified means to receive the verdict "just" or "righteous," whether from a judge—the law court was the source of the Pauline theological image—or from God, as witnessed to in the Christian scheme of salvation. The Roman Church was strongly Jewish–Christian in character and combined this character without difficulties with the basic orientation of the Roman view of religion—*i.e.,* the relationship between God and humanity was primarily a judicial one. The legal character of Roman religion was expressed in the fact that the efficacy of the state cult ceremonies was dependent upon the strictest observation of a wide variety of regulations. Later developments of Roman Catholic Christianity depended largely upon the basis of this legal thinking. In Rome the specifically Western sacrament of penance developed in the context of legal terminology and was dominated by the idea of justification.

The relationship between God and humanity as judicial

In the judicial foundation of the sacrament of penance (in which an offender might regain a right relationship with the church through the performance of certain works), later possibilities of corruption are built in (*e.g.,* the indulgence, or remission of temporal punishment upon the granting of absolution by a priest and, perhaps, the payment of a fee or performance of certain works). The indulgence resulted from a fusion of Roman and German legal thought.

Just as judicial notions dominated divine–human personal relationships, so they helped shape questions of authority. Thus the Western notions of both church and priesthood acquired a legal cast. The church understands itself as a spiritual–judicial institution, founded by Christ but perpetuated by structures that often resemble those in human government. The priest is the legitimate bearer of this legal order. In the sphere of this kind of legal thinking the papacy and the doctrine of papal primacy developed. The idea of a jurisdictional primacy played a prominent role in the formation of the doctrine of the papacy. Kingly authority passed over to the priestly, the emperor's crown to the episcopal tiara. At the high point of this development, Pope Boniface VIII in 1302 proclaimed himself the highest ruler of the world, to whom Christ has committed both swords, the spiritual and the temporal. This judicial idea is also reflected in the individual priest's consciousness of his office. Ordination by the bishop confers upon the priest a legal authority to administer the sacraments and to exercise the power of the keys. In consciousness of this legal process the priest absolves the sinner from his sins in confession with the words: "I absolve you."

On the basis of this legal consciousness the Western church also developed its own canon law. Canon law in the West penetrated, indeed dominated, the societal sphere of life much more strongly than it did in the Orthodox Church (see below *Canon law*).

Influence of judicial thinking in Western theology and monasticism

Judicial thinking was similarly significant in the theology of the West. Whereas the East never assigned a decisive significance to the justification doctrine of the Apostle Paul, in the West the theologian Tertullian introduced a series of fundamental juridical concepts into theology (*e.g.,* persona—a legal person). For Augustine, the doctrine of justification was the foundation of his view of the relationship of humans to God as well as of his view of sin, guilt, and grace. For Anselm, archbishop of Canterbury from 1093 to 1109, the existing, valid judicial relationship between God and humans had to be the basic presupposition of all theological thinking. Anselm believed that he could cogently derive—even for unbelievers—the truth of Christian faith and the necessity of the incarnation of God from the idea of satisfaction (*i.e.,* that one could make satisfaction for a crime against another).

Western monasticism also received its special imprint from judicial thought. Sanctification is believed to be accomplished by practicing good works and, particularly, surplus works or "works of supererogation"—*i.e.,* those that the saint performs over and above those necessary

for the satisfaction of his own sins. Alexander of Hales (*c.* 1170/85–1245), an English theologian and philosopher, advanced the doctrine that out of the works of satisfaction of Christ, the saints, and the martyrs, the church has collected a "treasury of good works," which the pope properly has at his disposal.

This judicial thinking is even extended to the eschatological expectation and the view of the last things, for many of the biblical notions about God acting out of love in the final dealings with humans tend to be challenged or obscured by overpowering pictures of divine righteousness. At the end of the world stands the radical separation of humanity into the redeemed, who enter eternal blessedness, and the damned, who are delivered over to eternal punishment. According to the Roman Catholic view, sinners improve their prospects by acceptance of an interim state, in which they can ameliorate their positions in respect to God before the Last Judgment by making amends for their sins. Through indulgences, masses for the dead, and other acts, the church expanded its spiritual–judicial authority even to this realm of the departed souls of purgatory (the state of existence after death in which temporal punishment is meted out). Although the doctrine of purgatory remains among the official teachings of contemporary Roman Catholicism, it has been downplayed in much popular expression and belief. The pictures of God acting beneficently toward sinners have progressively challenged the medieval and early modern accent on God acting punitively.

Orientation of the Eastern churches. In the New Testament, ideas later regarded as mystical are associated with the writings and experiences of Paul and in the Gospel and Letters associated with the name John. The Orthodox churches have encouraged a piety that elevates these mystical themes and makes them prominent. In these Eastern settings justification is less frequently considered. Instead, the idea that humans are to partake in the nature of the Godhead—to be holy, reborn, newly created, resurrected, and transfigured—comes to the fore. Indeed, not only humanity but also the whole of creation partakes of this potentially transforming character. Orthodox mystical piety thus has a bearing on the entire cosmos. The central concept is not the righteousness but the love of God. Thus, a different overall development of religious perception took place in the East, especially noticeable in the conception and development of the sacrament of penance. Since, in the East, the idea of educating the Christian to a life of sanctification is decisive, the juridical conception of penance never gained wide acceptance, and neither the doctrine nor the practice of indulgences was developed in the Eastern Church.

Motifs of the Eastern churches

Also, the Eastern Church did not claim power to intervene in the realm of the dead, to loosen or to bind. Eastern Christianity is familiar only with intercession for the dead, because the bond of the faithful who are joined together into the body of Christ is not extinguished even with death.

The legal idea is, however, present in the Eastern Church's view of the ecclesiastical office, especially in its conception of the episcopal office and apostolic succession. But the Eastern view is embedded in the conception of the church as the mystical body of Christ and of the Holy Spirit as the stream of life of the church. The bishops of the Eastern Orthodox Church have always remained primarily bishops (and not also temporal rulers) of their church and have always preserved the spiritual character of their office—even at the times when the churches were under Islāmic rule and the bishops were assigned the function of ethnarchs (official quasi-political representatives of the Christian portions of the population). The conception that the Orthodox priest has of the essence of his priesthood is, then, not determined through a judicial idea, and in the Orthodox sacrament of penance the formula of absolution has the form not of a declaration but of a prayer for divine forgiveness.

Judicial features are also absent from the Eastern Church's conception of human sanctification and, thereby, of the task of monasticism. In Eastern monasticism, a doctrine of good works or of the treasury of the church was never able to arise. Saints were venerated as spiritually gifted personalities who realized in this earthly life the angelic life of the heavenly church.

In Orthodox theology the schema of justification has scarcely played a role. Its chief motif is the incarnation of God and the idea that humans partake of aspects of deity. Though the term must be used cautiously, to avoid idolatry of the created human, it is not entirely inappropriate to speak of the "deification" of the human. Thus, the emphasis of Christian proclamation lay upon rebirth, the new creation of the human being, the process of transformation into a new creature, resurrection with Christ, and the ascension of humans to God, along with other changes properly called transfigurations. Only the penetration of Reformation ideas in the 16th and 17th centuries compelled Orthodox theologians to take a position on the doctrine of justification.

The incarnation of God and the deification of humans

In Roman thought sin is a violation of the legal relationship fixed by God between himself and man. Sin for the Eastern Church, however, is viewed as a narrowing of possibilities, or a contraction of essence, a sickness or infection of the original being of the image of God. Accordingly, redemption is not primarily the restoration of a judicial relationship disturbed by sin but rather a renewal of being, transfiguration of being, completion of being, and deification.

Thus, the idea of love is dominant in Eastern piety. Characteristic of this is a catechetical sermon by John Chrysostom, patriarch of Constantinople, about Christ's parable of the workers in the vineyard as told in Matthew, chapter 20. Still read at Easter in the 20th century from all pulpits of the Orthodox Church, the sermon is a song of triumph about the victory of the boundless love of God:

> You who have fasted and you who have not fasted, rejoice today! The table is laden, enjoy it everyone! The calf is fattened, may no one leave hungry! Everyone partake of the banquet of faith! Everyone partake of the riches of goodness! May no one complain of poverty, for the common Kingdom has appeared.

The conception of the Last Judgment in the Eastern Church did not develop according to the strictly juridical interpretation that was customary in the West. On the contrary, trust in grace and in the "love of man" by the divine Logos, as well as supplication for divine compassion, are dominant. Hence, the Orthodox Church understood only with difficulty the theological concern of the Western Reformation. It comprehended the Western Reformation only to the extent that it concurred with the latter in its rejection of certain Roman Catholic doctrines and practices—*e.g.*, the doctrine of papal primacy and the demand of priestly celibacy. The central argument about justification was reflected upon by only a few Orthodox theologians educated in the West, such as Cyril Lucaris, and in general the Eastern Church has withstood efforts to graft justification onto Orthodoxy.

GOD THE FATHER

On the basis of their religious experiences, the mystics of Christianity of all eras have concurred in the belief that one can make no assertions about God, because God is beyond all concepts and images. Inasmuch as human beings are gifted with reason, however, the religious experience of transcendence demands historical clarification. Thus, in Christian theology two tendencies stand in constant tension with each other. On the one hand, there is the tendency to systematize the idea of God as far as possible. On the other, there is the tendency to eliminate the accumulated collection of current conceptions of God and to return to the understanding of the utter transcendence of God. Theologians, by and large, have had to acknowledge the limits of human reason and language to address the "character" of God, who is beyond normal human experience but who impinges on it. But because of the divine–human contact, it became necessary and possible for them to make some assertions about the experience, the disclosure, and the character of God.

Tendencies within Christian theology to make assertions about God

All great epochs of the history of Christianity are defined by new forms of the experience of God and of Christ. Rudolf Otto, a 20th-century German theologian, attempted to describe to some extent the basic ways of

experiencing the transcendence of the "holy." He called these the experience of the "numinous" (the spiritual dimension), the utterly ineffable, the holy, and the overwhelming. The "holy" is manifested in a double form: as the *mysterium tremendum* ("mystery that repels"), in which the dreadful, fearful, and overwhelming aspect of the numinous appears, and as the *mysterium fascinosum* ("mystery that attracts"), by which humans are irresistibly drawn to the glory, beauty, adorable quality, and the blessing, redeeming, and salvation-bringing power of transcendence. All of these features are present in the Christian concepts of God as explicated in the ever new experiences of the charismatic leaders.

Characteristic features of the Christian concept of God. Within the Christian perception and experience of God, definite characteristic features stand out: (1) the personality of God, (2) God as the Creator, (3) God as the Lord of history, and (4) God as Judge. (1) God, as person, is the "I am who I am" designated in Exodus 3:14. The personal consciousness of human beings awakens in the encounter with God understood as a person: "The Lord used to speak to Moses face to face, as a man speaks to his friend" (Exodus 33:11). (2) God is also viewed as the Creator of heaven and Earth. The believer thus maintains, on the one hand, acknowledgement of divine omnipotence as the creative power of God, which also operates in the preservation of the world, and, on the other hand, trusts in the world, which—despite all its contradictions—is understood as one world created by God according to definite laws and principles and according to an inner plan. The decisive aspect of creation, however, is that God fashioned humans according to the divine image and made the creation subject to them. This special position of humans in the creation, which makes them coworkers of God in the preservation and consummation of the creation, brings a decisively new characteristic into the understanding of God. (3) This new characteristic is God as the Lord of history, which is the main feature of the Old Testament understanding of God: God selects a special people and contracts a special covenant with them. Through the Law the divine agent binds this "people of God" in a special way. God sets before them a definite goal of salvation—the establishment of a divine dominion—and through the prophets admonishes the people by proclamations of salvation and calamity whenever they are unfaithful to the covenant and promise. (4) This God of history also is the God of judgment. The genuinely Israelite belief that the disclosure of God comes through the history of divinely-led people leads, with an inner logic, to the proclamation of God as the Lord of world history and as the Judge of the world.

The special position of humans in creation and history

The specific concept of God as Father. What is decisively new in the Christian, New Testament faith in God lies in the fact that this faith is so closely bound up with the person, teaching, and work of Jesus Christ that it is difficult to draw boundaries between theology (doctrines of God) and Christology (doctrines of Christ). Jesus himself embraced the God of the Hebrew patriarchs (Abraham, Isaac, and Jacob), but he also understood himself as the fulfiller of the promise of the Messiah–Son of man, who is the bringer of the Kingdom of God. The religious experience that forms the basis of the messianic self-understanding of Jesus is the recognition that the Messiah–Son of man is the Son of God.

The special relationship of Jesus to God is expressed through his designation of God as Father. In prayers Jesus used the Aramaic word *abba* (father) for God, which is otherwise unusual in religious discourse in Judaism; it was usually employed by children for their earthly father, similar to "daddy" in English. This father–son relationship became a prototype for the relationship of Christians to God. Appeal to the sonship of God played a crucial role in the development of Jesus' messianic self-understanding. According to the account of Jesus' baptism, Jesus understood his sonship when a voice from heaven said: "This is my beloved Son, with whom I am well pleased." In the Gospel According to John, this sonship constitutes the basis for the self-consciousness of Jesus: "I and the Father are one" (John 10:30).

The special relationship of Jesus to God

The belief in the oneness of the Father and the Son. Faith in the Son also brought about a oneness with the Father. The Son became the mediator of the glory of the Father to those who believe in him. In Jesus' high priestly prayer (in John, chapter 17) he says: "The glory which thou hast given me I have given to them, that they may be one even as we are one, I in them and thou in me, that they may become perfectly one." In the Lord's Prayer Jesus taught his disciples to address God as "our Father."

The Father–God of Jesus after Jesus' death and Resurrection becomes—for his disciples—the God and Father of our Lord Jesus Christ (*e.g.,* 2 Corinthians 1:3), who revealed his love through the sacrifice of his Son who was sent into the world. Faithful Christians can thus become the children of God, as noted in Revelation 21:7: "I will be his God and he shall be my son." For Christians, therefore, faith in God is not a doctrine to be detached from the person of Jesus Christ.

Medieval theologians often spoke of a "Beatific Vision," a blessed vision of God. They did so on the basis of their own mystical experience that constituted the fulfillment of salvation in the Kingdom of God, which the Son will deliver to the Father.

In the history of Christian mysticism, this visionary experience of the transpersonal "Godhead" behind the personal "God" (as in the works of the medieval mystic Meister Eckhart)—also called an experience of the "trans-deity," the "divine ground," "groundlessness," the "abyss," and the divine "nothingness"—constantly breaks through and is renewed. Occasionally, this experience of transpersonal divine transcendence has directed itself against the development of a piety that has banalized the personal idea of God so much so that the glory and holiness of God has been trivialized. The attempt of the 20th-century theologian Paul Tillich to reduce the Christian idea of God to the impersonal concept of "the Ground of Being," or "Being Itself," pointed toward an understanding of the prepersonal depths of the transcendence of Godhood.

Transpersonal mystical and monoChristological tendencies

Nevertheless, in the Christian understanding of Christ as being one with the Father, there is a constant possibility that faith in God will be absorbed in a "monochristism"—*i.e.,* that the figure of the Son in the life of faith will overshadow the figure of the Father and thus cause it to disappear and that the figure of the Creator and Sustainer of the world will recede behind the figure of the Redeemer. The history of Christian piety and of Christian theology has constantly moved in this field of tension. Thus, the primacy of Christology and of the doctrine of justification in Reformation theology led to a depreciation of the creation doctrine and a Christian cosmology. This depreciation accelerated the estrangement between theology and the sciences during the period of the Enlightenment. This was subsequently distorted into a form of materialism. On the other hand, some 20th-century dialectical theologians, among them Karl Barth, in opposing materialism and humanism sometimes evoked a monochristic character that strongly accented the centrality of Christ at the expense of some cultural ties.

The revelatory character of God. The God of the Bible is the God who presses toward revelation. The creation of the world is viewed as an expression of God's will toward self-revelation, for even the pagans "knew God." In Paul's so-called Areopagus speech in Athens, he said of God: "Yet he is not far from each one of us, for 'in him we live and move and have our being,' " in allusion to the words of the pagan writer Aratus: "For we are indeed his offspring" (Acts 17:27–28). This was the beginning of a knowledge of God that has manifested itself under the catchphrase of the "natural revelation" of God or God's revelation in the "book of nature." It has survived as one strand of theory throughout much of Christian history.

God's bent toward self-revelation

The self-revelation of God presupposes, however, a basic biblical understanding of the existing relationship between God and human beings. It cannot be separated from the view that God created humans according to the divine image and that in Jesus Christ, who "reflects the glory of God and bears the very stamp of his nature" (Hebrews 1:3), the heavenly man has appeared among humans as the "last Adam." The inner connection between the "nat-

ural" and the biblical revelation takes place through the view of Christ as the divine Logos become human.

The tension between monotheism and the Logos doctrine

Hellenistic thinkers had already been attracted by the emphasis in later Judaism on monotheism and transcendence. This tendency was sketched out earlier in Plato and later Stoicism, but it came to its mature development in Neoplatonism in the 3rd century AD. In the 1st century Philo of Alexandria had interpreted the Old Testament concept of God in terms of the Logos idea of Hellenistic philosophy, but this Hellenization led to a characteristic tension that was to dominate the entire further history of Christian piety, as well as the Western history of ideas. The Greeks traced the idea of God to a "first cause" that stood behind all other causes and effects. Theologians under their influence used this understanding to contribute to a doctrine of God as "first cause" in Christian theology.

God as Creator, Sustainer, and Judge. The biblical understanding of God, however, was based upon the idea of the freedom of the Creator, Sustainer, and Judge vis-à-vis the world. This idea also included the concept that God could suspend the natural order or break the causal chain through miracles. This led to two specific problems that theology, inspired by Greek philosophy, set for itself: (1) the attempt to prove the existence of God, and (2) the attempt to justify God in view of both the apparent shortcomings of the creation and the existence of evil in history (*i.e.,* the problem of theodicy). Both attempts have occupied the intellectual efforts of Western theology and have inspired the highest of intellectual achievements. These attempts, however, often presumed that human reason could capture and define the transcendent. Even by the speculative theologians' definition such an effort was inherently impossible to conclude. Although such theologians creatively addressed the issue, it was often simple Christian piety that served to guard the notion of transcendence, while concentrating on the historical revelation of God in the more accessible instrument of God's self-disclosure in Jesus Christ.

Efforts to explain the ways of God to humans, particularly in respect to the problem of the existence of evil, are called theodicy. This form of justification of God has addressed profound human impulses and has relied upon strenuous exercises of human reason, but it has also led to no finally satisfying conclusions. The problem, which was already posed by Augustine and treated in detail by Thomas Aquinas, became of pressing importance in the European Thirty Years' War (1618–48) and its aftermath. At that time Gottfried Wilhelm Leibniz, who did more than anyone to develop the concept of theodicy, endeavoured to defend the Christian notion of God against the obvious atheistic consequences that were evoked by the critical thinkers of his time. This was because of the behaviour of the Christian churches, which were engaged in a war of mutual extermination. The result of such theological efforts, however, was either to declare God himself as the originator of evil, to excuse evil as a consequence of divine "permission," or instead—as with Hegel—to understand world history as the justification of God ("the true theodicy, the justification of God in history"). These answers satisfied neither the Christian experience of faith nor thoughtful reflection. Literature is full of examples in which writers influenced by the Christian tradition react against such justifications. One example can be found in the Russian novelist Fyodor Dostoyevsky's treatment of the suffering of children in *The Brothers Karamazov.*

The German philosopher Immanuel Kant set the terms for much modern reflection on God's existence when he challenged the grounds of most previous efforts to prove it. Kant contended that it was finally impossible for the human intellect to achieve insights into the realm of the transcendent. Even as he was arguing this, modern science was shifting from grounds that presumed the nature of God and God's universe to autonomous views of nature that were grounded only in experiment, skepticism, and research. During the 19th century, philosophers in Kantian and scientific traditions despaired of the attempt to prove the existence of God.

Modern attempts to abandon the idea of God

During the same period some Western intellectuals turned against the very idea of God. One strand of Hegelian thinkers, typified by the German philosopher Ludwig Feuerbach, attempted to unmask the idea of religion as illusion. To Feuerbach, faith was an ideology designed to help humans delude themselves. The idea of dialectical materialism, in which the concept of "spirit" was dropped by thinkers such as Karl Marx, developed in this tradition. It also characterized religion as "bad faith" or "the opiate of the people," designed to seduce them from efforts to build a good society through the hope of rewards in a life to come.

At the same time, at first chiefly in Britain, scientific thinkers in the tradition of Charles Darwin hypothesized that evolutionary processes denied all biblical concepts of divine creation. Some dialectical materialists incorporated Darwinian theories in a frontal attack on the Christian worldview. Some Christians contended that this was a perversion of evolution, since certain Christian teachings on divine creation, such as *creatio continua* ("continuing creation"), were both biblical and compatible with evolutionary theory. At the turn of the 20th century, some thinkers in both Britain and the United States optimistically reworked their doctrine of God in congruence with evolutionary thought.

Modern views of God. If 18th- and 19th-century rationalism and scientific attacks on the idea of God were often called "the first Enlightenment" or "the first illumination," in the 20th century a set of trends appeared that represented, to a broader public, a "second illumination." This included a rescue of the idea of God, even if it was not always compatible with previous Christian interpretations. Notable scientists of the 20th century, such as Albert Einstein, Max Planck, Max Born, and others, have on occasion, and against the testimony of the majority of their colleagues, allowed for an idea of God or religion in their concepts of life, the universe, and human beings.

Resurgence of a recognition of God

Corresponding to recognition of the idea of God by some leading scientific thinkers, there has been a new surge of experience of God noticeable in the different revival movements in the churches of Asia and Africa, as well as in America and Eurasia—in the midst of people either de-Christianized or attached to a purely conventional "cultural Christianity."

When the German philosopher Friedrich Nietzsche prophesied what he called "the death of God," many Christian thinkers agreed that a certain set of culturally conditioned and dogmatic concepts of God were inaccessible, implausible, and dying out. Some of these apologists argued that such a "death of God" was salutary, because it made room for a "God beyond the gods" of argument, or a "greater God." The French Jesuit thinker Pierre Teilhard de Chardin for a time attracted a large following as he set out to graft the theory of evolution onto "greater God" proclamations.

Certainly new understandings of physics, astronomy, and cosmology made it more difficult to defend pictures of God based upon notions of a small and young universe. The public grasped the change as it received images of a small Earth transmitted from space by Soviet and U.S. astronauts. Yet space exploration also inspired the imagination and led Christian thinkers who had positive views of science to use the occasion to enlarge the understanding of God and relate it to the Christian system.

The view that God is not solitary. The leaders of an 18th-century movement called Deism saw God as impersonal and unempathic—a principle of order and agent of responsibility not personal or addressable as the Christian God had been. Deism contributed to some intellectualizations of the idea of God, approaches that had sometimes appeared in the more sterile forms of medieval Scholasticism. God appeared to have been withdrawn from creation, which was pictured as a world machine; this God, at best, observed its running but never interfered.

According to the original Christian understanding of God of the early church, the Middle Ages, and the Reformers, God neither is solitary nor wishes to be alone. Instead, God is encircled with a boundless realm of angels, created in the divine image. They surround God in freely expressed love and devotion. They appear in a graduated, individuated hierarchy. These ranks of angels offer God

The role of angels

their praise, and they appear active in the universe as messengers and executors of the divine will. From the beginning God appears as the ruler and centre in this divinely fashioned realm, and the first created of this realm are the angels. The church of the angels is the upper church; the earthly church joins with them in the "cherubic hymn," the Trisagion ("Holy, Holy, Holy"), at the epiphany of the Lord and the angelic choirs surrounding him in the Eucharist. The earthly church is thus viewed as a participant—co-liturgist—in the angelic liturgy. Because the angels are created as free spiritual beings in accordance with the image of God, the first fall takes place in their midst—the first misuse of freedom was in the rebellion of the highest prince of the angels, Lucifer ("Light-bearer"), against God.

According to the view of the Fathers of the early church, teachers of the Middle Ages, and the Reformers, humans are only the second-created. The creation of human beings serves to refill the Kingdom of God with new spiritual creatures who are capable of offering to God the free love that the rebellious angels have refused to continue. In the realm of the first-created creatures, there already commences the problem of evil, which appears immediately in the freedom or misuse of freedom.

Satan and the origin of evil. In the Old and New Testaments, Satan (the devil) appears as the representative of evil. The philosophy and theology of the Enlightenment endeavoured to push the figure of the devil out of Christian consciousness as being a product of the mythological fantasy of the Middle Ages. It is precisely in this figure, however, that some aspects of the ways God deals with evil are especially evident. The devil first appears as an independent figure alongside God in the course of the Old Testament history of religion. In the Old Testament evil is still brought into a direct relationship with God; even evil, insofar as it has power and life, is effected by God: "I form light and create darkness, I make weal and create woe, I am the Lord, who do all these things" (Isaiah 45:7).

Satan gives expression to the demonic side of the divine wrath. In the Book of Job he appears as the partner of God, who on behalf of God puts the righteous one to the test. Only in postbiblical Judaism does the devil become the adversary of God, the prince of angels, who, created by God and placed at the head of the angelic hosts, entices some of the angels into revolt against God. In punishment for his rebellion he is cast from heaven together with his mutinous entourage, which were transformed into demons. As ruler over the fallen angels he henceforth continues the struggle against the Kingdom of God in three ways: he seeks to seduce man into sin; he tries to disrupt God's plan for salvation; and he appears before God as slanderer and accuser of the saints, so as to reduce the number of those chosen for the Kingdom of God.

Satan leaves the presence of God to test God's faithful servant, Job. Engraving by William Blake, 1825, for an illustrated edition of *The Book of Job*.

The functions of Satan

Thus, Satan has a threefold function: he is a creature of God, who has his being and essence from God; he is the partner of God in the drama of the history of salvation; and he is the rival of God, who fights against God's plan of salvation. Through the influence of the dualistic thinking of Zoroastrian religion during the Babylonian Exile (586–538 BC) in Persia, Satan took on features of a countergod in late Judaism. In the writings of the Qumrān sects (who preserved the Dead Sea Scrolls), Belial, the "angel of darkness" and the "spirit of wickedness," appears as the adversary of the "prince of luminaries" and the "spirit of truth." The conclusion of the history of salvation is the eschatological battle of the prince of luminaries against Belial, which ends with judgment upon him, his angels, and people subject to him and ushers in the cessation of "worry, groaning, and wickedness" and the beginning of the rule of "truth."

In the New Testament the features of an anti-godly power are clearly prominent in the figures of the devil, Satan, Belial, and Beelzebub—the "enemy." He is the accuser, the evil one, the tempter, the old snake, the great dragon, the prince of this world, and the god of this world, who seeks to hinder the establishment of God's dominion through the life and suffering of Jesus Christ. Satan offers to give to Christ the riches of this world if Christ will acknowledge him as supreme lord. Thus, he is the real antagonist of the Messiah–Son of man, Christ, who is sent by God into the world to destroy the works of Satan.

He is lacking, however, the possibility of incarnation: he is left to rob others in order to procure for himself the appearance of personality and corporeality. As opposed to *philanthrōpia,* the love of man of Christ, who presents himself as an expiatory sacrifice for the sins of mankind out of love for it, Satan appears among early church teachers, such as Basil of Caesarea in the 4th century, as the *misanthrōpos,* the hater of humanity; vis-à-vis the bringer of heavenly beauty, he is the hater of beauty, the *misokalos.* With Gnosticism, dualistic features also penetrated the Christian sphere of intuitive vision. In the *Letter of Barnabas* (early 2nd century) Satan appeared as "the Black One"; according to the 2nd-century apologist Athenagoras he is "the one entrusted with the administration of matter and its forms of appearance," "the spirit hovering above matter." Under the influence of Gnosticism and Manichaeism (a syncretistic religion founded by Mani, a 3rd-century Persian prophet), there also followed—based on their dualistic aspects—the demonization of the entire realm of the sexual. This appears as the special temptational sphere of the devil; in sexual activity, the role of the instrument of diabolic enticement devolves upon woman. Manichaeistic and Gnostic tendencies remained as a permanent undercurrent in the church and determined, to a great extent, the understanding of sin and redemption. Satan remained the prototype of sin as the rebel who does not come to terms with fulfilling his godlikeness in love to his original image and Creator but instead desires equality with God and places love of self over love of God.

Gnostic and Manichaean elements in Christian concepts of angels and sin against God

Among the Fathers of the early church, the idea of Satan as the antagonist of Christ led to a mythical interpretation of the incarnation and disguise in the "form of a servant." Through this disguise the Son of God makes his heavenly origin unrecognizable to Satan. In some graphic, and almost comic, medieval depictions Christ appears as the "bait" cast before Satan, after which Satan grasps because he believes Christ to be an ordinary human being subject to his power. In the Middle Ages a further feature was added: the understanding of the devil as the "ape of God," who attempts to imitate God through spurious, malicious creations that he interpolates for, or opposes to, the divine creations.

In church history, the eras of the awakening of a new

Consciousness of sin against God and a renewed sense of evil

consciousness of sin are identical with those of a newly awakened sense for the presence of "evil"—as was the case with Augustine, Bernard of Clairvaux, Luther, Calvin, and Wesley. In the Christian historical consciousness the figure of Satan plays an important role, not least of all through the influence of the Revelation to John. The history of salvation is understood as the history of a continuous struggle between God and the demonic antagonist, who with constantly new means tries to thwart God's plan of salvation. The idea of the "stratagems of Satan," as developed by a 16th-century fortress engineer, Giacomo Aconcio, had its roots here: the history of the world is a constant attempt of Satan to disrupt the salvation events of God through ever new counter-events. This altercation constitutes the religious background of the drama of world history. Characteristic here is the impetus of acceleration already indicated in Revelation: blow and counterblow in the struggle taking place between God and Satan follow in ever shorter intervals; for the devil "knows that his time is short" (Revelation 12:12), and his power in heaven has already been laid low. On Earth the possibility of his efficacy is likewise limited by the return of the Lord. Hence, his attacks upon the elect of the Kingdom so increase in the last times that God is moved to curtail the days of the final affliction, for "if those days had not been shortened, no human being would be saved" (Matthew 24:22). Many of these features are retained in the philosophy of religion of German Idealism as well as in Russian philosophy of religion. According to the 20th-century Russian philosopher Nikolay Berdyayev, like the Germans Friedrich Schelling and Franz von Baader before him, the devil has no true personality and no genuine reality and, instead, is filled with an insatiable "hunger for reality," which he can attain by stealing reality from the people of whom he takes possession. Since the Enlightenment, Christian theologians who found the mythical pictures of Satan to be irrelevant, distorting, or confusing in Christian thought and experience have set out to demythologize this figure. Apologists such as the British literary figure C.S. Lewis and the Russian philosopher Vladimir Solovyov, however, have written cautionary words. They conceive that it would represent the devil's most cunning attempt at self-camouflage to be demythologized and that camouflage would be a certain new proof of his existence.

GOD THE SON

Dogmatic teachings about the figure of Jesus Christ go back to the spontaneous faith experiences of the original church. The faithful of the early church experienced and recognized the incarnate and resurrected Son of God in the person of Jesus. The disciples' testimony served as confirmation for them that Jesus really is the exalted Lord and Son of God, who sits at the right hand of the Father and will return in glory to consummate the Kingdom.

Different interpretations of the person of Jesus. From the beginning of the church different interpretations of the person of Jesus have existed alongside one another. The Gospel According to Mark, for example, understands Jesus as the man upon whom the Holy Spirit descends at the baptism in the Jordan and who is declared the Son of God through the voice of God from the clouds. Two schools of thought developed—one associated with Antioch in Syria and the other with Alexandria in Egypt. Attempts at Christology that derive from the theological school of Antioch have followed one line of interpretation: they proceed from the humanity of Jesus and view his divinity in his consciousness of God, founded in the divine mission that was imposed upon him by God through the infusion of the Holy Spirit.

Another view was adopted by the catechetical school of Alexandrian theology. This view is expressed by the Gospel According to John, which regards the figure of Jesus Christ as the divine Logos become flesh. Here, the divinity of the person of Jesus is understood not as the endowment of the man Jesus with a divine power but rather as the result of the descent of the divine Logos—a preexistent heavenly being—into the world: the Logos taking on a human body of flesh so as to be realized in history. Thus it was that the struggle to understand the figures of Jesus Christ created a rivalry between the theologies of Antioch and Alexandria. Both schools had a wide sphere of influence, not only among the contemporary clergy but also in monasticism and among the laity. Characteristically, Nestorianism (a heresy founded in the 5th century), with its strong emphasis upon the human aspects of Jesus Christ, arose from the Antiochene school, whereas Monophysitism (a heresy founded in the 5th century), with its one-sided stress upon the divine nature of Christ, emerged from the Alexandrian school of theology.

Emphasis on the Logos

The Christological controversies. New intermediate solutions for resolving the Christological problem constantly were proposed between the two extreme positions of Antioch and Alexandria. As in the area of the doctrine of the Trinity, the general development of Christology has been characterized by a plurality of views and formulations. Also, the creeds of the major churches have by no means agreed with each other word for word. After Constantine, the great ecumenical synods occupied themselves essentially with the task of creating uniform formulations binding upon the entire imperial church.

Even the Christological formulas, however, do not claim to offer a rational, conceptual clarification; instead, they emphasize clearly three contentions in the mystery of the sonship of God. These are: first, that Jesus Christ, the Son of God, is completely God, that in reality "the whole fullness of deity dwells bodily" in him (Colossians 2:9); second, that he is completely human; and third, that these two "natures" do not exist beside one another in an unconnected way but, rather, are joined in him in a personal unity. Once again, the Neoplatonic metaphysics of substance offered the categories so as to settle conceptually these various theological concerns. Thus, the idea of the unity of essence (*homoousia*) of the divine Logos with God the Father assured the complete divinity of Jesus Christ, and the mystery of the person of Jesus Christ could be grasped in a complex but decisive formula: two natures in one person. The concept of person, taken from Roman law, served to join the fully divine and fully human natures of Christ into an individual unity. Christology is not the product of abstract, logical operations but instead originates in the liturgical and charismatic sphere wherein Christians engage in prayer, meditation, and asceticism. Not being derived primarily from abstract teaching, it rather changes within the liturgy in new forms and in countless hymns of worship—as in the words of the Easter liturgy:

Christology as originating in the charismatic sphere

> The king of the heavens appeared on earth out of kindness to man and it was with men that he associated. For he took his flesh from a pure virgin and he came forth from her, in that he accepted it. One is the Son, two-fold in essence, but not in person. Therefore in announcing him as in truth perfect God and perfect man, we confess Christ our God.

Messianic views. Faith in Jesus Christ is related in the closest way to faith in the Kingdom of God, the coming of which he proclaimed and introduced. Christian eschatological expectations, for their part, were joined with the messianic promises, which underwent a decisive transformation and differentiation in late Judaism, especially in the two centuries just before the appearance of Jesus. Two basic types can be distinguished as influencing the messianic self-understanding of Jesus as well as the faith of his disciples.

The old Jewish view of the fulfillment of the history of salvation was guided by the idea that at the end of the history of the Jewish people the Messiah will come from the house of David and establish the Kingdom of God—an earthly kingdom in which the Anointed of the Lord will gather the tribes of the chosen people and from Jerusalem will establish a world kingdom of peace. Accordingly, the expectation of the Kingdom had an explicitly inner-worldly character. The expectation of an earthly Messiah as the founder of a Jewish kingdom became the strongest impulse for political revolutions, primarily against Hellenistic and Roman dominion. The period preceding the appearance of Jesus was filled with continuous new messianic uprisings in which new messianic personalities appeared and claimed for themselves and their struggles for liberation the miraculous powers of the Kingdom of God. Especially

in Galilee, guerrilla groups were formed in which hope for a better future blazed all the more fiercely, because the present was so unpromising. Jesus disappointed the political expectations of these popular circles; he did not let himself be made a political Messiah. Conversely, it was his opponents who used the political misinterpretation of his person to destroy him. Jesus was condemned and executed by the responsible Roman authorities as a Jewish rioter who rebelled against Roman sovereignty. The inscription on the cross, "Jesus of Nazareth, king of the Jews," cited the motif of political insurrection of a Jewish messianic king against the Roman government as the official reason for his condemnation and execution.

Alongside this political type of messianic expectation there was a second form of eschatological expectation. Its supporters were the pious groups in the country, the Essenes and the Qumrān community on the Dead Sea. Their yearning was directed not toward an earthly Messiah but toward a heavenly anointed one, who would bring not an earthly but a heavenly kingdom. Fulfillment lay not in the old world but in the future, coming world, for which the main thing was to prepare oneself through repentance. These pious ones wanted to know nothing of sword and struggle, uprising and rebellion. They believed that the wondrous power of God alone would create the new time. The birth of a new eon would be preceded by intense messianic woes and a frightful judgment upon the godless, the pagan peoples, and Satan with his demonic powers. The Messiah would come not as an earthly king from the house of David but as a heavenly figure, as the Son of God, a heavenly being of the ages, who would descend into the world of the Evil One and there gather his own to lead them back into the realm of light. He would take up dominion of the world and, after overcoming all earthly and supernatural demonic powers, lay the entire cosmos at the feet of God.

Hope for a future world

A second new feature, anticipation of the Resurrection, was coupled with this transcending of the old expectation. According to the old Jewish eschatological expectation, the beneficiaries of the divine development of the world would be only the members of the last generation of humanity who were fortunate enough to experience the arrival of the Messiah upon Earth; all earlier generations would be consumed with the longing for fulfillment but would die without experiencing it. Ancient Judaism knew no hope of resurrection. In connection with the transcending of the expectation of the Kingdom of God, however, even anticipations of resurrection voiced earlier by Zoroastrianism were achieved: the Kingdom of God was to include within itself in the state of resurrection all the faithful of every generation of humanity. Even the faithful of the earlier generations would find in resurrection the realization of their faith. In the new eon the Messiah–Son of man would rule over the resurrected faithful of all times and all peoples. A characteristic breaking free of the eschatological expectation was thereby presented. It no longer referred exclusively to the Jews alone; with its transcendence a universalistic feature entered into it.

Jesus—in contrast to John the Baptist (a preacher of repentance who pointed to the coming bringer of the Kingdom)—knew himself to be the one who brought fulfillment of the Kingdom itself, because the wondrous powers of the Kingdom of God were already at work in him. He proclaimed the glad news that the long promised Kingdom was already dawning, that the consummation was here. This is what was new: the promised Kingdom, supra-worldly, of the future, the coming new eon, already reached redeemingly into the this-worldly from its beyondness, as a charismatic reality that brought people together in a new community.

Jesus as the Son of man

Jesus did not simply transfer to himself the promise of heavenly Son of man, as it was articulated in the apocryphal First Book of Enoch. Instead, he gave this expectation of the Son of man an entirely new interpretation. Pious Jewish circles, such as the Enoch community and other pietist groups, expected in the coming Son of man a figure of light from on high, a heavenly conquering hero, with all the marks of divine power and glory. Jesus, however, linked expectations of the Son of man with the figure of the suffering servant of God (as in Isaiah, chapter 53). He would return in glory as the consummator of the Kingdom. This self-understanding of Jesus was compatible with Christologies derived from the concept of the divine Logos.

The doctrine of the Virgin Mary and holy Wisdom. The dogma of the Virgin Mary as the "mother of God" and "bearer of God" is connected in the closest way with the dogma of the incarnation of the divine Logos. The theoretical formation of doctrine did not bring the cult of the mother of God along in its train; instead, the doctrine only reflected the unusually great role that the veneration of the mother of God already had taken on at an early date in the liturgy and in the church piety of Orthodox faithful.

The expansion of the veneration of the Virgin Mary as the bearer of God (Theotokos) and the formation of the corresponding dogma is one of the most astonishing occurrences in the history of the early church. The New Testament offers only scanty points of departure for this development. Mary completely recedes behind the figure of Jesus Christ, who stands in the centre of all four Gospels. From the Gospels themselves it can be recognized that Jesus' development into the preacher of the Kingdom of God took place in sharp opposition to his family, who were so little convinced of his mission that they held him to be insane (Mark 3:21). Accordingly, all the Gospels stress the fact that Jesus separated himself from his family. Even the Gospel According to John still preserved traces of Jesus' tense relationship with his mother. Mary appears twice without being called by name the mother of Jesus; and Jesus himself regularly withholds from her the designation of mother. The saying, "Woman, what have you to do with me?" (John 2:4), is indeed the strongest expression of a conscious distancing.

The opposition of Jesus' family toward him

Nevertheless, with the conception of Jesus Christ as the Son of God, a tendency developed early in the church to grant to the mother of the Son of God a special place within the church. This development was sketched quite hesitantly in the New Testament. Only the prehistories in Matthew and Luke mention the virgin birth, which, however, cannot be simply coordinated or reconciled with the statements of the preceding genealogical tables. On these scanty presuppositions the later cult of the mother

of God was developed. The view of the virgin birth entered into the creed of all Christianity and became one of the strongest religious impulses in the development of the dogma, liturgy, and ecclesiastical piety of the early church.

Veneration of the mother of God received its impetus when the Christian Church became the imperial church under Constantine and the pagan masses came under Christian influences and became members of the church. The peoples of the Mediterranean area and the Middle East could not make themselves conversant with the absolute power of God the Father and with the strict patriarchalism of the Jewish idea of God, which the original Christian message had taken over. Their piety and religious consciousness had been formed for millennia through the cult of the "great mother" goddess and the "divine virgin," a development that led all the way from the old popular religions of Babylonia and Assyria to the mystery cults of the late Hellenistic period. Despite the unfavourable presuppositions in the tradition of the Gospels, cultic veneration of the divine virgin and mother found within the Christian Church a new possibility of expression in the worship of Mary as the virgin mother of God, in whom was achieved the mysterious union of the divine Logos with human nature. The spontaneous impulse of popular piety, which pushed in this direction, moved far in advance of the practice and doctrine of the church. In Egypt, Mary was, at an early point, already worshiped under the title of Theotokos—an expression that Origen used in the 3rd century. The Council of Ephesus (431) raised this designation to a dogmatic standard. To the latter, the second Council of Constantinople (553) added the title "eternal Virgin." In the prayers and hymns of the Orthodox Church the name of the mother of God is invoked as often as is the name of Christ and the Holy Trinity.

Absorption of the cult of the "great mother"

The doctrine of the heavenly Wisdom (Sophia) represents an Eastern Church particularity. In late Judaism, speculations about the heavenly Wisdom—a heavenly figure beside God that presents itself to humanity as mediator in the work of creation as well as mediator of the knowledge of God—abounded. In Roman Catholic doctrine, Mary, the mother of God, was identified with the figure of the divine Wisdom. To borrow a term used in Christology to describe Jesus as being of the same substance (hypostasis) as the Father, Mary was seen as possessing a divine hypostasis.

Mary and heavenly Wisdom

This process of treating Mary and the heavenly Wisdom alike did not take place in the realm of the Eastern Orthodox Church. For all its veneration of the mother of God, the Eastern Orthodox Church never forgot that the root of this veneration lay in the incarnation of the divine Logos that took place through her. Accordingly, in the tradition of Orthodox theology, a specific doctrine of the heavenly Wisdom, Sophianism, is found alongside the doctrine of the mother of God. This distinction between the mother of God and the heavenly Sophia in 20th-century Russian philosophy of religion (in the works of Vladimir Solovyov, Pavel Florensky, W.N. Iljin, and Sergey Bulgakov) developed a special Sophianism. Sophianism did, however, evoke the opposition of Orthodox academic theology. The numerous great churches of Hagia Sophia, foremost among them the cathedral by that name in Constantinople (Istanbul), are consecrated to this figure of the heavenly Wisdom.

GOD THE HOLY SPIRIT

Contradictory aspects of the Holy Spirit. The Holy Spirit of God becomes one of the most elusive and difficult themes in Christian theology, because it refers to one of the three Persons in the Godhead but does not evoke concrete images the way "Father" or "Creator" and "Son" or "Redeemer" do. Reference to the Holy Spirit includes the true creative element in the life of the church. It works in an apparently contradictory sense: by virtue of its authority, the Holy Spirit establishes law and breaks law, it institutes order and breaks order, it founds tradition and breaks tradition. It is the conservative as well as the revolutionary principle in church history. It guarantees the continuity of the church and yet it interrupts this continuity ever again through new creations. Both sides of this activity stand in a characteristic relationship of tension to one another.

The essence of free spontaneity

The essence of the expression of the Holy Spirit is free spontaneity. The Spirit blows like the wind, "where it wills," but where it blows it establishes a firm norm by virtue of its divine authority. The spirit of prophecy and the spirit of knowledge (*gnōsis*) are not subject to the will of the prophet and the enlightened one; revelation of the Spirit in the prophetic word or in the word of knowledge becomes Holy Scripture, which as "divinely breathed" "cannot be broken" and lays claim to a lasting validity for the church.

The Spirit, which is expressed in the various officeholders of the church, likewise founds the authority of ecclesiastical offices. The laying on of hands, as a sign of the transference of the Holy Spirit from one person to another, is a characteristic ritual that visibly represents and guarantees the continuity of the working of the Spirit in the officeholders chosen by the Apostles; it becomes the sacramental sign of the succession of the full power of spiritual authority of bishops and priests. The Holy Spirit also creates the sacraments and guarantees the constancy of their action in the church. All the expressions of church life—doctrine, office, polity, sacraments, power to loosen and to bind, and prayer—are understood as endowed by the Spirit.

The same Holy Spirit, however, also comes forth as the revolutionizing, freshly creating principle in church history. All the decisive reformational movements in church history, which broke with old institutions, have appealed to the authority of the Holy Spirit. This is probably the main reason that in the history of church dogma the article of the Holy Spirit has been developed only hesitantly and incompletely in comparison with the Christological article. A characteristic view of the Holy Spirit is sketched out in the Gospel According to John: the outpouring of the Holy Spirit takes place only after the Ascension of

Christ; it is the beginning of a new time of salvation, in which the Holy Spirit is sent as the Paraclete (Counsellor) to the church remaining behind in this world. The ecstatic phenomena, which are prominent in the church at Pentecost, are understood as fulfillment of this promise. With this event (Pentecost) the church entered into the period of the Holy Spirit. After a process of institutionalization in the church, opposition against it—through appeal to the Holy Spirit—became noticeable for the first time in Montanism, in the mid-2nd century. Montanus, a Phrygian prophet and charismatic leader, understood himself and the prophetic movement sustained by him as the fulfillment of the promise of the coming of the Paraclete. In the 13th century a spiritualistic countermovement against the feudalized institutional church gained attention anew in Joachim of Fiore, who understood the history of salvation in terms of a continuing self-realization of the divine Trinity in the three times of salvation: (1) the time of the Father, (2) the time of the Son, and (3) the time of the Holy Spirit. He promised the speedy beginning of the period of the Holy Spirit, in which the institutional papal church, with its sacraments and its revelation hardened in the letter of scripture, would be replaced by a community of charismatic figures, filled with the Spirit, and by the time of "spiritual knowledge." This promise became the spiritual stimulus of a series of revolutionary movements within the medieval church—*e.g.,* the reform movement of the radical Franciscan spirituals and the Hussite reform movement led by Jan Hus in 15th-century Bohemia. Their effects extend to a 16th-century radical reformer, Thomas Müntzer, who substantiated his revolution against the princes and clerical hierarchs with a new outpouring of the Spirit. Quakerism represents the most radical mode of rejection—carried out in the name of the freedom of the Holy Spirit—of all institutional forms, which are regarded as shackles and prisons of the Holy Spirit. In the 20th century a revival of charismatic forms of Christianity, called Pentecostalism and the charismatic movement, centred on the recovery of the experience of the Holy Spirit and necessitated some fresh theological inquiry about the subject.

Revolutionary movements appealing to the Holy Spirit

Conflict between order and charismatic freedom. As the fundamentally uncontrollable principle of life in the church, the Holy Spirit considerably upset Christian congregations from the very outset. Paul struggled to restrict the anarchist elements, which are connected with the appearance of free charismata (spiritual phenomena), and, over against these, to achieve a firm order in the church. Paul at times attempted to control and even repress charismatic activities, which he seemed to regard as irrational or prerational and thus potentially disruptive of fellowship. Among these were glossolalia, or speaking in tongues, a form of unrepressed speech. Paul preferred rational discourse in sermons. He also felt that spontaneity threatened the focus of worship. This tendency led to an emphasis on ecclesiastical offices with their limited authority vis-à-vis the uncontrolled appearance of free charismatic figures.

The conflict between church leadership resident in the locality and the appearance of free charismatic figures in the form of itinerant preachers forms the main motif of the oldest efforts for a church order. This difficulty became evident in the *Didachē,* the *Teaching of the Twelve Apostles* (early 2nd century). The authority of the Holy Spirit, in whose name the free charismatic figures speak, does not allow its instructions and prophecies to be criticized in terms of contents; its evaluation had to be made dependent upon purely ethical qualifications. This tension ended, in practical terms, with the exclusion of the free charismatic figures from the leadership of the church. The charismatic continuation of the revelation, in the form of new scriptures of revelation, was also checked. In the long historical process during which the Christian biblical canon took shape, Bishop Athanasius of Alexandria, in his 39th Easter letter (367), selected the number of writings—of apostolic origin—that he considered "canonical." Revelation in the form of Holy Scriptures binding for the Christian faith was thereby considered definitively concluded. The canon, henceforth fixed, can no longer be changed, abridged, or supplemented.

The fixing of revelation in a set number of sacred books

In a similar way, individual charismatic offices become institutionalized. A lower degree of consecration—a first stage for priestly ordination—still holds for the exorcist, the ritual figure who drives the devil from the possessed or those who are to be baptized. The teacher (*didaskalos*) also becomes institutionalized. In the Roman Church, only ordained priests are permitted to be church teachers—in contrast to the Eastern Orthodox Church, which until the 20th century did not require ecclesiastical ordination of a professor of theology.

The article about the Holy Spirit in the church creeds reflects little of these struggles. It suppresses the revolutionary principle of the Holy Spirit. Neither the so-called Apostles' Creed nor the Nicene Creed goes beyond establishment of faith in the Holy Spirit and its participation in the incarnation. In the Nicene Creed it is further emphasized that the Holy Spirit is the life-creating power—*i.e.,* the power both of creation and of rebirth—and that the Spirit has already spoken in the prophets.

The emergence of Trinitarian speculations in early church theology led to great difficulties in the article about the "person" of the Holy Spirit. In the New Testament the Holy Spirit tended to be present more as power than as person, though there was distinctive personal representation in the form of the dove at Jesus' baptism. But it was difficult to incorporate this graphic or symbolic representation into dogmatic theology. Nevertheless, with Athanasius the idea of the complete essence (*homoousia*) of the Holy Spirit with the Father and the Son was achieved. This was in opposition to all earlier attempts to subordinate the Holy Spirit to the Son and to the Father and to interpret the Spirit—similarly to anti-Trinitarian Christology—as a prince of the angels. According to Athanasius, the Holy Spirit alone guarantees the complete redemption of humanity: "through participation in the Holy Spirit we partake of the divine nature." In his work *De Trinitate,* Augustine undertook to render the essence of the Trinity understandable in terms of the Trinitarian structure of the human person: the Holy Spirit appears as the Spirit of love, which joins Father and Son and draws people into this communion of love. In Eastern Church theological thought, however, the Holy Spirit and the Son both proceed from the Father. In the West, the divine Trinity is determined more by the idea of the inner Trinitarian life in God; thus, the notion was carried through that the Holy Spirit goes forth from the Father and from the Son. Despite all the efforts of speculative theology, a graphic conception of the person of the Holy Spirit was not developed even later in the consciousness of the church.

The relationship of the Holy Spirit to the Father and the Son

The operations of the Holy Spirit. For the Christian faith, the Holy Spirit is clearly recognizable in charismatic figures (the saints), in whom the gifts of grace (charismata) of the Holy Spirit are expressed in different forms: reformers and other charismatic figures. The prophet, for instance, belongs to these charismatic types. The history of the church knows a continuous series of prophetic types, which reaches from New Testament prophets, such as Agabus (in Acts 11:28), through the 12th-century monk Bernard of Clairvaux to such Reformers as Luther and Calvin. Christoph Kotter and Nicolaus Drabicius—prophets of the Thirty Years' War period—were highly praised by the 17th-century Moravian bishop John Amos Comenius. Other prophets have existed in Pietism, Puritanism, and the Anglo-Saxon Free churches.

Prophetic women are especially numerous. In church history they begin with Anna (in Luke 2:36) and the prophetic daughters of the apostle Philip. Others are: Hildegard von Bingen, St. Bridget of Sweden, Joan of Arc, and the prophetic women of the Reformation period. In the modern world numbers of pioneers in the "holiness" and Pentecostal traditions were women, and women's gifts of prophecy have sometimes been cherished among Pentecostalists when they were overlooked or disdained by much of the rest of Christianity.

A further type of charismatic person is the healer, who functioned in the early church as an exorcist but who also emerged as a charismatic type in healing personalities of more recent church history (*e.g.,* Vincent de Paul in the 17th century). Equally significant is the curer-of-souls

Types of charismatic leaders

type, who exercises the gift of "distinguishing between spirits" in daily association with people. This gift is found especially emphasized among many of the great saints of all times. In the 19th century it particularly stands out in Johann Christoph Blumhardt, in Protestantism, and in Jean-Baptiste Vianney, the curé of Ars, in Roman Catholicism.

The charismatic wanderer type, who leads a roving life in imitation of Jesus Christ, who "has nowhere to lay his head," was molded through the ideal of "ascetic homelessness." The latter drove Scots-Irish monks, for example, not only through all of Europe but also to the remotest islands of the northern seas and as far as Iceland and Newfoundland. This ideal is still alive today in the Eastern Orthodox Church in the form of the *strannik* ("wanderer"). The "holy fool" type conceals a radical Christianity under the mask of foolishness and holds the truth of the gospel, in the disguise of folly, before the eyes of highly placed personalities: the worldly and the princes of the church who do not brook unmasked truth. This type, which frequently appeared in the Byzantine Church, has been represented especially in Western Christianity by Philip Neri, the founder of the religious order known as the Oratorians, in the 16th century.

The charismatic teacher (*didaskalos*), on the other hand, still appears. Filled with the spirit of intelligence or knowledge of the Holy Spirit, he carries out his teaching office, which does not necessarily need to be attached to an academic position. Many Free Church and ecclesiastical reform movements owe their genesis to such spirit-filled teachers, who are often decried as anomalous. The deacon likewise is originally the holder of a charismatic office of selfless service. Christian service, or *diakonia,* was not confined to Christian offices. Some of the energies that once went into it are now found in social service outside the church. Many of the agents of such service were originally or still may be inspired by Christian norms and examples in the care of the sick and the socially outcast or overlooked. Alongside such men as the Pietist August Hermann Francke, the Methodist John Wesley, Johann Wichern (the founder of the Inner Mission in Germany), and Friederich von Bodelschwingh (the founder of charitable institutions), important women have appeared as bearers of this charisma (*e.g.,* the English nurse Florence Nightingale and the Salvation Army leader Catherine Booth).

The Holy Spirit that "blows where it wills" has often been recognized as the impulse behind an enlargement of roles for women in the church. However limited these have been, they enlarged upon those that Christians inherited from Judaism. Partitions had screened women in a special left-hand section of the synagogue. While the pace of innovation was irregular, in the ecstatic worship services of the Christian congregations women tended to participate in speaking in tongues, hymns, prayer calls, or even prophecies. Evidently, this innovation in the face of the strict synagogal custom was held admissible on the basis of the authority of the Holy Spirit: "Do not quench the Spirit" (1 Thessalonians 5:19). Inasmuch as the appearance of charismatic women upset traditional concepts, however, Paul, acting on any number of personal and social motivations, reverted to the synagogal principle and inhibited the speaking role of women: "the women should keep silence in the churches." (1 Corinthians 14:34).

Because expressions of free charisma were increasingly suppressed in the institutional churches, the emergence of Pentecostal movements outside the institutional churches and partly in open opposition to them arose. This movement led to the founding of various Pentecostal Free churches at the end of the 19th century and the beginning of the 20th; today, it is represented through numerous independent Pentecostal groups, such as the Church of God and the Assemblies of God. At first scorned by the established churches and devalued as "demonic," the Pentecostal movement has grown to a world movement with strong missionary activity not only in Africa and South America but also in the European countries. In the United States, a strong influence of the Pentecostal movement—which has returned high esteem to the proto-Christian charismata of speaking in tongues, healing, and exorcism—is noticeable in the older churches as well, even in the Roman Catholic, Lutheran, and Anglican. This has occurred especially in liturgy and church music but also in preaching style and the return to faith healing.

THE HOLY TRINITY

The basis for the doctrine of the Trinity. The central Christian affirmations about God are condensed and focused in the classic doctrine of the Trinity, which has its ultimate foundation in the special religious experience of the Christians in the first communities. This basis of experience is older than the doctrine of the Trinity. It consisted of the fact that God came to meet Christians in a threefold figure: (1) as Creator, Lord of the history of salvation, Father, and Judge, as revealed in the Old Testament; (2) as the Lord who, in the figure of Jesus Christ, lived among human beings and was present in their midst as the "Resurrected One"; and (3) as the Holy Spirit, whom they experienced as the power of the new life, the miraculous potency of the Kingdom of God. The question as to how to reconcile the encounter with God in this threefold figure with faith in the oneness of God, which was the Jews' and Christians' characteristic mark of distinction from paganism, agitated the piety of ancient Christendom in the deepest way. In the course of history, it also provided the strongest impetus for a speculative theology, which inspired Western metaphysics for many centuries. In the first two centuries of the Christian Era, however, a series of different answers to this question stood in juxtaposition. At first none of the Christian theologians had considered them speculatively.

The revelation of God in three figures

The diversity in interpretation of the Trinity was conditioned especially through the understanding of the figure of Jesus Christ. According to the theology of the Gospel According to John, the *divinity* of Jesus Christ constituted the departure point for understanding his person and efficacy. The Gospel According to Mark, however, did not proceed from a theology of incarnation but instead understood the baptism of Jesus Christ as the adoption of the

Novosti Press Agency

Testament Trinity, detail from the Four-Part-Icon, Novgorod School, *c.* 1400. In the State Russian Museum, Leningrad.

man Jesus Christ into the Sonship of God, accomplished through the descent of the Holy Spirit. The situation became further aggravated by the conceptions of the special personal character of the manifestation of God developed by way of the historical figure of Jesus Christ; the Holy Spirit was viewed not as a personal figure but rather as a power and appeared graphically only in the form of the dove and thus receded, to a large extent, in the Trinitarian speculation.

Introduction of Neoplatonic themes. In the Johannine literature in the Bible there appeared the first traces of the concept of Christ as the Logos, the "word" or "principle" that issues from eternity. Under the influence of subsequent Neoplatonic philosophy, this tradition became central in speculative theology. There was interest in the relationship of the "oneness" of God to the "triplicity" of divine manifestations. This question was answered through the Neoplatonic metaphysics of being. The transcendent God, who is beyond all being, all rationality, and all conceptuality, is divested of divine transcendence. In a first act of becoming self-conscious the Logos recognizes itself as the divine mind (Greek: *nous*), or divine world reason, which was characterized by the Neoplatonic philosopher Plotinus as the "Son" who goes forth from the Father. The next step by which the transcendent God becomes self-conscious consists in the appearance in the divine *nous* of the divine world, the idea of the world in its individual forms as the content of the divine consciousness. In Neoplatonic philosophy both the *nous* and the idea of the world are designated the hypostases of the transcendent God. Christian theology took the Neoplatonic metaphysics of substance as well as its doctrine of hypostases as the departure point for interpreting the relationship of the "Father" to the "Son" in terms of the Neoplatonic hypostases doctrine. This process stands in direct relationship with a speculative interpretation of Christology in connection with Neoplatonic Logos speculation.

The assumption of the Neoplatonic hypostases doctrine meant from the beginning a certain evaluation of the relationships of the three divine figures to one another, because for Neoplatonism the process of hypostatization is at the same time a process that includes a diminishing of being. Thus, in flowing forth from the transcendent source, the divine being is progressively weakened with the distance from the transcendent origin. Diminution of being, on these terms, is brought about through approach to matter, which for its part is understood in Neoplatonism as nonbeing. In transferring the Neoplatonic hypostases doctrine to the Christian interpretation of the Trinity there existed the danger that the different manifestations of God—as known by the Christian experience of faith: Father, Son, Holy Spirit—would be transformed into a hierarchy of gods graduated among themselves and thus into a polytheism. Though this danger was consciously avoided and, proceeding from a Logos Christology, the complete sameness of essence of the three manifestations of God was emphasized, there arose the danger of a relapse into a triplicity of equally ranked gods, which would displace the idea of the oneness of God.

Attempts to define the Trinity. By the 3rd century it was already apparent that all attempts to systematize the mystery of the divine Trinity with the theories of Neoplatonic hypostases metaphysics were unsatisfying and led to a constant series of new conflicts. The high point, upon which the basic difficulties underwent their most forceful theological and ecclesiastically political actualization, was the so-called Arian controversy. Arius belonged to the Antiochene school of theology, which placed strong emphasis upon the historicity of the man Jesus Christ. In his theological interpretation of the idea of God, Arius was interested in maintaining a formal understanding of the oneness of God. In defense of the oneness of God, he was obliged to dispute the sameness of essence of the Son and the Holy Spirit with God the Father, as stressed by the theologians of the Neoplatonically influenced Alexandrian school. From the outset, the controversy between both parties took place upon the common basis of the Neoplatonic concept of substance, which was foreign to the New Testament itself. It is no wonder that the continuation of the dispute on the basis of the metaphysics of substance likewise led to concepts that have no foundation in the New Testament—such as the question of the sameness of essence (*homoousia*) or similarity of essence (*homoiousia*) of the divine persons.

Emphasis on the historicity of Jesus

The basic concern of Arius was and remained disputing the oneness of essence of the Son and the Holy Spirit with God the Father, in order to preserve the oneness of God. The Son, thus, became a "second God, under God the Father"—*i.e.*, he is God only in a figurative sense, for he belongs on the side of the creatures, even if at their highest summit. Here Arius joined an older tradition of Christology, which had already played a role in Rome in the early 2nd century—namely, the so-called angel-Christology. The descent of the Son to Earth was understood as the descent to Earth of the highest prince of the angels, who became man in Jesus Christ; he is to some extent identified with the angel prince Michael. In the old angel-Christology the concern is already expressed to preserve the oneness of God, the inviolable distinguishing mark of the Jewish and Christian faiths over against all paganism. The Son is not himself God, but as the highest of the created spiritual beings he is moved as close as possible to God. Arius joined this tradition with the same aim—*i.e.*, defending the idea of the oneness of the Christian concept of God against all reproaches that Christianity introduces a new, more sublime form of polytheism.

The angel-Christology of the 2nd century

This attempt to save the oneness of God led, however, to an awkward consequence. For Jesus Christ, as the divine Logos become human, moves thereby to the side of the creatures—*i.e.*, to the side of the created world that needs redemption. How, then, should such a Christ, himself a part of the creation, be able to achieve the redemption of the world? On the whole, the Christian Church rejected, as an unhappy attack upon the reality of redemption, such a formal attempt at saving the oneness of God as was undertaken by Arius.

The main speaker for church orthodoxy was Athanasius of Alexandria, for whom the point of departure was not a philosophical–speculative principle but rather the reality of redemption, the certainty of salvation. The redemption of humanity from sin and death is only then guaranteed if Christ is total God and total human being, if the complete essence of God penetrates human nature right into the deepest layer of its carnal corporeality. Only if God in the full meaning of divine essence became human in Jesus Christ is deification of man in terms of overcoming sin and death guaranteed as the resurrection of the flesh.

Augustine, of decisive importance for the Western development of the Trinitarian doctrine in theology and metaphysics, coupled the doctrine of the Trinity with anthropology. Proceeding from the idea that humans are created by God according to the divine image, he attempted to explain the mystery of the Trinity by uncovering traces of the Trinity in the human personality. He went from analysis of the Trinitarian structure of the simple act of cognition to ascertainment of the Trinitarian structure both of human self-consciousness and of the act of religious contemplation in which people recognize themselves as the image of God.

A second model of Trinitarian doctrine—suspected of heresy from the outset—which had effects not only in theology but also in the social metaphysics of the West as well, emanated from Joachim of Fiore. He understood the course of the history of salvation as the successive realization of the Father, the Son, and the Holy Spirit in three consecutive periods of salvation. This interpretation of the Trinity became effective as a "theology of revolution," inasmuch as it was regarded as the theological justification of the endeavour to accelerate the arrival of the third state of the Holy Spirit through revolutionary initiative.

The final dogmatic formulation of the Trinitarian doctrine in the so-called Athanasian Creed (*c.* 500), *una substantia—tres personae* ("one substance—three persons"), reached back to the formulation of Tertullian. In practical terms it meant a compromise in that it held fast to both basic ideas of Christian revelation—the oneness of God and divine self-revelation in the figures of the Father, the Son, and the Holy Spirit—without rationalizing

The Athanasian formula

the mystery itself. In the final analysis the point of view thereby remained definitive that the fundamental assumptions of the reality of salvation and redemption are to be retained and not sacrificed to the concern of a rational monotheism.

Characteristically, in all periods of the later history of Christendom in which a rationalistic philosophy was achieved and the history of salvation aspect of the Trinitarian question receded, anti-Trinitarian currents returned. Many, to some extent, consciously rejoined ties with Arius: the humanist Enlightenment of the 16th century and the so-called anti-Trinitarians of the Italian Renaissance. A direct connection exists between anti-Trinitarianism and 18th-century research into the life of Jesus. The oldest life of Jesus researchers in the 18th century, such as Hermann Reimarus and Karl Bahrdt, who portrayed Jesus as the agent of a secret enlightenment order that had set itself the goal of spreading the religion of reason in the world, were at the same time anti-Trinitarians and pioneers of the radical rationalistic criticism of dogma. The Kantian critique of the proofs of God contributed further to a devaluation of Trinitarian doctrine. In the philosophy of German Idealism, Hegel, in the framework of his attempt to raise Christian dogma into the sphere of the conceptual, took the Christian Trinitarian doctrine as the basis for his system of philosophy and, above all, for his interpretation of history as the absolute spirit's becoming self-conscious. In more recent theology, at least in the accusations of some of its critics, the school of dialectical theology in Europe and the United States tended to reduce the doctrine of the Trinity and supplant it with a monochristism.

In a brief but well-publicized episode in the mid-1960s in the United States, a number of celebrated Protestant theologians engaged in cultural criticism observed or announced "the death of God." The theology of the death of God downplayed any notion of divine transcendence and invested its whole claim to be Christian in its accent on Jesus of Nazareth. Christian dogma was reinterpreted and reduced to norms of human sociality and freedom. Before long, however, the majority of theologians confronted this small school with the demands of classic Christian dogma, which insisted on confronting divine transcendence in any assertions about Jesus Christ.

Rediscovery of the transcendence of God

The transcendence of God has been rediscovered by science and sociology; theology in the closing decades of the 20th century endeavoured to overcome the purely anthropological interpretation of religion and once more to discover anew its transcendent ground. Theology has consequently been confronted with the problem of Trinity in a new form, which, in view of the Christian experience of God as an experience of the presence of the Father, Son, and Holy Spirit, cannot be eliminated.

THE DOCTRINE OF MAN

What it is to be human. Most Christian theologians, following the culture and habits of their day, used the general term man to cover both sexes when referring to human beings. The literature on the subject consistently refers to anthropology in theology as "the doctrine of man," but it must be understood as that of "human" or "human being." The starting point for the Christian understanding of what it is to be human is the recognition that humans are created after the image of God. This idea views God and humans joined with one another through a mysterious connection. God is thought of as incomprehensible and beyond substance; yet God desired to reflect the divine image in one set of creatures and chose humans for this. Man as the image of God belongs, therefore, to the self-revelation of God in quite a decisive way. God, being reflected in the human creature, makes this being a partner in the realization of the divine self; there is constant interaction. God and humans belong so closely together that one can say that they are intended for each other. For this the statements of the great mystics are of significance. Man finds fulfillment in God, the divine prototype, but God also first comes to the fulfillment of the divine essence in relation, in this case, with the human.

The human as a creature. The idea of the human being as the creature created according to the image of God was already being interpreted in a twofold direction in the early church. For one thing, man, like all other creatures of the universe, is a creation of God. According to human nature, the creature is thus not divine but at the same time is not created out of nothingness; as creatures human beings stand in a relationship of utter dependency on God. They have nothing from themselves but owe everything, even their being, exclusively to the will of the divine Creator; they are joined with all other fellow creatures through a relationship of solidarity. Later, this idea of the solidarity of the creatures among one another almost completely receded behind the idea of the special position of humans and their special commission of dominion. The idea of solidarity with all creatures has been expressed and practiced by but few charismatic personalities in the history of Western piety, such as by Francis of Assisi in his "Canticle of the Sun": "Praised be Thou, my Lord, with all Thy creatures, especially with our sister sun."

The second aspect of the idea of the human being as a creature operated very much more emphatically: the superiority of humans over all other creatures. God placed humans in a special relationship to the divine. God created them in the divine image, thereby assigning to humans a special commission vis-à-vis all other creatures.

The human as the image of God. Under the influence of the dualistic philosophy of Plato, Christian theology attempted for some time to regard the image of God in human beings as restricted simply to their intellectual capability and faculty of perception. In his work *De Trinitate,* Augustine attempted to ascertain traces of divine Trinity in the human intellect. Christian mysticism confronted this dualistic view of humans. It understood humans in their mind–body entirety as being in the image of God. The image of God is stamped all the way into the sphere of human corporeality. The idea of human creation according to the image of God is already based upon the intention of the Incarnation, the self-representation of God in corporeality. Even according to their somatic (bodily) condition, humans are the universal form of being, in whom the powers and creative principles of the whole universe are combined in a personal unity of spirit, soul, and body.

The Christian understanding of evil is also linked with the idea of human creation according to the image of God. Evil cannot, in the Christian view, be derived from the dualistic assumption of the contrasts of spirit and body, reason and matter. According to the Christian understanding, the triumph of evil is not identical with the victory of matter, the "flesh," over the spirit. Such a dualistic interpretation has frequently been furthered by the fact that for many centuries the Christian understanding of sin, even among many of the church's teachers, was influenced by the philosophical assumptions of Neoplatonic dualism. Moreover, in Augustine there are still the aftereffects of Manichaeism, which—out of the dualistic conceptions of Zoroastrian religion—ultimately viewed the main motive force of sin in "concupiscence"—*i.e.,* the sex drive.

The idea of freedom

The only genuine departure point for the Christian view of evil is the idea of freedom, which is based in the concept of the human being as the image of God. The human is person because God is person. It is apparent in Christian claims that the concept of the human as "being-as-person" is the real seal of that human as "being-as-the-image-of-God," and therein lies the true nobility that distinguishes human beings from all other creatures. If the Christian faith is differentiated from other religions through the fact that for the Christian God is person, then this faith takes effect in the thereby resulting consequence that the human being, too, is person.

God at the same time entered into a great risk in creating the human as person. The real sign of God as personal being is freedom. When God created humans according to his image, he also gave over to them this mark of nobility—*i.e.,* freedom. This alone constitutes the presupposition of love. Only through this freedom can the human being as partner of God offer free love to God; only in this freedom can God's love be answered through free love in return. Love in its fulfilled form, according to the Christian understanding, is possible only between persons;

conversely, the person can be realized only in the complete love to another person. Humans can use this freedom to offer God, their Creator, their freely given love.

Yet, in the gift of freedom itself there also lay enclosed the possibility for humans to decide against God and to raise themselves to the goal of divine love. The event that is portrayed in the Mosaic creation story as the Fall of man (Genesis, chapter 3) is essentially the trying out of freedom, the free decision of humans against God. This rebellion consists of the fact that human beings improperly use their God-given freedom to set themselves against God and even to wish to be "like God."

Human redemption. This special interpretation of sin likewise renders understandable the specifically Christian understanding of human redemption, namely, the view of Jesus Christ as the historical figure of the Redeemer—*i.e.*, the specifically Christian view of the incarnation of God in Jesus Christ.

Members of Asian high religions have found it difficult to understand the fundamental Christian idea of the incarnation. The religious person of the East is inclined to understand the Christian idea of incarnation as an analogy to the Hindu concept of the *avatāra* (best rendered as incarnation). The starting point of the latter is that the divine descends to Earth ever again and is constantly clothed anew in a human figure, in order to reveal the heavenly truth to every era and all people in a manner comprehensible to them. Thus, it was natural to understand the figure of Jesus Christ also as such an *avatāra,* as a form of descent of the divine to mankind. In the realm of Hinduism ever-new attempts are found to comprehend Christology in this sense.

The difference between the Hindu *avatāra* and the Christ

The Christian understanding of the incarnation, however, is based upon a fundamentally different idea, which is enclosed in the simple saying of the Gospel According to John: "The Word became flesh" (chapter 1, verse 14). Whereas the *avatāra* concept assumes that the divine appears in the cyclic lapse of time periods—continually occurring, now in this, now in that earthly veil—the incarnation of the divine Logos in Jesus Christ is, according to the Christian view, a definitively unique happening. One might say that the Christian view of incarnation has an extremely material, even materialistic, feature. In Christianity, it is not a transcendent, divine being that takes on the appearance of an earthly corporeality, so as to be manifested through this semblance of a body; instead, God himself as human, as member of a definite people, a definite family, at a certain time—"suffered under Pontius Pilate"—enters into the corporeality, carnality, and materiality of the history of mankind. In the midst of history God creates the beginning of a thorough transformation of humans that in like manner embraces all spheres of human being—matter, soul, and mind. Incarnation so constituted did not have the character of veiling God in a human form, which would enable the divine being to reveal a new teaching with human words. The incarnation is not the special instance of a cyclic descent of God always occurring afresh in constantly new veils. Instead, it is the unique intervention of God in the history of the human world. Therein God took the figure of a single historical person into the divine being, suffered through the historical conditions of being, and overcame in this person, Jesus Christ, the root of human corruption—the misuse of freedom. God thereby established the dawn of a transformed, renewed, exalted form of human being and opened a realm in which love to God and to neighbour can be tranquilly fulfilled.

The problem of suffering. Here is raised the decisive question of the place of suffering within the Christian anthropology. Christianity's opponents have ever again reproached it with glorifying suffering instead of overcoming it. This reproof seems to many to be not entirely unjustified. There have in fact been eras in the history of Christian piety in which suffering as such underwent a frankly ecstatic glorification. This was especially so in several periods of the Middle Ages, in which the Christian Church was convulsed by the severest inner and outer crises and Christ appeared predominantly in the figure of the man of suffering.

The starting point for the Christian understanding of suffering is the messianic self-understanding of Jesus himself. A temptation to power and self-exaltation lay in the late Jewish promise of the coming of the Messiah–Son of man. The Gospel According to Matthew described the temptation of Jesus by Satan in the wilderness as a temptation to worldly power. Jesus himself deeply disappointed his disciples' notions aiming at power and exaltation, in that he taught them, in accordance with Isaiah, chapter 53: "The Son of man will suffer many things." Already in Jesus' announcements of suffering the Christian understanding of suffering is brought clearly to expression: suffering is not the final aim and end in itself in the realization of human destiny; it is the gateway to resurrection, to rebirth, to new creation. This idea receives its clarification from the Christian understanding of sin. Sin as the misuse of human freedom has led humans into total opposition against God, who in return delivers them over to death. Turning to God can therefore take place only when the results of this rebellion are overcome in all levels of human being, all the way to physical corporeality.

The Christian understanding of suffering

In the early church the sign of the cross was not considered a glorification of suffering but a "sign of victory" (*tropaion*) in the sense of the ancient triumphal sign that was set up at the place where the victorious turning point of the battle took place. The cross was likewise considered the "dread of the demons," since as a victory sign it struck terror into the hitherto ruling demonic powers of the world. An ancient church hymn of the cross spoke of the "cross of the beauty of the Kingdom of God." Christ generally appeared upon early church representations of the cross as the crowned victor, who in such figures is represented as the lord of the new eon, the new age promised in the coming of Christ. The emperor Constantine thus fastened to the standards of the imperial legions the cross, which was considered the victory sign for the community of Christians hitherto persecuted by the Roman Empire, and elevated it to a token of military triumph over the legions of his pagan foes that were assembled under the sign of the old gods.

The crowned victorious Christ

In the Christian understanding, suffering also does not appear—as in Buddhism—as suffering simply under the general conditions of human existence in this world; it is instead coupled with the specifically Christian idea of the imitation of Christ. Individual Christians are called to become imitators of Christ; incorporation into the body of Christ is granted to those who subsequently are ready to carry out within themselves Christ's destiny of suffering, death, and resurrection. The early church's characterization of the Christian was that of *Christophoros*—"bearer of Christ." Suffering was an unalterable principle in the great drama of freedom, which was identical with the drama of redemption.

The resurrection of the body. Just as clear, however, is the real, indeed materialistic, significance that lies in the Christian understanding of the resurrection. A dualistic understanding of what it is to be human, which assumes an essential difference between the spiritual and the material-bodily sides of human existence, necessarily leads to the idea of the immortality of the soul. According to this view, imperishableness belongs to spiritual nature alone. The Christian hope, however, does not aim at the immortality of the soul but at the resurrection of the body. Corporeality is not a quality that is foreign to the spiritual. Everything spiritual presses toward corporealization; its eternal figure is a corporeal figure. This hope was expressed by Vladimir Solovyov:

The resurrection of the body rather than immortality of the soul

> What help would the highest and greatest moral victory be for man, if the enemy, "death," which lurks in the ultimate depth of man's physical, somatic, material sphere, were not overcome?

The goal of redemption is not separation of the spirit from the body; it is rather the new human in the entirety of body, soul, and mind. It is appropriate to say that Christianity has contended for a "holistic" view of the human. The Christian image of the human being has an essentially corporeal aspect that is based in the idea of the incarnation and finds its most palpable expression in the idea of the resurrection.

Progressive human perfection. For a long time Christian anthropology in academic theology was dominated by static thinking. The human appeared as a complete being, placed in a finished world like a methodically provided-for tenant in a prefabricated, newly built residence ready for occupation. Redemption was understood just as statically: salvation appeared in the teachings of church dogma as restitution and restoration of the lost divine image and often in fact more a patching up of fragments through ecclesiastical remedies than as a real new creation.

Although it is not an uncontroversial point, there is in the New Testament, in the observation of many, a progression of salvation in history. Indeed, there is a progress of both the individual human being and of mankind as a whole, what might be thought of under some terms and conditions as a potential for the progressive perfection of the human being. This characteristic stands out already in the proclamation of Jesus. He promises his disciples: "Then the righteous will shine like the sun in the kingdom of their Father. He who has ears, let him hear." (Matthew 13:43). In the Gospel According to John, Jesus promises his disciples an increase of their divine powers that is to exceed even the spiritual powers at work in himself (John 14:12). Similar expectations are also expressed in the First Letter of John: "Beloved . . . it does not yet appear what we shall be, but we know that when he appears we shall be like him, for we shall see him as he is" (chapter 3, verse 2).

The New Testament concept of the progression of salvation

The idea of the Christian "superman," which was expressed by Montanus, is a result of this view. In connection with the breakthrough of the idea of evolution through Darwin in the areas of biology, zoology, and anthropology, the tendency asserted itself—above all in 19th-century American theology—of interpreting the Christian history of salvation in terms of the evolution and expectation of future human perfection in the form of reaching even higher charismatic levels and ever higher means of spiritual knowledge and communication.

In and after the mid-20th century a number of theologians, some of them of schools called "process theology" and some in evolutionary camps, have used these biblical clues to develop new understandings of Christian anthropology. These understandings challenge old orthodoxies, and it cannot be said that any of them have securely been worked into the development of classical thought. Yet these schools, influenced by thinkers such as the British philosopher Alfred North Whitehead or the Jesuit paleoanthropologist Teilhard de Chardin, see the human progressing toward later stages of fulfillment "in Christ."

The thought of Teilhard de Chardin

In such forms of Christian natural theology, Christ is not only a past reference point through the incarnation and a present experience in worship and devotion but also a focal point of the collective salvation of the world. In Teilhard's term, this is the "Omega Point" toward which creation is striving and in respect to which it is unfolding. Such Christian naturalists refer to the New Testament Letter to the Ephesians, where the goal of Christian motion is described: "until we all attain to the unity of the faith and of the knowledge of the Son of God, to mature manhood, to the measure of the stature of the fulness of Christ." (Ephesians 4:13). It must be said that evolutionary theology also met reaction and resistance from many more traditional Christians who operated with other (some would say more scholastic or more static) metaphysics, or who found fault with the thought of Whitehead or Teilhard. At the same time, it is safe to say that through the centuries of change in scientific thought, and with the enlarged cultural experience of Christianity apart from the Western world, ways of thinking about God are certain to be altered.

The justified human. Since the Reformation of the 16th century in the West, the Christian anthropology of Luther, Zwingli, and Calvin has been oriented primarily toward the schema of justification. The Christian is the one to whom the righteousness of God is ascribed in faith for the sake of the merit of Jesus Christ, which he earned for himself through his expiatory sacrifice on the cross. In the 20th century, however, the schema of justification seems less understandable as the starting point for a Christian anthropology, because Jewish law and the Roman Catholic concept of penance based on Roman law (against which the Reformers fulminated) are scarcely found any more in religious consciousness. Paul only speaks of justification when he becomes "as a Jew to the Jews," but if he speaks to Gentile Christians, then he becomes "as a Greek to the Greeks" and talks to them in ideas and images that are more suitable to the Greek ways of thinking in terms of the mystery religions: the new being, the freed and ransomed human, the new creation, the resurrection with Christ, the process of human transformation and supraformation, and the Sonship and friendship of God.

The "new man": The human being in the light of Christ. Probably no idea and no sentiment in the early church dominated the Christian feeling for life so thoroughly and comprehensively as the consciousness of the newness of the life into which persons viewed themselves transposed through participation in the life and body of Christ. The newness of the Christian message of salvation not only filled the hearts of the faithful but was also striking to the non-Christian milieu. The new humans experience and recognize the newness of life as the life of Christ that is beginning to mature in themselves, as the overwhelming experience of a new state already now commencing. In the New Testament statements about the new man, it was not a settled, complete new condition that was being spoken of, into which people are transposed through grace, but rather the beginning of a coming new state, the consummation of which will first take place in the future. The new human is one who is engaged in the process of renewal; new life is a principle of growth of the Christian maturing toward "perfect manhood in Christ." The new situation of human beings, for their part, works anew as fermenting "leaven" within old humankind, as "fresh dough," and contributes to transforming the old form of humanity through its fermentation into the state of the Kingdom of God.

The "reborn human." "Rebirth" has often been identified with a definite, temporally datable form of "conversion." Especially the pietistic and revival type of Christianity has contributed to a certain leveling of this concept. In the history of Christian piety a line of prominent personalities experienced their rebirth in the form of a temporally datable and also locally ascertainable conversion event. Fixation upon a single type of experience, however, is factually not justified. There are numerous other forms of completion of that mysterious event characterized with the expression rebirth. The mode of experience of rebirth itself is as manifold as the individuality of the person concerned, his special intellectual or emotional endowment, and his special history. The different forms of rebirth experience are distinguished not only according to whether the event sets in suddenly with overwhelming surprise, as when one is "born again" or "sees the light," or as the result of a slow process, a "growing," a "maturing," and an "evolution." They are also distinguished according to the psychic capability predominant at the time that thereby takes charge (will, intellect), the endowment at hand, and the personal type of religious experience. With the voluntaristic type, rebirth is expressed in a new alignment of the will, in the liberation of new capabilities and powers that were hitherto undeveloped in the person concerned. With the intellectual type, it leads to an activation of the capabilities for understanding, to the breakthrough of a "vision." With others it leads to the discovery of an unexpected beauty in the order of nature or to the discovery of the mysterious meaning of history. With still others it leads to a new vision of the moral life and its orders, to a selfless realization of love of neighbour. In the experience of Christian rebirth, the hitherto existing old condition of humanity is not simply eliminated so far as the given personality structure is concerned—a structure dependent upon heredity, education, and earlier life experiences. Instead, each person affected perceives his life in Christ at any given time as "newness of life."

Forms of "rebirth"

Human liberation. The condition of "fallen" humanity is frequently characterized in the New Testament as "slavery." It is the slavery of human willfulness that wants to have and enjoy all things for itself: the slavery of alienated love, which is no longer turned toward God but toward

The problem of slavery: internal and external

one's own self and the things of this world and which also degrades one's fellows into the means for egoism and exploitation. The servitude of people fallen away from God is much more oppressive than mere slavery of the senses and of greed for life. It is the enslavement not only of their "flesh" but also of all levels of their being, even the "most spiritual."

In a bold reversal of the language of Platonic dualism, Luther expressed it thusly in his commentary to the Letter of Paul to the Romans: "The entire man who is not reborn is flesh, even in his spirit; the entire man who is reborn is spirit, even when he eats and sleeps." Only from this perspective do Martin Luther's words about the "Freedom of a Christian Man" (1520) receive their true meaning. The freedom that Christians receive is the freedom that Christ, spoken of by Paul as the new Adam, gained for them by fighting. The freedom of Christians is the freedom reattained in Christ, in which the possibility of the misuse of freedom is addressed and overcome.

In the initial centuries of the church a special significance fell to the evangelical schema of liberation—and to the corresponding schema of ransom—in a society that, in its social structure, was constructed entirely upon the system of slavery. On the one hand, wide strata of the population lived in the permanent state of slavery; on the other hand, on the basis of the prevailing usage of war, even the free population was constantly exposed to the danger of passing into possession of the victor as a slave in case of a conquest. The schema of liberation could therefore count upon a spontaneous understanding.

Freedom alone also makes a perfect community possible. Such a community embraces God and the neighbour, in whom the image of God confronts human beings in the flesh. Community is fulfilled in the free service of love. Luther probably most pertinently articulated the paradox of Christian freedom, which includes both love and service: "A Christian man is a free lord of all things and subordinate to no one. A Christian man is a submissive servant of all things and subject to everyone." Christian freedom is thus to be understood neither purely individually nor purely collectively. The motives of the personal and the social are indivisibly joined by the idea that each person is indeed an image of God for himself alone, but that in Christ he also recognizes the image of God in the neighbour and with the neighbour is a member in the one body of Christ. Here, too, the evolutive principle of the idea of freedom is not to be mistaken; in it, for example, lay the spiritual impetus to the social and racial emancipation of slaves, as it was demanded by the great Christian champions of human rights in the 18th and 19th centuries and, through great efforts, pursued and achieved.

Joy in human existence. Friedrich Nietzsche summarized his critique of the Christians of his time in the words of Zarathushtra (Zoroaster): "They would have to sing better songs to me that I might believe in their Redeemer: his disciples would have to look more redeemed!" The critique is to the point. In the New Testament testimonials, joy appears as the characteristic mark of distinction of the Christian. It is the spontaneous result of being filled with the Holy Spirit and is among the main fruits of the Holy Spirit. Joy was the basic mood of congregational gatherings and was often expressed in an exuberant jubilation; it has its origin in the recognition that the dominion of evil is already broken through the power of Christ, that death, devil, and demons no longer possess any claim upon believers, and that the forces of forgiveness, reconciliation, resurrection, and transfiguration are already effective in humankind. This principle of the joy of the Christian is most strongly alive in the liturgy of the Eastern Orthodox Church.

Joy as a characteristic mark of a Christian

The roots of a specifically Christian sense of humour also lie within this joy. Its peculiarity consists of the fact that in the midst of the conflicts of life the Christian is capable of regarding all sufferings and afflictions from the perspective of overcoming them in the future or from the perspective of victory over them already achieved in Christ. In Christian humour, freedom and joy are combined. The Christian does not let himself be confused and tempted through cross and suffering but already perceives in the cross and in suffering a foretaste of eschatological triumph and joy. At one extreme the humour of the Danish philosopher Søren Kierkegaard is too dialectical and too bitter to exhaust the entire fullness of the Christian joy. More of it is found in the "hallelujah" of black spirituals.

The charismatic believer. In the New Testament the Christian is depicted as the person who is filled with the powers of the Holy Spirit. The view of the gifts of the Spirit stands in a direct relationship with the understanding of the human as the image of God. For the believing Christian of the original period of the church, the Holy Spirit was the Spirit of the Lord Jesus Christ, who is already now made manifest in his body, the community of the faithful, as the miraculous principle of life of the new eon. Throughout the centuries the Holy Spirit has remained the ferment of church history—all great reformations and numerous foundings of new churches and sects stand under the banner of new charismatic breakthroughs.

The Holy Spirit as the ferment of the church

Christian perfection. The demand for perfection is frequently repeated in the New Testament and has played a significant role in the history of Christian spirituality. In the Gospel According to Matthew, Jesus directs the demand to his disciples: "You, therefore, must be perfect, as your heavenly Father is perfect" (chapter 5, verse 48). This demand seems to exceed by far the measure of reasonableness for man. Yet, it is meant literally, for it is asserted again in the writings of the New Testament. The meaning of this claim is recognizable only from the understanding of the human as the image of God and from the apprehension of Christ as the "new Adam." The perfection of believers is the perfection with which they reflect the image of God. They have, to be sure, disfigured this image through willful alienation from the original, but in Christ they recover the perfection of the image of God.

The idea of the deification of man, which captures the Greek notion of "partaking" of the divine character, also points in the direction of perfection. Post-Reformation theology, out of anxiety before "mysticism," struck almost entirely from its vocabulary this concept that originated in the techniques of the mystical experience. In the first one and a half millennia of the Christian Church, however, the idea of deification—of partaking in God's being—constituted a central concept for Christian anthropology. Athanasius created the fundamental formula for the theology of deification: "God became man in order that we become God." In the theology of the early church these words became the basis of theological anthropology. Only the idea of perfection makes understandable a final enhancement of the Christian image of the human—the intensification from "child of God" to "friend of God." This appears as the highest form of communion reached between God and human beings; in it love is elevated to the highest form of personal communication between prototype and image.

Fellow humans as the present Christ. That revolutionizing idea, which constitutes the basis of Christian ethics, also becomes comprehensible through the foundation of Christian anthropology in the image of God: in the eye of Christian faith Christ is present in everyone, even the most debased. According to Matthew (chapter 25, verses 40 and 45) the Judge of the world says to the redeemed: "Truly, I say to you, as you did it to one of the least of these my brethren, you did it to me," and to the damned: "As you did it not to one of the least of these, you did it not to me." Another saying of the Lord is cited by Tertullian: "If you have seen your brother, you have seen your Lord." For the Christian the fellow human is the present Christ himself. In the fellow, Christians see, under the wrapping of misery, degeneration, and suffering, the image of the present Lord, who became human, who suffered, died, and was resurrected in order to lead all humanity back into the Kingdom of God.

Christ as present in everyone

In the self-understanding of the Christian community two tendencies battle with one another from the beginning of church history. They lead to completely different consequences in the basic orientation of Christians toward fellow Christians and fellow human beings.

The one attitude stands under the governing idea of election. God chooses some out of the human race, which

exists in opposition to all that is divine, and erects a Kingdom from these elect. This idea underlines the aristocratic character of the Kingdom of God; it consists of an elite of elect. In the Johannine apocalypse the 144,000 "... who have not defiled themselves with women" (Revelation 14:4) constituted the picked troops of the Kingdom of God. For Augustine and his theological successors up to Calvin, the community of the elect is numerically restricted; their number corresponds to the number of fallen angels, who must again be replaced through the matching number of redeemed men so that the Kingdom of God would again be restored numerically as well. The church is here understood as a selection of a few out of the masses of perdition who constitute the jetsam of the history of salvation. A grave endangering of the consciousness of community is concealed in this orientation, for self-righteousness, which is the root of self-love and thereby the death of love of neighbour, easily enters again via this consciousness of exclusive election.

The other attitude proceeds from the opposite idea that the goal of the salvation inaugurated through Jesus Christ can only be redemption of all humanity. According to this view God's love of humans (*philanthrōpia*), as the drama of divine self-surrender for human salvation shows, is greater than the righteousness that craves the eternal damnation of the guilty. Since the time of Origen, this second attitude is found not only among the great mystics of the Eastern Church but also among some mystics of Western Christendom. The teaching of universal reconciliation (*apokatastasis pantōn*) has struck against opposition in all Christian confessions. This is connected with the fact that such a universalistic view easily leads to a disposition that regards redemption as a kind of natural process that no one can evade. Such an orientation can lead to a weakening or loss of a consciousness of moral responsibility before God and neighbour; it contains the temptation to spiritual security and moral indolence.

THE CHURCH

The relationship of the Christian and Jewish concepts of the people of God

The Christian view of the church was influenced by the Old Testament concept of the *qahal,* the elected people of God of the end time, and by the expectation of the coming of the Messiah in Judaism. The Greek secular word *ekklēsia,* the term used for the church, means an assembly of people coming together for a meeting.

In Christianity the concept received a new meaning through its relationship to the person of Jesus Christ as the messianic inaugurator of the Kingdom of God: (1) with Christ the elected community of the end time has appeared; (2) the church is the eschatological gift of the Holy Spirit, which already flows through the life of the church (Acts 2:33); (3) the community of the end time consists of those who believe in Jesus Christ—both Jews and pagans; the idea of the elected convenant people (*i.e.,* the Jews) is transferred to the "new Israel"; (4) the church forms the body of its Lord; and (5) the church consists of "living stones," from which its house is "built" (1 Peter 2:5).

Jesus himself created no firm organization for his community; the expectation of the immediate imminence of the Kingdom of God provided no occasion for this. Nevertheless, the selection of Apostles and the special position of individual Apostles within this circle pointed to the beginnings of a structuralization of his community. After the community was constituted anew because of the impressions made by the appearances of the Resurrected One, the succession of the appearances apparently effected a certain gradation within the community.

The unity of the church, which was dispersed geographically, was understood from the viewpoint of the Diaspora (James 1:1—the scattered churches of the new Israel represent "the twelve tribes in the Dispersion"). The *Didachē,* or the *Teaching of the Twelve Apostles* (late 1st century), viewed the church in terms of the bread of the Eucharist, whose wheat grains "are gathered from the mountains." The idea of the preexistence of the divine Logos brought into existence the concept of the preexistence of the church, which included the view that the world was created for the sake of the church. The earthly church is thus the representative of the heavenly church.

Normative defenses in the early church. Establishment of norms for the church was necessary because diverse kinds of interpretations of the Christian message were conceived under the influence of the religions of late antiquity, especially Gnosticism—a syncretistic religious dualistic belief system that incorporated many Christian motifs and became one of the strongest heresies of the early church. In Gnostic interpretations, mixed Christian and pagan ideas appealed to divine inspiration or claimed to be revelations of the Resurrected One. The church erected three defenses against the apparently uncontrollable prophetic and visionary efficacy of pneumatic (spiritual) figures as well as against pagan syncretism, which was represented by a mixing together of many divine images and expressions: (1) the New Testament canon, (2) the apostolic "rules of faith," or "creeds," and (3) the apostolic succession of bishops. The common basis of these three defenses is the idea of "apostolicity."

Reasons for the development of the canon, creed, and episcopacy

The early church never forgot that it was the church that created, selected the books, and fixed the canon of the New Testament, especially because of the threat of Gnostic writings. This is one of the primary distinctions between the Orthodox Church vis-à-vis the Reformation churches, which view the Scriptures as the final norm and rule for the church and church teaching. The Orthodox Church, like the Roman Catholic Church, emphasizes the fact that the Christian Church existed prior to the formation of the canon of Scripture—that it is indeed the source and origin of the Scripture itself. Thus, tradition plays a significant role alongside the Holy Scriptures in the Orthodox and Roman churches.

The apostolic rule of faith—*i.e.,* the creed—issued from the apostolic tradition of the church as a second, shorter form of its solidification, at first oral and then written. It also served as a defense against Gnosticism and syncretistic heretical interpretations of the Christian faith.

The third defense that the church used against both Gnostic and syncretistic movements and free charismatic movements within the church was the office of bishop, which became legitimized through the concept of apostolic succession. The mandate for missions, the defense against free prophecy, the polemics with Gnosticism and other heresies, the persecution of the church, and, not least of all, management of church discipline—all allowed the monarchical episcopacy to emerge as a strong jurisdictional office in the early centuries. The bishop, in his capacity as leader of the eucharistic worship service, as teacher, and as curer of souls, became the chief shepherd of the church and was considered its representative.

The basic idea of apostolic succession is as follows: Christ appointed the original Apostles and entrusted to them his full spiritual authority; the original Apostles then appointed overseers (bishops) for the churches founded by them and passed on to them, through the sacramental laying on of hands, their authority of office. These men transmitted the office of overseer to their successors also by the laying on of hands. In this manner, apostolic succession guaranteed the legitimacy of episcopal church government, episcopal doctrine, and the validity of the sacraments dispensed by the bishops.

Evolution of the episcopal office. The evolution of the episcopal office followed a different development in the East and in the West. The Orthodox Church accepts the monarchical episcopacy insofar as it involves the entire church, both the visible earthly and the invisible heavenly churches bound together inseparably. The monarchical principle, however, finds no application to the organization of the visible church. The latter is based upon democratic principles that are grounded in the polity of the early church. Just as all Apostles without exception were of equal authority and none of them held a paramount position over against the others, so too their successors, the bishops, are of equal authority without exception.

Democratic principles in the Orthodox Church

Thus, the politics of the Eastern Orthodox churches have a decidedly synodal character. Not only the priesthood but also the laity have been able to participate in Orthodox synods. Election to ecclesiastical offices (*i.e.,* pastor, bishop, or patriarch) involves participation by both clergy and laity. The individual polities of modern Orthodox

churches (*e.g.*, Greek or Russian) are distinguished according to the amount of state participation in the settlement of ecclesiastical questions.

The ecumenical council, which consists of the assembly of all Orthodox bishops, constitutes the highest authority of Orthodox synodal polity. The bishops gathered at an ecumenical council resolve all questions of Orthodox faith as well as of worship and canon law according to the principle that the majority rules. The councils recognized by the Orthodox Church as ecumenical councils are: Nicaea in 325, Constantinople in 381, Ephesus in 431, Chalcedon in 451, second Council of Constantinople in 553, third Council of Constantinople in 680, and second Council of Nicaea in 787. No council since then has been regarded as ecumenical by Eastern Orthodoxy.

Orthodoxy was divided into various old and new types of churches. Some of these were "patriarchal," which meant that they were directly responsible to a patriarch. Others were "autocephalous," which has come to mean in the modern world that as national churches they are in communion with Constantinople but are responsible for authority to their own national synods. This division, plus the fact that Orthodoxy has so often been the victim of revolutionary change and political onslaught, has served as a hindrance against any new ecumenical council, even though many Orthodox have asked for such a council.

The causes of the monarchical episcopate in the West

On the basis of the joint action of special circumstances, in the Roman Church the papacy evolved out of the monarchical episcopate. Rome, as the capital of the Roman Empire, in which a numerically significant Christian community was already formed in the 1st century, occupied a special position. A leading role devolved upon the leading bishop of the Roman community in questions of discipline, doctrine, and ecclesiastical and worship order. This occurred in the Latin provinces of the church in the West (Italy, Gaul, Spain, Africa), whose organization followed the provincial organization of the Roman Empire. A special leadership position devolved upon the Roman bishop after the collapse of the Western Roman Empire. The theological underpinning of this special position was emphasized by Petrine theology, which saw in the words of Jesus, "You are Peter, and on this rock I will build my church" (Matthew 16:18), a spiritual-legal instituting of the papacy by Jesus Christ himself. In the Greek Church of the East (*e.g.*, Origen) and also in Augustine in the West, however, these words were referred to Peter's confession of faith; since the time of the popes Gelasius I (reigned 492–496), Symmachus (reigned 498–514), and Gregory I (reigned 590–604), these words have served as the foundation for the claim of papal primacy over the entire Christian Church.

The tendency of Christianity toward intolerance

Authority and dissent. Christianity, from its beginning, tended toward an intolerance that was rooted in its religious self-consciousness. Christianity understands itself as revelation of the divine truth that became human in Jesus Christ himself. "I am the way, and the truth, and the life; no one comes to the Father, but by me" (John 14:6). To be a Christian is to "follow the truth" (3 John); the Christian proclamation is "the way of truth" (2 Peter 2:2). Those who do not acknowledge the truth are enemies "of the cross of Christ" (Philippians 3:18) who have "exchanged the truth about God for a lie" (Romans 1:25) and made themselves the advocates and confederates of the "adversary, the devil," who "prowls around like a roaring lion" (1 Peter 5:8). Thus, one cannot make a deal with the devil and his party—and in this lies the basis for intolerance in Christianity.

Christianity consistently practiced an intolerant attitude in its approach to Judaism and paganism as well as heresy in its own ranks. By practicing its intolerance vis-à-vis the Roman emperor cult, it thereby forced the Roman state, for its part, into intolerance. Rome, however, was not adapted to the treatment of a religion that negated its religious foundations, and this inadequacy later influenced the breakdown of paganism.

Early Christianity aimed at the elimination of paganism—the destruction of its institutions, temples, tradition, and the order of life based upon it. After Christianity's victory over Greco-Roman religions, it left only the ruins of paganism still remaining. Christian missions of later centuries constantly aimed at the destruction of indigenous religions, including their cultic places and traditions (as in missions to the Anglo-Saxons, Germans, and Slavs). This objective was not realized in mission areas in which Christian political powers did not succeed in conquests—*e.g.*, China and Japan; but in Indian Goa, for example, the temples and customs of all indigenous religions were eliminated by the Portuguese conquerors.

The furtherance of intolerance in confrontations with Islām

The attitude of intolerance was further reinforced when Islām confronted Christianity from the 7th century on. Islām understood itself as the conclusion and fulfillment of the Old and New Testament revelation; from the Christian view, however, Islām was understood eschatologically—*i.e.*, as the religion of the "false prophets," or as the religion of the Antichrist. The aggression of Christianity against Islām—on the Iberian Peninsula, in Palestine, and in the entire eastern Mediterranean area during the Crusades—was carried out under this fundamental attitude of intolerance. Intolerance of indigenous religions was also manifested in Roman Catholic missions in the New World; these missions transferred the methods of the struggle against Islām to the treatment of the Native Americans throughout the Western Hemisphere and destroyed their cults and cultic places. Against Protestants, the Counter-Reformation displayed the same kind of intolerance and was largely equated with the struggle against the Turks.

The idea of tolerance first arose during a series of historical catastrophes that forced Christianity into self-reflection: the devastating impressions of the military proceedings of the Inquisition troops against the heretical Cathari, Albigenses, and Waldenses during the Middle Ages; the psychological effect of the permanent inquisitional terror; the conquest of Constantinople by the Turks; the fratricidal struggle among the churches that arose during the Reformation; and the battles of the Protestant territorial churches against the sectarian and Free Church groups in their midst.

Thus, for Nicholas of Cusa (1401–64) the conquest of Constantinople became the occasion to demand, for the first time, the mutual toleration of Christianity and Islām as the presupposition for a religious peace. When the Reformation churches asserted the exclusive claim of possessing the Christian truth, they tried to carry it out with the help of the political and military power at their disposal. In the religious wars of the 16th and 17th centuries, Christian intolerance developed into an internal fratricidal struggle in which each side sought to annihilate the other party in the name of truth. Only the fact that such attempts did not succeed led to new reflections upon the justification of one's own exclusive claim to absoluteness.

The intolerance of the Reformation territorial churches found its counterpart in the intolerance of the revolutionary groups of the Reformation period, such as that of the German radical Reformer Thomas Müntzer, which wanted to force the coming of the Kingdom of God through the dominion of the "elect" over the "godless." In the intolerance of the ideology and techniques of many modern political revolutions and authoritarian regimes some see either a legacy or a mimicking of old Christian patterns and methods (*e.g.*, inquisition or brainwashing).

Among those who first spoke up consistently for tolerance were the Baptists and Spiritualists of the Reformation period. Their most important contribution consisted in that they stood up for their constantly reiterated demand for tolerance not only through their preaching but also through their courageous suffering.

The victory of tolerance over intolerance

The victory of tolerance contributed especially to the recognition of the evident contradiction between the theological self-conception of Christianity as a religion of love of God and neighbour and the inhumanity practiced by the churches in the persecution of dissenters. Recognition of this contradiction even provoked criticism of the Christian truths of faith themselves.

The Roman Catholic Church in the past has consistently opposed the development of religious toleration. Its claim to absolute power in a state is still practiced in the 20th century in some Catholic countries, such as Spain and Colombia, in relationships to Protestant minorities. Since

Pope John XXIII and the second Vatican Council (1962–65), however, a more tolerant attitude of the Roman Catholic Church has been demanded that is appropriate both to the ecumenical situation of Christendom in the latter part of the 20th century and to the personal character of the Christian faith.

Creeds and confessions. The faith of Christendom is present in the confessions of faith and the creedal writings of the different churches. Three creeds find general ecumenical acknowledgment: the Apostles' Creed, the Nicene–Constantinopolitan Creed (also called the Nicene Creed), and the Athanasian Creed. The Apostles' Creed is the baptismal confession of the Roman Catholic community; its original form as a Greek hymn can be traced back to the apostolic tradition (of the 2nd century). The Nicene–Constantinopolitan Creed is the confession of faith of the ecumenical Council of Nicaea in 325, which was later supplemented at the ecumenical Council of Constantinople in 381. Its principal use is in the liturgy of the Eucharist. The Athanasian Creed is a Latin creed whose theological content can be traced back to Athanasius of Alexandria (4th century) but that probably first originated in the 5th century in Spain or southern Gaul. It contains a detailed formulation of the doctrine of the Trinity and Christology (the two-natures doctrine), which was influenced by Augustine. All three creeds were accepted by the churches of the Reformation.

Acceptance of the three ecumenical creeds

Around central confessional statements about Jesus as the Christ in the New Testament—*e.g.*, "Jesus is Lord" (Romans 10:9); "You are the Christ" (Matthew 16:16)—are concentrated a series of further assertions that laud his significance for salvation and concern his suffering, death by crucifixion, Resurrection, and his exaltation to God. This tradition, through Mark, Luke, and Paul, was called "gospel," or kerygma (proclamation).

The original form of the creed possessed not a didactic but a hymnal character and had its locus in the worship service. Regular use of a creed as a baptismal confession, and, accordingly, in the preparation of candidates for baptism in catechetical instruction, influenced its fixed formulation. This was also true of its use in the eucharistic worship service as an expression of the congregation's unity in faith before receiving the elements of the Lord's Supper as well as its use as testimony before the world in times of persecution and as norm of faith (*regula fidei*) in the altercation with heresies.

Development of confessions

Development of confessions of faith into theological didactic creeds, which began during the Christological controversies of the 5th century, was continued in the Reformation. The relatively short creedal formulas grew into extensive creedal compositions, primarily because the Reformers conducted their battles with the Roman Church as a struggle for "pure doctrine" as well as for a foundation for the unity of the church. In the Diet of Augsburg in 1530 the feuding ecclesiastical parties were induced to deliver a presentation of their faith. Though the Roman Catholics did not accede to this challenge, the Protestants offered the Confessio Augustana (or the Augsburg Confession). First planned by Philipp Melanchthon, a follower of Luther, as a creed for union, it later became the basic confessional statement of the Lutheran Church.

The formation of various Protestant confessions was achieved in the individual territorial churches and led to the development of diverse *corpora doctrinae* ("bodies of doctrines"). The differences of the traditional creeds and adherence to them are still clearly noticeable in the ecumenical movement of the 20th century.

A similar development of doctrinal confessions occurred in Calvinism. The idea of the completion of confessional writings is missing in the Lutheran churches but not in Calvinistic churches: the revision of old and the formation of new creedal writings are permitted and in part are provided for in the rules of the church. Thus the Barmen Declaration in 1934, against the "German Christians" and the Nazi worldview, arose primarily from Reformed circles. The Anglican Church incorporated the Thirty-nine Articles (a confessional statement) and a short catechism into *The Book of Common Prayer* of 1559/1662 (revised in the United States by the Protestant Episcopal Church in 1928 and 1979) and thereby emphasized the unity of doctrine and worship.

Of the denominations that arose out of the Reformation churches, most created doctrinal documents that are comparable to the reformational confessional writings (*e.g.*, among Methodists, Baptists, and Congregationalists). Some denominations (*e.g.*, the Quakers, the Disciples of Christ, and some Baptists), on the other hand, have rejected any form of creed because they believe creeds to be obstacles to the Christian faith, thus conflicting with the freedom of the Holy Spirit.

The shifting of the chief emphasis in church life to "pure doctrine" in the 16th and 17th centuries also obliged the Orthodox and Roman Catholic churches to formulate their teaching in confessional texts. Thus, under the influence of the reformational creedal writings, the Eastern Orthodox Church developed confessional texts. An example is *The Orthodox Confession of Faith* (*Confessio orthodoxa*) of the metropolitan Peter Mogila of Kiev against Cyril Lucaris, a Calvinist-influenced patriarch of Constantinople; it was approved in 1643 by the Greek and Russian patriarchs. At the Council of Trent (1545–63) the Roman Catholic Church countered the Protestant doctrinal creeds with a *Professio fidei Tridentina* ("The Tridentine Profession of Faith"), which at the end of every article of faith respectively anathematizes the dissenting Protestant article of faith.

Creedal formulations in the 20th century

In modern Christendom, creedal formulation is continued in two areas. (1) Within the ecumenical movement, since the formation of the World Council of Churches in 1948 there have been attempts to create a brief uniform confession as the common basis of faith for the Christians in that council. These efforts have not yet been concluded. According to its constitution, the World Council of Churches is "a fellowship of Churches which accepts our Lord Jesus Christ as God and Saviour." In 1960 at St. Andrews, Scot., the World Council's central committee unanimously accepted an expanded draft of the "basis":

> The World Council of Churches is a community of churches which confess the Lord Jesus Christ, according to the Holy Scriptures, as God and Savior and therefore seek to fulfill that to which they are jointly called, to the glory of God the Father, the Son and the Holy Spirit.

This new version ensued mainly at the instigation of the Orthodox churches, for whom the hitherto existing form of the "basis" was not adequate.

The movement of Roman Catholicism into the interconfessional orbit after the second Vatican Council complicated attempts to draft a modern ecumenical confession. The Roman Catholic Church is not a member of the World Council, but conciliar Protestant and Orthodox members are reluctant to make major moves without considering Roman Catholic interests.

(2) There are great numbers of churches—the majority, many would contend—that are products of missionary endeavours by the West. For a time they were called "the younger churches" but are now more frequently referred to simply as Asian or African churches, or churches in developing nations. Among them the doctrinal disputes and confessional battles of Western Christendom have often been viewed as alien, imported, and frequently incomprehensible. The union of churches in South India into the Church of South India (1947) occurred only on the basis of the participating churches dismantling their traditional creedal differences. The Church of South India's scheme of union substitutes biblical revelation for doctrinal formulation. Similarly, the United Church of Christ in Japan (Kyodan) renounced drawing up a new creed and limited itself to a preface to the Apostles' Creed. In the churches of Africa, the inadequacy of the confessions of the 16th century also has been strongly recognized as a result of their own indigenous cultural presuppositions.

Areas in which early Christians sometimes violated ideals of holiness

Organization. In the early church, discipline—qualified by the ideal of holiness demanded from baptized Christians—concerned four areas in which there arose violations of the demand for holiness: (1) the relationship to the pagan social milieu and the forms of life and culture connected with it (*e.g.*, idolatry, the emperor's cult, the theatre, and the circus); (2) the relationship of the

sexes within the Christian community (*e.g.*, rejection of polygamy, prostitution, pederasty, sodomy, and obscene literature and art); (3) other offenses against the community, especially murder and property crimes of all kinds; and (4) the relationship to teachers of false doctrine, false prophets, and heretics.

Employment of church discipline at an early date led to the formation of a casuistry that at first consisted simply of the distinction between "mortal" and "not mortal" sins (1 John 5:15 ff.)—*i.e.*, between sins that through their gravity resulted in loss of eternal life and those with which this was not the case. In earliest Christianity, the relapse of a baptized Christian into paganism (*i.e.*, apostasy) was believed to be the most serious offense. In the Letter to the Hebrews one who is baptized irrevocably forfeits salvation through a relapse into grievous sin. The various difficulties in substantiating the theory and practice of a second repentance were solved by Pope Calixtus (reigned 217/218–222). This question was especially important in Rome because of the great number of offenses against the idea of holiness. Pope Calixtus granted to bishops decisions about definitive exclusion from the congregation or readmission as well as the evaluation of church punishments. Among all the factors that led to the power of the episcopacy, the concentration of penitential discipline in the hands of the bishop probably contributed more to the strengthening of episcopal power and to the achievement of the monarchical episcopate in the church than any other single factor. This development did not take place without fierce opposition (*e.g.*, Montanism).

Attainment of the church's demand of holiness was made more difficult in the large cities, especially in reference to sexual purity. The period of persecution by the pagan emperors and the legal constraint to performance of sacrifice before the altars of the emperor's images brought countless new instances of apostasy. The so-called Lapsi (Lapsedones), who had performed sacrifices before the emperor's image but, after persecution, faded away and then moved back into the churches again, became a serious problem for the church, sometimes causing schisms (*e.g.*, the Donatists).

The execution of church discipline by the clergy was subordinated to the regulations of canon law provided for priests. A genuine practice of church discipline was maintained in the monasteries in connection with the public confession of guilt, which was made by every monk before the entire assembly in the weekly gatherings of the chapter. A strong revival of church discipline among the laity also resulted from the church discipline pursued within monasticism.

Results of the externalization of church discipline

On the whole, the casuistic regulation of church discipline led to its externalization and devaluation. The medieval sects, therefore, always stressed in their critique of the worldly church the lack of spiritual discipline and endeavoured to realize a voluntary church discipline in terms of a renewed radical demand of holiness based on early Christianity. The radical sects that emerged in the Reformation reproached the territorial churches by claiming that they had restricted themselves to a renovation of doctrine and not to a renewal of the Christian life and a restoration of the "communion of saints." Different groups of Anabaptists (*e.g.*, Swiss Brethren, Mennonites, and Hutterites), especially, attempted to realize the ideal of the purity and holiness of the church through the reintroduction of a strict church discipline.

The Reformed churches in particular endeavoured to make church discipline a valid concern of the community. In Geneva, church discipline was expressed, at the instigation of Calvin, in the establishment of special overseers, who, in the individual districts assigned to them, had to watch over the moral behaviour of church members. There likewise came about the creation of such social arrangements as ecclesiastically controlled inns and taverns, in which not only the consumption of food and drink but even the topics of conversation were subject to stern regulation. The cooperation of ecclesiastical discipline and state legislation found its characteristic expression in the United States in the Prohibition amendment to the Constitution. Its introduction came most strongly from congregational churches, above all those characterized by Evangelical, Fundamentalist, or Pentecostal outlooks. They united forces with more moderate or liberal churches that were experienced in trying to affect the social order through legislation. Together they battled against the misuse of alcohol as part of their ideal to extend Christian norms and influence to the whole of society.

In the 20th century, church discipline, in the original spiritual sense of voluntary self-control, is practiced only in smaller communities of evangelical Christians, in which the ideal of holiness of the community is still maintained and in which the mutual, personal bond of the congregational members in the spirit of Christian fellowship still allows a meaningful realization of a church discipline. It is also practiced in churches in developing nations. In these churches the practice of church discipline still appears as a vitally necessary centre of the credible self-representation of the Christian community. Characteristically, therefore, these churches' main criticism of the old institutional churches has been directed against the cessation of church discipline among their members.

The development of the episcopacy in the Orthodox and Roman Catholic churches has been covered in the general introduction of this section under evolution of the episcopal office. Occupying a special position is the episcopal polity of the Anglican Communion. Despite the embittered opposition of Puritan and independent groups during the period of the Reformation and Revolution in England, this polity has maintained the theory and practice of the episcopal office of apostolic succession. The Low Church tradition of the Anglican Communion views the episcopal office as a form of ecclesiastical polity that has been tested through the centuries and is therefore commendable for pragmatic reasons; the Broad Church tradition, however, emphatically adheres to the traditional worth of the episcopal office without allowing the faithful to be excessively dependent upon its acknowledgement. The High Church tradition, on the other hand, values episcopal polity as an essential element of the Christian Church that belongs to the church's statements of faith. The episcopal branch of the Methodist Church has also retained in its polity the bishop's office in the sense of the Low Church and Broad Church view.

Episcopacy in Anglican and other Reformation churches

In the Reformation churches an episcopal tradition has been maintained in the Swedish state church (Lutheran), whose Reformation was introduced through a resolution of the imperial Diet of Västerås in 1527, with the cooperation of the Swedish bishops. In the German Evangelical (Lutheran and Reformed) territories, the bishops' line of apostolic succession was ruptured by the Reformation. As imperial princes, the Roman Catholic German bishops of the 16th century were rulers of their territories; they did not join the Reformation in order to avoid renouncing the exercise of their sovereign (temporal) rights as demanded by Luther's Reformation. On the basis of a legal construction originally intended as a right of emergency, the Evangelical rulers functioned as the bishops of their territorial churches but only in questions concerning external church order. This development was promoted through the older conception of the divine right of kings and princes, which was especially operative in Germanic lands.

In matters of church polity, controversial tendencies that began in the Reformation still work as divisive forces within the ecumenical movement in the 20th century. For Luther and Lutheranism, the polity of the church has no divine-legal characteristics; it is of subordinate significance for the essence of the church, falls under human ordinances, and is therefore quite alterable. In Calvinism, on the other hand (*e.g.*, in the *Ecclesiastical Ordinances* [*Ordonnances ecclésiastiques*] of 1541 and in Calvin's *Institutes of the Christian Religion* [1536]), the Holy Scriptures appear as a codex from which the polity of the congregation can be inferred or certainly derived as a divine law. Thus, on the basis of its spiritual–legal character, church polity would be a component of the essence of the church itself. Both tendencies stand in a constant inner tension with one another in the main branches of the Reformation and within the individual confessions as well.

Even in Lutheranism, however, there has been a demand

for a stronger emphasis upon the independent episcopal character of the superintendent's or president's office. Paradoxically, in the Lutheran Church, which came forth with the demand of the universal priesthood of believers, there arose the development of ecclesiastical authorities but not the development of self-contained congregational polities. When a merger of three Lutheran bodies produced a new Evangelical Lutheran Church in America in 1988 it established the bishop as leader of the synodal jurisdictions. In Lutheranism these bishops replaced presidents. Bishops were regarded there, as in Methodism, as part of the *bene esse,* the well-being, and not the *esse,* the essence, of the church. More or less self-contained congregational polities were developed in many Reformed churches because the Reformed Church congregation granted greater participation in the life of the congregation to the laity as presbyters and elders. Furthermore, the Reformed Church areas in Germany, France, England, and Scotland, as well as in The Netherlands and Hungary, had to build up their own ecclesiastical structure without dependence upon state authorities.

Among the conservative but often spontaneous evangelical Protestant churches diverse forms of polity have developed. They have all been founded with an appeal to the Holy Scriptures. Their prototypes can, in fact, be identified in the multiformity of congregational polities in the first three centuries before the victory of the monarchical episcopal office.

The model of the original church

Presbyterian polity appeals to the model of the original church. The polity of the Scottish Presbyterian Church and the Presbyterian churches of North America is primarily based upon this appeal, which was also found among many English Puritan groups. It proceeds from the basic view that the absolute power of Christ in his church postulates the equality of rights of all members and can find expression only in a single office, that of the presbyter. The calling to this office is through election by church members, formally analogous to the democratic, republican political mode, and, accordingly, in contrast with the monarchy of the papal and the aristocracy of the episcopal church polity. In Presbyterian churches the differences between clergy and laity have been abolished in theory and, to a great extent, in practice. A superstructure of consistories and presbyteries is superposed one upon the other, with increasing disciplinary power and graduated possibilities of appeal. Through their emphases upon the divine–legal character of Presbyterian polity, the Presbyterian churches have represented a Protestant polity that counters the Roman Catholic concept of the church in the area of ecclesiastical polity. In ecumenical discussions in the 20th century, the divine–legal character of this polity is occasionally noticeable in its thesis of an apostolic succession of presbyters as a counter-thesis to that of the apostolic succession of bishops.

Congregationalism stresses the autonomous right of the individual congregation to order its own life in the areas of teaching, worship, polity, and administration. This demand had been raised and practiced by the medieval sects and led to differentiated polities and congregational orders among the Waldenses, the Hussites, and the Bohemian Brethren. Congregationalism was advanced in the Reformation period by the most diverse parties in a renewed and reinforced way not only by "Enthusiasts" (or, in German, Schwärmer) and Anabaptists, who claimed for themselves the right to shape their congregational life according to the model of the original church, but also by individual representatives of Reformation sovereigns, such as Franz Lambert (François Lambert d'Avignon), whose resolutions at the Homberg Synod of 1526 were not carried out because of a veto by Luther. The beginnings of modern Congregationalism probably lie among the English refugee communities on the European mainland, in which the principle of the established church was first replaced by the concept of a covenant sealed between God or Jesus Christ and the individual or the individual congregation.

The basic concepts of Congregationalism

The basic concepts of Congregationalism are: the understanding of the congregation as the "holy people" under the regent Jesus Christ; the spiritual priesthood, kingship, and prophethood of every believer and the exchange of spiritual experiences between them, as well as the introduction of a strict church discipline exercised by the congregation itself; the equal rank of all clergy; the freedom of proclamation of the gospel from every episcopal or official permission; and performance of the sacraments according to the institution of Jesus. By virtue of the freedom of self-determination fundamentally granted every congregation, no dogmatic or constitutional union but rather only county union of the Congregationalist churches developed in England. North America, however, became the classic land of Congregationalism as a result of the great Puritan immigration to New England, beginning with the Pilgrims on the *Mayflower* (1620). In the 20th century, acknowledgement of the full authority of the individual congregation runs through almost all Protestant denominations in the United States and is even found among the Lutherans. Congregationalism participates in the ecumenical movement, within which it presses for awakening the independent activity of the Christian churches in the entire world in terms of a proto-Christian ideal of the congregation.

Numerous other forms of congregational polity have arisen in the history of Christendom, such as the association idea in the Society of Friends. Even Pentecostal communities have not been able to maintain themselves in a state of unrestrained and constant charismatic impulses but instead have had to develop a legally regulated polity. This was what happened in the early church, which likewise was compelled to restrain the freedom of charisma in a system of rulers and laws. Pentecostal communities either have been constituted in the area of a biblical fundamentalism theologically and on the basis of a congregationalist church polity constitutionally or they have ritualized the outpouring of the Spirit itself. Thus, the characteristic dialectic of the Holy Spirit is confirmed: the Spirit creates law and the Spirit breaks law even in the most recent manifestations of its working.

Liturgy. The central focus of the liturgy of the early church was the Eucharist, which the Christian community interpreted as a fellowship meal with the resurrected Christ. Judaism at the time of Christ was dominated by an intense expectation of the Kingdom of God, which would be inaugurated by the Messiah–Son of man. The early Christian Church appropriated this expectation, which revolved around the image of the messianic meal in which the faithful would "sit at table" (Luke 13:29) with the coming Messiah–Son of man. At the centre of Jesus' preaching on the Kingdom of God is the promise that the blessed would "eat bread" with the exalted Messiah–Son of man (Luke 13:29). The Lord himself would serve the chosen community of the Kingdom at the messianic meal (Luke 12:37 ff.), which bears the features of a wedding banquet. The basic mood in the community gathered about him is thus one of nuptial joy over the inauguration of the promised end time, which Jesus emphasized in Matthew, chapter 9, verse 15: "Can the wedding guests mourn as long as the bridegroom is with them?" The supper that Jesus celebrated with his disciples "on the night when he was betrayed" (1 Corinthians 11:23) inaugurated the heavenly meal that will be continued in the Kingdom of God. Decisive for understanding the original meaning of the Eucharist are the words of Jesus in Matthew, chapter 26, verse 29: "I shall not drink again of this fruit of the vine until that day when I drink it new with you in my Father's kingdom."

The image of the messianic meal

The death of Jesus at first bewildered his community in the face of his promise, but the appearances of the Resurrected One, beginning with Easter morning, confirmed their expectations about the messianic Kingdom. These appearances influenced the expectations about the messianic meal and the continuation of fellowship with the exalted Son of man in the meal. Faith in the Resurrection and an expectation of the continuation of the fellowship meal with the exalted Son of man are two basic elements of the Eucharist that are a part of the liturgy from the beginnings of the church. In meeting the Resurrected One in the eucharistic meal the community sees all the glowing expectations of salvation confirmed.

The basic mood of the Eucharist

The basic mood of the community at the eucharistic meal is thereby one of joy. "And breaking bread in their homes, they partook of food with glad and generous hearts, praising God" (Acts 2:46). The Orthodox liturgy has maintained this original Christian mood of joy as at a wedding feast until the present. In Reformation churches, however, a mood of repentance and sorrow over sin often diminished and suppressed the original Christian attitude of joy.

What the Christian community experiences in the eucharistic meal is basically a continuation of the appearances of the Resurrected One in its midst. Thus, many liturgical forms developed, all of which served to enhance the mystery of the eucharistic meal. In the magnificent liturgical creations from the 1st to the 6th century, diversity rather than uniformity was a commanding feature of the development of worship forms. The eucharistic mystery developed from a simple form, as depicted in the 1st-century *Didachē*, to the fully developed liturgies of the 5th and 6th centuries in both the East and the West.

This diversity that was demonstrated in the liturgies of the early church is still preserved in the Clementine liturgy (Antioch), the Syrian liturgy, the Liturgy of St. James of the church of Jerusalem, the Nestorian liturgy in Iran, the Liturgy of St. Mark in Egypt, the Roman mass, the Gallic liturgies, and the Ambrosian (Milanese), Mozarabic (Spanish), and Scottish-Irish (Celtic) liturgies.

In the 6th century two types of liturgies were fixed by canon law in the Eastern Orthodox Church: the Liturgy of St. John Chrysostom (originally the liturgy of Constantinople) and the Liturgy of St. Basil (originally the liturgy of the Cappadocian monasteries). The Liturgy of St. Basil, however, is celebrated only 10 times during the year, whereas the Liturgy of St. John Chrysostom is celebrated most other times. In addition to these liturgies is the so-called Liturgy of the Preconsecrated Offerings, attributed to Pope Gregory I the Great of the 6th century. In this liturgy no consecration of the eucharistic offering occurs—because the eucharistic offerings used have been consecrated on the previous Sunday—and it is celebrated on weekday mornings during Lent as well as from Monday to Wednesday during Holy Week.

The period of liturgical improvisation apparently was concluded earlier in the Latin West than in the East. The liturgy of the ancient Latin Church is textually available only since the 6th century. Though the Gallic liturgies are essentially closer to the Eastern liturgies, the liturgy of Rome followed a special development. From the middle of the 4th century, the Roman mass was celebrated in Latin rather than in Greek, which had been the earlier practice. The fixing of the Roman mass by canon law is congruent with the historical impulse of the Roman Catholic Church to follow the ancient Roman pattern of rendering sacred observance in legal forms and with stipulated regularities.

The tendency of liturgies to become fixed in form

Because of the authority inhering in the sacred, every liturgy has the tendency to become fixed in form, and any alteration of the liturgy can thus be regarded as a sacrilege. The spiritual–legal fixation of the liturgy, however, through the process of constant repetition and habit, led to an externalization that can transfer the liturgy into a lifeless formalism for both the liturgist and the participating community.

Characteristically, all reformation eras in the history of Christianity, in which new charismatic impulses arise in the areas of piety and theology, are also periods of new liturgical creations. Thus in the late 16th-century Reformation a great diversity of new liturgical forms emerged. Luther in Germany restricted himself to a reformatory alteration of the Roman Catholic liturgy of the mass, whereas Zwingli in Switzerland attempted to create a completely new evangelical liturgy of the Eucharist based upon a New Testament foundation. The Free churches also showed a strong liturgical productivity; in the Herrnhut Brethren (Moravian) community, Graf von Zinzendorf ushered in the singing worship services. Methodism, influenced by the Moravian spiritual songs and melodies, also produced new liturgical impulses, especially through its creation of new hymns and songs and its joyousness in singing.

The innovative religious bodies, especially those that arose in the 19th and 20th centuries, have been especially productive in this area. The Mormons, for example, developed not only a new type of church song but also a new style of church music in the context of their liturgical new creation (*e.g.*, "sealing"). The mood of charismatic, liturgical new creations has also been preserved in the Baptist churches of American blacks, whose spirituals are the most impressive sign of a free and spontaneous liturgy. The Pentecostal churches of the 20th century quite consciously attempt to protect themselves against liturgical formalism. The free, often spontaneously improvised liturgy of the Pentecostal tent missions was transformed into patterns that became familiar to a wider audience through televised evangelism, which was often of a Pentecostal nature. Often ecstatic, strongly rhythmized music endeavours to retain certain features of the charismatic spontaneity of the early Christian worship.

Traditional liturgy fixed by canon law, which could develop into a lifeless formalism, occasionally led to the adoption of a fundamentally anti-liturgical attitude. Zwingli's reformation, for example, exhibited an emphatically anti-liturgical tendency in that it reduced the intricate Roman Catholic order of service to beginning song, prayer, sermon, concluding prayer, and concluding song. In many Reformed churches, some anti-liturgical currents developed, which, in terms of visual art, have been directed against encouraging expressions that might distract from the preached and prayed Word. In more radical instances this has even meant protests against the use of the organ in the worship service. The Society of Friends radically eliminated the liturgy and replaced it with mutual silence, expecting the spontaneous activity of the Holy Spirit.

Though definite and obligatory liturgies have been established as normative, the forms of the liturgy continue to develop and change. The impulse toward variations in worship services has been especially noticeable in the latter part of the 20th century. In the Eastern Orthodox liturgy, in the Roman Catholic mass and breviary, and in Anglican and Lutheran liturgies, there are both fixed and changing sections. The fixed parts represent the basic structure of the worship service concerned, and the alternating parts emphasize the individual character of a particular service for a certain day or period of the church year. The changing parts consist of special Old and New Testament readings that are appropriate for a particular church festival, as well as of special prayers and particular hymns.

The basic parts of the eucharistic liturgy

The eucharistic liturgy consists of two parts: the Liturgy of the Catechumens and the Liturgy of the Faithful. This basic liturgical structure goes back to a time in which the church was a missionary church that grew for the most part through conversion of adults. The latter were first introduced to the Christian mysteries as catechumens through instruction in religious doctrine. They also received permission to take part in the first part of the worship service (which was instructional), but they had to leave the service before the eucharistic mystery was celebrated. The first part of the Orthodox worship service still ends with a threefold exclamation, reminiscent of pre-Christian, Hellenistic mystery formulas: "You catechumens, go forth! None of the catechumens (may remain here)!"

The eucharistic liturgy of the Orthodox Church is a kind of mystery drama in which the advent of the Lord is mystically consummated and the entire history of salvation—the incarnation, death, and Resurrection of Christ the Logos, up to the outpouring of the Holy Sprit—is recapitulated. The Orthodox Church also attaches the greatest value to the fact that within the eucharistic mystery an actual transformation of the eucharistic elements in bread and wine takes place. This is not the same as the Roman Catholic dogma of transubstantiation, which teaches that the substance of the bread and wine is changed into the body and blood of Christ, though the properties of the elements remain the same, when the priest consecrates the bread and wine. According to some Orthodox authorities, the Orthodox view is similar to the Lutheran doctrine of the Real Presence. The essential and central happening in the Orthodox liturgy, however, is the descent of the resurrected Lord himself, who enters the community as "the

King of the universe, borne along invisibly above spears by the angelic hosts." The transformation of the elements is, therefore, the immediate emanation of this personal presence. Thus, the Orthodox Church does not preserve and display the consecrated host after and outside the eucharistic liturgy, as in the Roman Catholic Church, because the consecrated offerings are mystically apprehended and actualized only during the eucharistic meal.

In the Roman Catholic mass, the sacrificial character of the Eucharist is strongly emphasized, but it is less so in the Orthodox liturgy. This is because in the Orthodox liturgy the Eucharist is not only a representation of the crucifixion sacrifice (as in the Roman mass) but also of the entire history of salvation, in which the entire congregation, priest and laity, participates. Thus, the Orthodox Church has also held fast to the original form of Holy Communion in both kinds.

The Orthodox Church still preserves the liturgical gestures of the early church. Though in many Protestant churches parishioners sit while praying, the Orthodox worshiper prays while standing (because he stands throughout the service), with arms hanging down, crossing himself at the beginning and ending of the prayer.

Forms of liturgical gestures

The prayerful gesture of folded hands among Protestant churches derives from an old Germanic tradition of holding the sword hand with the left hand, which symbolizes one's giving himself over to the protection of God because he is now defenseless. The prayerful gesture of hands pressed flat against one another with the fingertips pointed upward—the symbol of the flame—is practiced among Roman Catholics as well as Hindus and Buddhists. Other liturgical gestures found in many Christian churches are crossing oneself, genuflecting, beating oneself on the chest, and kneeling during prayer or when receiving the eucharistic elements. Among some Holiness or Pentecostal churches spontaneous handclapping and rhythmic movements of the body have been stylized gestures in the worship services. These gestures are often familiar features of worship in churches in Africa, Asia, and Latin America. Liturgical dancing, widely spread in pagan cults, was not practiced in the early church; vestigial remnants of this ancient practice, however, have been admitted in liturgical processionals. In the latter part of the 20th century, liturgical dances have been reintroduced in some churches but only in a limited fashion. Among the many other gestures of devotion and veneration practiced in the liturgically oriented churches such as the Roman Catholic Church, the High Church Anglican churches, and the Orthodox Church, are kissing the altar, the gospel, the cross, and the holy icons.

Liturgical vestments have developed in a variety of fashions, some of which have become very ornate. The liturgical vestments all have symbolic meaning (see below *Church year: Liturgical colours*). In the Orthodox Church the liturgical vestments symbolize the wedding garments that enable the liturgists to share in the heavenly wedding feast, the Eucharist. The *epitrachēlion,* which is worn around the neck and corresponds to the Roman stole, represents the flowing downward of the Holy Spirit (see also RITES AND CEREMONIES, SACRED).

The sacraments. The interpretation and number of the sacraments vary among the Roman Catholic, Orthodox, Eastern independent, and Protestant churches. The Roman Church has fixed the number of sacraments at seven: baptism, confirmation, the Eucharist, penance, holy orders, matrimony, and anointing of the sick. In the early church the number of sacraments varied, sometimes including as many as 10 or 12. The theology of the Orthodox Church, under the influence of the Roman Catholic Church, fixed the number of sacraments at seven. The classical Protestant churches (*i.e.,* Lutheran, Anglican, and Reformed) have accepted only two sacraments—*i.e.,* baptism and the Eucharist, though Luther allowed that penance was a valid part of sacramental theology.

The number of sacraments and forms of sacramentals

The New Testament mentions a series of "holy acts" that are not, strictly speaking, sacraments. Though the Roman Catholic Church recognizes a difference between such "holy acts," which are called sacramentals, and sacraments, the Orthodox Church does not, in principle, make such strict distinctions. Thus, though baptism and the Eucharist have been established as sacraments of the church, foot washing, which in the Gospel According to John, chapter 13, replaces the Lord's Supper, was not maintained as a sacrament. It is still practiced on special occasions, such as on Holy Thursday in the Roman Catholic Church and as a rite prior to the observance of the Lord's Supper, as in the Church of the Brethren. The "holy acts" of the Orthodox Church are symbolically connected to its most important mysteries. Hence, baptism consists of a triple immersion that is connected with a triple renunciation of Satan that the candidates say and act out symbolically prior to the immersions. Candidates first face west, which is the symbolic direction of the Antichrist, spit three times to symbolize their renunciation of Satan, and then face east, the symbolic direction of Christ, the sun of righteousness. Immediately following baptism, chrismation (anointing with consecrated oil) takes place, and the baptized believers receive the "seal of the gift of the Holy Spirit."

Tradition. The disposition of Christianity toward tradition has exhibited a characteristic tension from its very beginnings; it has broken tradition and it has created tradition. This tension, which is grounded in its essence, has been continued throughout its entire history. It began with breaking the tradition of piety described and prescribed in the Hebrew Scriptures and synagogue practices, which to the followers of Jesus looked legalistic. In the Sermon on the Mount, Jesus set forth his message as a renunciation of the Old Testament tradition of the Law. Yet, with his coming, new revelation, life, death, and Resurrection, he himself created a new tradition, a "new law," that has been carried on in the church. The dogmatic controversies of the Reformation period give the impression that the tradition of the church has to do primarily, if not exclusively, with ecclesiastical doctrinal tradition. Tradition, however, includes all areas of life of the Christian community and its piety, not just the teachings but also the forms of worship service, bodily gestures of prayer and the liturgy, oral and written tradition and the characteristic process of transition of the oral into written tradition, a new church tradition of rules for eating and fasting, and other aspects of the Christian life.

The inherent tension regarding tradition in Christianity

The break with the tradition of Jewish legal piety was not total. The Old Testament was adopted from Jewish tradition, but its interpretation was based upon the concepts of salvation that emerged around the figure of Jesus Christ. The Old Testament book of Psalms, including its musical form, was taken over in Christian worship as the foundation of the liturgy. The new revelation became tradition in the oral transmission of the words of the Lord (the logia) and the reports (kerygma) concerning the events of his life that were important for the early church's faith in him; his baptism, the story of his Passion, his Resurrection, and his Ascension. The celebration of the Lord's Supper as anticipation of the heavenly meal with the Messiah–Son of man in the coming Kingdom of God, even to the point of preserving in the liturgy the Aramaic exclamation *maranatha* ("O Lord, Come") and its Greek parallel *erche kyrie* ("Come, Lord!") as the supplicant calling for the Parousia (Second Coming)—all this became tradition.

In addition to the traditions of the Old Testament synagogal worship service, traditions of the Hellenistic mystery cults also were absorbed and reinterpreted in Christian forms. Among the traditions taken over from the mystery religions were: the arcane discipline—the distinction between the true *mystae* (those initiated into the secrets of the Christian faith), who were permitted to participate in the esoteric worship service (*i.e.,* the Eucharist), and the catechumens; the introduction of hymn singing dependent upon the melodic style of the mystery hymns (in addition to the Jewish Psalms); the retention of the ancient gesture of upraised hands during the epiclesis, the prayer that calls down the Holy Spirit upon bread and wine as they are consecrated in the sacrament; and many others.

Oral and written tradition

Of special significance is the oral tradition of doctrinal transmission and its written record. Judaism over the centuries had developed its own unique tradition of the oral transmission of teachings. According to rabbinic doctrine,

orally transmitted tradition coexisted on an equal basis with the recorded Law. Both text and tradition were believed to have been entrusted to Moses on Mount Sinai. Within the unbroken chain of scribes the tradition was passed on from generation to generation and substantiated through scripture and exegesis. The doctrinal contents of the tradition were initially passed on orally and memorized by the students through repetition. Because of the possibilities of error in a purely oral transmission, however, the extensive and growing body of tradition was, by necessity, fixed in written form. The rabbinic tradition of the Pharisees (a Jewish sect that sanctioned the reinterpretation of the Mosaic Law) was established in the Mishnah (commentaries) and later in the Palestinian and Babylonian Talmud (compendiums of Jewish Law, lore, and commentary). Because the essence of tradition is never concluded—*i.e.,* by its very nature is never completely fixed in writing—the learned discussion of tradition by necessity continued in constant exegetical debate with the Holy Scriptures. The written record of tradition, however, never claimed to be equal to the Holy Scriptures in Judaism. A similar process of written fixation also occurred among the sectarians of the community at Qumrān, which in its *Manual of Discipline* and in the *Damascus Document* recorded its interpretation of the Law, developed first orally in the tradition.

In the Christian Church a tradition also was formed proceeding from Jesus himself. The oral doctrinal transmission of the tradition was written down between the end of the 1st and the first half of the 2nd century in the form of various gospels, histories of the Apostles, letters, sermonic literature, and apocalypses. Among Christian Gnostics the tradition also included secret communications of the risen Christ to his disciples.

A new element, however, inhered in the Christian vis-à-vis the Jewish tradition. For Jewish piety the divine revelation encompassed two forms of divine expression: the Law and the Prophets. Nevertheless, this revelation is considered concluded with the last Prophets; its actualization further ensues through interpretation. In the Christian Church the tradition is joined not only to the teachings of Jesus and the story of his life as prophet and teacher that terminated with his death but also to the central event of the history of salvation, which his life, Passion, death, and Resurrection represent—namely, to the resurrected Christ who is henceforth present as the living Lord of the church and guides and increases it through his Holy Spirit. This led to the literary form of church tradition—the Holy Scripture. As the "New Testament," it takes its place next to the Holy Scripture of Judaism, henceforth reinterpreted as the "Old Testament." The tradition of the church itself thereby entered into the characteristic Christian tension between spirit and letter. The spirit creates tradition but also breaks tradition as soon as the latter is solidified into an external written form and thus impedes charismatic life.

The role of kerygma in tradition

Throughout church history, however, the core of this field of tension is formed by the transmission of the Christ event—the kerygma—itself. On the one hand, the kerygma is the bearer and starting point for tradition; on the other hand, it molds the impetus for ever-new impulses toward charismatic, fresh interpretations and, under certain circumstances, suggests or even enforces a conscious elimination of accumulated traditions. Decisive in this respect is the self-understanding of the church. According to the self-understanding of the Roman Catholic and the Eastern Orthodox churches, the church, as the institution of Jesus Christ, is the bearer of the oral and the written tradition. It is the church that created the New Testament canon. The selection of canonical writings undertaken by it already presupposes a dogmatic distinction between "ecclesiastical" teachings—which, in the opinion of its responsible leaders, are "apostolic"—and "heretical" teachings. It thereby already presupposes a far-reaching intellectualization of the tradition and its identification with "doctrine." The oral tradition thus became formalized in fixed creedal formulas.

Accordingly, in the history of the Christian Church a specific, characteristic dialectic has been evidenced between periods of excessive growth and formalistic hardening of tradition that hindered and smothered the charismatic life of the church and periods of a reduction of tradition that follow new reformational movements. The latter occurred, in part, within the church itself, such as in the reforms of Cluny, the Franciscans, and the Dominicans; they also took on the form of revolutionary movements. The Reformation of the 16th century exhibited various degrees of positions toward tradition. All of the Reformers broke with the institution of monasticism, the liturgical and sacramental tradition of the Roman Catholic Church, and certain elements of doctrinal tradition. Luther, however, was more conservative in his attitude toward the Roman Catholic Church than were Zwingli and Calvin. He was thus especially hated among the representatives of the radical Reformation—*e.g.,* the Anabaptists and Enthusiasts (Schwärmer), who demanded and practiced a revolutionary break with the entire Roman Catholic tradition. The new churches that arose from the Reformation, however, soon created their own new traditions. This was made necessary by the predominance of both the didactic, doctrinaire principle and the founding of one's own church upon one's own "confessional writings." Practical manifestations against the tradition of the Roman Catholic Church also had public effects—*e.g.,* the eating of sausage on fast days in Zürich at the start of Zwingli's reformation or the provocative marriages of monks and nuns.

The Reformation view of tradition

In the 19th century, the period of a progressive revolutionizing of political life in Europe and North and South America, the Roman Catholic Church sought to safeguard its tradition—threatened on all sides—through an emphatic program of "antimodernism." It endeavoured to protect tradition both by law and through theology (*e.g.,* in returning to a strict, obligatory neo-Thomism). The representatives of this development were the popes from Pius IX (reigned 1846–78) to Pius XII (reigned 1939–58). With Pope John XXIII (reigned 1958–63), a dismantling (*aggiornamento*) of antimodernism and a more critical attitude vis-à-vis the "tradition" set in; this extended to traditional dogmatic views as well as to the liturgy and church structure. The second Vatican Council (1962–65) guided this development into moderate channels. On the other hand, an opposite development has taken place in the Soviet Union and the eastern European countries. In these nations the remains of the Orthodox Church, which survived extermination campaigns of the Leninist and Stalinist eras from the 1920s to the 1950s, preserved themselves in a political environment hostile to the church precisely through a retreat to their church tradition and religious functioning in the realm of the liturgy. In the World Council of Churches, the Orthodox Church in the latter part of the 20th century has viewed its task as the bearer of Christian tradition over against the predominant social-ethical tendencies of certain Protestant member churches that have disregarded or de-emphasized the tradition of the church in a wave of antihistorical sentiment.

The role of exegesis in scriptural traditions

The most important creation of church tradition is that of the Holy Scriptures themselves and, secondarily, the exegesis (critical interpretations and explanations) of the Scriptures. Exegesis first appeared in Christian circles among Gnostic heretics and the church catechists (teachers)—*e.g.,* in the Christian school systems, such as in Alexandria and Antioch. The heretics, who could not claim the unbroken apostolic tradition maintained by the Orthodox Christian churches, had a necessary interest in claiming the tradition to justify their own movements. Thus, exegesis was directly related to the development of a normative scriptural canon in the Orthodox churches. A similar need for the interpretation of an ecclesiastically fixed scriptural canon resulted in the Christian school system.

The first representatives of early church exegesis were not the bishops but rather the "teachers" (*didaskaloi*) of the catechetical schools, modeled after the Hellenistic philosophers' schools in which interpretive and philological principles had been developed according to the traditions of the founders of the respective schools. The allegorical interpretation of Greek classical philosophical and poetical texts, which was prevalent at the Library and Museum (the school) of Alexandria, for example, directly influenced

the exegetical method of the Christian Catechetical school there. Basing his principles on the methods of Philo of Alexandria and Clement of Alexandria, his teacher, and others, Origen—the Christian Catechetical school's most significant representative—created the foundation for the type of Christian exegesis (*i.e.,* the typological-allegorical method) that lasted from the patristic period and the Middle Ages up to the time of Luther in the 16th century. Origen based his exegesis upon comprehensive textual-critical work that was common to current Hellenistic practices, such as collecting Hebrew texts and Greek parallel translations of the Old Testament. His main concern, however, was that of ascertaining the spiritual meaning of the Scriptures, the trans-historical divine truth that is hidden in the records of the history of salvation in the Scriptures. He thus developed a system containing four types of interpretation: literal, moral, typological, and allegorical.

The view of "teachers" as charismatic figures (*i.e.,* those gifted by the Holy Spirit with the ability to uncover the hidden spiritual meaning of the letter) long hindered Western theologians in developing their own exegetical works. Exegetical literature was restricted to "chains" (*catenae*), in which excerpts from commentaries or homilies of the charismatic Fathers were joined together in a "chain" for the individual words and sentences of the Holy Scriptures. This was similar to the way in which early medieval theological works were composed of "sentences"—*i.e.,* individual doctrinal definitions from the writings of authoritative church teachers along with a limited commentary. Typological exegesis attained special significance for medieval Christian mysticism, which was inspired to a great extent by the allegorical interpretation of the Song of Solomon as the wedding between Christ and the soul.

The exegetical principles of the Reformation

Only with the Reformation, under the leadership of Luther, did there emerge an emphatic turning away from the allegorical exegesis and a turning toward the literal meaning of the Scriptures. This had its beginnings in the early church in the theological school of Antioch. In contrast to the Platonic tradition of the school of Alexandria, the school of Antioch was guided by Aristotelian philosophy. In place of allegorizing, which was consciously rejected, Antiochene exegesis was very much occupied with textual criticism. Both traditions often were included together in the so-called glosses of the Latin Middle Ages, such as in the *Glossa ordinaria* ("Ordinary Glosses"), edited by Anselm of Laon (died 1117), and the *Postillae*—the first biblical commentary to be printed (1471–72)—of Nicholas of Lyra (*c.* 1270–1349).

According to his own statement, Luther's reformational breakthrough came about through a fresh exegetical reflection—*legendo et docendo* ("by perusing and teaching")—in connection with his lectures on the Bible at the university of Wittenberg in Germany. He used the preliminary work of humanist philologists for the restoration of the Old and New Testament text (*e.g.,* Erasmus' 1516 edition of the Greek New Testament in the lectures on the Letter of Paul to the Romans). Luther replaced the traditional schema of the fourfold meaning of the Scripture with a spiritual interpretation of the letter—*i.e.,* one based on Christ. Inasmuch as the letter, which speaks historically of the work of Christ, at the same time always means this work as the salvation event that has happened "for us," it always contains the spiritual meaning in itself. In debates with the Spiritualists and Enthusiasts, who made use of the allegorical-tropological (figurative) method, Luther appealed ever more strongly to the unequivocal "clarity" of the letter of the Scriptures, which contains the "clarity" of the "subject" expressed by it. His exegesis is thus also a dogmatic one. The struggle between historical and tropological exegesis was emphasized in the debate between Luther and Zwingli over the understanding of the Lord's Supper.

During the early 18th century, biblical interpretation free of dogmatic interest was achieved among theologians accused of heresy by orthodox colleagues of their confession, such as among the Dutch Arminians (*e.g.,* Hugo Grotius and Johann Jakob Wettstein). Interest in the history of the Old and New Testament period was growing; ancient Middle Eastern history, biblical geography and archaeology, and the history of the religions of the ancient East and Hellenism were being included in the interpretation of the Scriptures. Under the influence of the Enlightenment, the historical criticism of the Bible, which was independent of the moral and edifying evaluation of the Holy Scriptures, was established. Soon including criticism of early church dogma, it led directly to the rise of historical criticism of the Bible in the 19th and 20th centuries.

Development of historical criticism of the Bible

In addition to the tradition of the Holy Scriptures and its interpretation, traditions centring on holy places also developed. The veneration of holy places is the oldest expression of Christian popular piety. From Judaism the Christian Church adopted the idea and practice of venerating holy places. In post-exilic Judaism (*i.e.,* after the 5th century BC), Jerusalem became the sanctuary and the centre of the Jews in Palestine as well as the goal of the pilgrimages of Jews of the Diaspora. After the destruction in AD 70 of Jerusalem, which was the holy city for the early church, it remained for Christians—as the site of the suffering and Resurrection of Jesus Christ and as the place of his return in glory—a holy city and a goal of pilgrimages. Such early bishops as Melito of Sardis and Alexander of Jerusalem and such theologians as Origen embarked on pilgrimages to Jerusalem. When the Christian Church became the state church in the 4th century, pilgrimages to the holy places in Palestine became popular.

The journey of the empress mother Helena to the Holy Land before AD 330 inaugurated the cult of relics through the alleged discovery of the holy cross. Constantine built the Church of the Holy Sepulchre in Jerusalem (335) and the Church of the Nativity over the Grotto of the Nativity in Bethlehem. The numerous other biblical commemorative places of the Old and New Testament history soon followed.

The cult of martyrs and saints led to establishment of shrines outside Palestine that were developed into pilgrimage places. The idea that the martyrs are present at the places of their martyrdom (*e.g.,* Peter's tomb at the Vatican) secured a prominent position for holy places connected with the cult of saints and martyrs. The cult of the martyrs was developed especially in the Roman catacombs, and it contributed to the formation of the Petrine doctrine and the teaching of the primacy of the Roman bishop. After the 4th century the cult of martyrs spread further and created an abundance of new holy places in the West: thus, Santiago de Compostela in Spain was connected with the tomb of James, to which equal rank with Rome and Jerusalem was later accorded; then Trèves in Germany, with the tomb of Matthew, which exerted a special power of attraction through the relic of the holy robe; and Marburg in Germany, with the shrine of St. Elizabeth. In the Middle Ages, during the development of the Roman Catholic sacrament of penance, holy places became places of grace, the visitation of which was considered a work of penance.

The veneration of relics

The original historical consciousness of the Christian Church is also alive in the cult of relics. In the relics of the body in which the saint suffered martyrdom, the saint himself is believed to be present, or at least something of the power of the Holy Spirit that filled him. The cult of relics began as a result of veneration of a martyr at his or her tomb, over which later was erected an altar of the church built to honour the saint. From the 4th century on in the East, and later also in the West, the remains of the martyrs were distributed in order that as many as possible could share in their miraculous power. Fragments of relics were sewn into a silken cloth (antimension), and the Eucharist could be celebrated only upon an altar that was covered with such an antimension. In times of persecution the Eucharist could be celebrated upon any table, as long as it was covered with the antimension and consecrated through the presence of the martyr. In the Latin Church the relics are enclosed in a cavity (*sepulcrum*) in the altar top. During the deconsecration of a church, the relic is again removed from the *sepulcrum*.

In the late Middles Ages the character of the pilgrimage, just like the veneration of relics, underwent a degeneration in connection with the degeneration of the sacrament of penance because of the abuse of the indulgence.

Luther's critique of the indulgence began with a criticism of the display of the elector of Saxony Frederick III the Wise's imposing collection of relics in the Schlosskirche (Castle Church) of Wittenberg on All Saints' Day (1516). Over against the attacks of Luther, the Council of Trent declared that

> the holy bodies of the holy martyrs and others living with Christ, whose bodies were living members of Christ and temples of the Holy Spirit, and will be by him raised to eternal life and glorified, are to be venerated by the faithful, since by them God bestows many benefits upon men.

In order to avoid the development of a holy place at his grave and a reliquary and saintly cult around his person, Calvin arranged by will that his body be buried at an unknown spot. The erection of the giant monument to the Reformer at the supposed place of his burial shows the futility of his effort and the strength of the Christian consciousness of tradition.

The roots, ideals, and purposes of monasticism

Monasticism. Monasticism, an institution based on the Christian ideal of perfection, has its roots in New Testament Christianity, in which the baptized were designated as the "perfect ones." In the early church, monasticism equated perfection with world-denying asceticism, along with the view that perfect Christianity centred its way of life on the maximum love of God and neighbour.

Monastic discipline, in the course of time, became an external means for the attainment of this ideal of perfect love of God and neighbour. Only a few especially disciplined persons, however, have been able to live according to the path that leads to the ideal of perfection. The masses, on the other hand, are inwardly and outwardly incapable of exercising ascetic discipline. Therefore, the monastic rules of life were not generally binding "commands" but rather only "counsels" directed to those called to lead an ascetic life. The essential distinction between command and counsel is found in the words of Jesus: he did not command men to "make themselves eunuchs for the sake of the kingdom of heaven," but rather he recommended this condition only to those who were "able to receive this" (Matthew 19:12). Unmarried ascetics were recognized as a special class in the early church, forming the core of many churches. Later, with its distinction between counsel (*suasum*) and command (*iussum*), as in the writings of Tertullian in the late 2nd century, the church found itself in full accord with the oldest Christian view. During the latter part of the 2nd and the beginning of the 3rd century, the combination of asceticism and mysticism, which was to become the spiritual basis of later monasticism in the East and in part also in the West, was emphasized by Clement of Alexandria and Origen.

By the 4th century, monasticism had become an established institution in the Christian Church. This was not because of the decadence of the people of late antiquity, as has often been asserted, but rather because monasticism was sustained by the resilient and culturally unexhausted rural populations of Egypt and Syria, who had developed an enthusiasm for asceticism itself. Out of the desire for still further advanced isolation, ascetics moved from areas in proximity to inhabited places and established themselves in tombs, abandoned and half-deteriorated human settlements, caves, and, finally, into the wilderness areas of the deserts. The main task of the ascetics—*i.e.,* struggle with the demons—thereby underwent a heightened intensification: the desert was considered the abode of the demons, the place of refuge of the pagan gods falling back before a victorious Christianity. Hence, the expansion of Christianity in the cities of Egypt and the rise of Egyptian desert monasticism in the 4th century occurred both because the masses streamed into the churches as a result of the official imperial toleration and support policies and because ascetics striving for perfection left the cities and moved into the desert in significant numbers.

The influence of the monastic leaders

Certain writings that captured the spirit of monasticism further enhanced the development of this way of life in the church. Athanasius of Alexandria, the 4th century's most significant bishop spiritually and in terms of ecclesiastical politics, wrote the *Life of St. Antony,* which described the eremitic (hermit) life in the desert and the awesome struggle of ascetics with the demons as the model of the life of Christian perfection. This work indicates that the church sanctioned and propagated monasticism.

A former Roman soldier of the 4th century, Pachomius, created the first monastery in the modern sense. He united the monks under one roof in a community living under the leadership of an abbot (father, or leader). In 323 he founded the first true monastic cloister in Tabennisi, north of Thebes, in Egypt, and joined together houses of 30 to 40 monks, each with its own superior. Pachomius also created a monastic rule that, however, served more as a regulation of external monastic life than spiritual guidance. During the remainder of the 4th century, monasticism soon developed in areas outside Egypt. Athanasius brought the monastic rule of Pachomius to the West during his banishment (340–346) to Trèves in Germany—as a result of his opposition to the imperially sanctioned heretical doctrines of Arianism. Mar Awgin, a Syrian monk, introduced the monastic rule in Mesopotamia, and Jerome established a monastic cloister in Bethlehem.

Basil the Great, one of the three Cappadocian Fathers of the 4th century, definitively shaped monastic community life in the Byzantine Church. His ascetic writings furnished the theological and instructional foundation for the "common life" (cenobitism) of monks. He became the creator of a monastic rule that, through constant variations and modifications, became authoritative for later Orthodox monasticism. The Rule of Basil has preserved the Orthodox combination of asceticism and mysticism into the 20th century.

The development of Western monasticism

Western monasticism, founded by Benedict of Nursia (Italy) in the 6th century, has gone through a double form of special development vis-à-vis early church monasticism. The first consists of its clericalization. In modern Roman Catholic cloisters, monks are, except for the serving brothers (*fratres*), ordained priests and are thereby drawn in a direct way into the ecclesiastical tasks of the Roman Church. Originally, however, monks were laymen. Pachomius had explicitly forbidden monks to become priests on the ground that "it is good not to covet power and glory." Basil the Great, however, by means of a special vow and a special ceremony, enabled monks to cease being just laymen and to attain a position between that of the clergy and the laity. Even in the 20th century, monks of the Orthodox Church are, for the most part, lay monks; only a few fathers (abbots) of each cloister are ordained priests (*hieromonachoi*), who are thus allowed to administer the sacraments.

The second special development in Roman Catholicism consists of the functional characteristics of its many orders. The individual orders aid the church in its various areas of activity—*e.g.,* missions, education, care for the sick and needy, and combating heresy. Developing a wide-ranging diversification in its structure and sociological interests, Roman Catholic monasticism has extended all the way from the knightly orders to orders of mendicant friars, and it has included orders of decided feudal and aristocratic characteristics alongside orders of purely bourgeois characteristics. To the degree that special missionary, pedagogical, scholarly-theological, and ecclesiastically political tasks of the orders increased in the West, the character of ancient monasticism—originally focused completely on prayer, meditation, and contemplation—receded more and more in importance. Few monastic orders—the Benedictines and the Carmelites are notable exceptions—still attempt to preserve the ancient character and purposes of monasticism in Roman Catholicism in the 20th century.

The meaning of "saint"

The saintly life. In Christian popular piety the saint plays a very significant role. Originally a self-designation of all Christians collectively, "the saints," understood in this broad sense, are "sanctified through the name of the Lord Jesus Christ and through the Spirit of our God," according to the First Letter of Paul to the Corinthians, chapter 1, verse 31. On the one hand, the saint may be understood as a Christian who endeavours to fulfill the binding demand of moral holiness in obedience to God and in love of his neighbour (2 Corinthians 7:1; 1 Thessalonians 4:3), or a charismatic figure in whom the gifts of the Holy Spirit operate according to the personal and temporal circumstances of such an individual. Because

of certain views on being "called to holiness," members of many radical sects have designated themselves as "the saints"—from Oliver Cromwell's "saints" in 17th-century England to the Mormon "latter-day saints" in the 19th and 20th centuries.

The general meaning of "saint" was transformed during the period of the persecutions of Christians in the Roman Empire. The martyr, the witness in blood to Christ and follower in his suffering, became the prototype of the future ideal of the saint. Veneration of the saints began because of a belief that martyrs were received directly into heaven after their martyrdoms and that their intercession with God was especially effective—in the Revelation to John the martyrs occupy a special position in heaven, immediately under the altar of God (Revelation 6:9). Veneration of confessors (*i.e.,* those who had not denied their belief in Christ but had not been martyred), bishops, popes, early Church Fathers, and ascetics who had led a godlike life was established soon after cessation of the persecutions.

The veneration of saints

In the Greek church the saints were regarded as charismatic figures in whom the prototype of Christ is reflected in multifarious images. Veneration of the saints in the Orthodox churches was thus based more upon the idea that the saints provided instructional examples of the Christian life of sanctification. In the West, however, cultic veneration of the saints, the concept of patron saints, and the view that saints are helpers in need became predominant. The cult of the saints gradually came under the control of the papacy, which regulated cultic veneration of a saintly personality extolled in popular piety by means of a process of canonization strictly defined by canon law. The saints thus dominated the church calendar, which notes the names of the ecclesiastically recognized saints of each day of the year. They are venerated on a particular day in the prayer of intercession, and references are made to their deeds, sufferings, and miracles in the liturgy.

Under Pope Paul VI, the Roman Catholic Church attempted to reduce the significance of the veneration of saints—and thereby emphasize the idea of their historical exemplariness—by deleting some unhistorical, ostensibly mythological figures from the calendar of saints. The difference between historical and mythological saints, however, is difficult to maintain in details because mythological features from pre-Christian hero myths had often been intermixed, even in the lives of demonstrably historical saints. Thus, deletion of saints from the calendar has had little success in popular piety. Pope John Paul II, fully respectful of the directions of the second Vatican Council, did, however, pay renewed respect to some of the pre-council forms of devotion which the reformers had tended to displace.

In the early church the veneration of saints at first was restricted to celebrations at their tombs, but the cult of saintly relics soon spread the veneration of particular saints to many areas. The *Martyrdom of Polycarp,* for example, called the remains of the bishop Polycarp of Smyrna, martyred in 156/167, "more precious than costly stones and more excellent than gold." A belief in the need of special protection by saints is the basis of the system of patron saints: most Roman Catholic churches have a saint as their patron, whose presence in the church is represented by a relic of that particular saint. Saints, however, became patrons not only of churches but also of cities, regions, vocational groups, or classes. Saints also won a special significance as patrons of names: in the Roman Catholic and Eastern Orthodox churches a Christian generally received the name of the saint on whose holiday (day of death) he is baptized. The believer is thus joined for life with the patron of his name through the name and the name day, which, as the day of rebirth (*i.e.,* baptism), is of much greater significance than the natural birthday.

In the Eastern Orthodox Church, relics of saints appear less frequently, but icons of saints appear in greater numbers. Though cultic veneration of saints as patrons, tutelary saints, and helpers in need has increased through the centuries, the view that the saints are examples of the Christian life of sanctification has been preserved. The Roman Catholic Church, through its use of the canonization of saints, has constantly established new models for practical religiosity and morality to meet contemporary needs—raising to the position of sainthood personages all the way from the holy king to the holy servant girl.

Reformation and modern views of saints

In view of the excess of the veneration of saints, the Reformation not only eliminated the cultic veneration of saints but also images and relics of the saints from the churches and homes. Although the Reformation did not theoretically deny the saints their significance as historical witnesses to the power and grace of God, through such radical measures it virtually eliminated the meaning of saints as guiding images and examples of Christian life. Under the influence of Luther's view that all believers are saints, the veneration of the saints and their relics also was either de-emphasized or eliminated. The experience of martyrdom in the times of persecution in the Reformation and Counter-Reformation encouraged the development of a new saintly ideal in the radical Protestant sects in connection with the renewal of a strict demand for sanctification. Such was the case in the Baptists' "Chronicle of the Martyrs" as well as in Spiritualism. The Swedish archbishop Nathan Söderblom's attempt at awakening in Protestantism in the 20th century a new understanding of the saint received notice in Protestant ecumenical circles and led to a rediscovery of saints in the Protestant realm (*e.g.,* through Walter Nigg's book *Great Saints*). In modern Roman Catholicism, emphasis is increasingly being placed upon the charismatic aspects of the saints and their significance as models of a spiritual, holy Christian life.

Art and iconography. Christian art constitutes an essential element of the Christian religion. Until the 17th century the history of Western art was largely identical with the history of Western ecclesiastical and religious art. During the first three centuries of the Christian Church, however, there was no Christian art, and the church generally resisted it with all its might. Clement of Alexandria, for example, criticized religious (pagan) art in that it encouraged people to worship that which is created rather than the Creator. About the mid-3rd century an incipient pictorial art began to be used and accepted in the Christian Church but not without fervent opposition in some congregations. Only when the Christian Church became the Roman imperial church under Emperor Constantine in the early 4th century were pictures used in the churches, and they then began to strike roots in Christian popular religiosity.

Early attitudes concerning the use of religious art

Later, however, when pictorial art was publicly placed in the service of the church, warnings against this development were voiced by leading theologians. The church historian Eusebius, the most diligent glorifier of Constantine, characterized the use of images of the Apostles Paul and Peter as well as of Christ himself as a pagan custom. Asterius, bishop of Amaseia in Pontus during the late 4th and early 5th centuries, similarly stated in a sermon:

> Do not picture Christ on your garments. It is enough that he once suffered the humiliation of dwelling in a human body which of his own accord he assumed for our sakes. So, not upon your robes, but upon your soul, carry about his image.

Epiphanius (*c.* 315–402), bishop of Salamis in Greece, also energetically opposed in word and deed the disposition toward images in the imperial church:

> Have God always in your hearts, but not in the community house, for it does not become a Christian to expect the elation of his soul from recourse to his eyes and the roaming about of his senses.

Christian art developed at such a late stage because of its origins in Judaism and its opposition to paganism and the emperor's cult. In addition to a faith in God the Father, Creator of heaven and Earth, and faith in the uniqueness and holiness of God, Christianity also received from its Jewish origins a prohibition against the use of images to depict the sacred or holy, including humans, who were created in "the image of God." The early Christian Church was also deeply involved in a struggle against paganism, which, to the Christian observer, was viewed as idolatry in that its many gods were represented in various pictorial and statuary forms. In early Christian missionary preaching, the Old Testament attacks upon pagan veneration of images were transferred directly to pagan image veneration of the first three centuries AD. The struggle against

images was conducted as a battle against "idols" with all the intensity of faith in the oneness and exclusiveness of the imageless biblical God.

Abhorrence of images also was furthered because the emperor's cult was so despised by Christians. Christians were compelled, through anti-Christian legislation, to venerate the imperial images by offering sacrifices to them. Refusal to make the sacrifice was the chief cause of martyrdom. Characteristically, thus, the Christian Church's reaction after its public recognition was expressed in the riotous destruction of the pagan divine images.

In spite of these very strong religious and emotional restraints, the church developed a form of art peculiar to its needs. Protestants often have held that the development of ecclesiastical art was a part of the entire process of the inner decay of the Christian Church when it was elevated to the position of the officially favoured religious institution of the Roman Empire. In other words, some groups within Protestantism have claimed that the development of church art was part of the process of the church's inner paganization.

The incarnation as the basis for the use of images

The starting point for the development of Christian pictorial art, however, lies in the basic teaching of the Christian revelation itself—namely, the incarnation, the point at which the Christian proclamation is differentiated from Judaism. The incarnation of the Son of man, the Messiah, in the form of a human being—who was created in the "image of God"—granted theological approval of a sort to the use of images that symbolized Christian truths. Clement of Alexandria, at one point, called God "the Great Artist," who formed humans according to the image of the Logos, the archetypal light of light. The great theological struggles over the use of images within the church during the period of the so-called Iconoclastic Controversy in the 8th and 9th centuries indicate how a new understanding of images emerged on the basis of Christian doctrine. This new understanding was developed into a theology of icons that still prevails in the Eastern Orthodox Church in the 20th century.

The great significance of images of the saints for the Orthodox faithful is primarily expressed in the cultic veneration of the images within the worship service. Second, it is expressed in the dogmatic fixation of the figures, gestures, and colours in Eastern Church iconic art. In the West, the creative achievement of the individual artist is admired, but Orthodox painting dispenses with the predominance of the individual painter's freely creative imagination. Throughout the centuries the Eastern Church has been content with reproducing certain types of holy images, and only seldom does an individual artist play a predominant role within the history of Orthodox Church painting. Most Orthodox ecclesiastical artists have remained anonymous. Icon painting is viewed as a holy skill that is practiced in cloisters in which definite schools of painting have developed. In the schools, traditional principles prevail so much that different artist-monks generally perform only certain functions in the production of a single icon. Style motifs—*e.g.,* composition, impartation of colour, hair and beard fashions, and gestures of the figures—are fixed in painting books that contain the canons of the different monastic schools of icon painters.

The significance of icons in Eastern Orthodoxy

The significance of the image of the saint in the theology, piety, and liturgy of the Eastern Orthodox Church can be judged historically from the fact that the struggle over holy images within Orthodox Church history brought about a movement whose scope and meaning can be compared only with the Reformation of Luther and Calvin. In the 7th century a tendency hostile to images and fostered by both theological and political figures gained ground within the Byzantine Church and upset Orthodox Christendom to its very depths; known as the Iconoclastic Controversy, it was supported by some reform-minded emperors. Although opponents of icons had all the political means of power at their disposal, they were not able to succeed in overthrowing the use of icons. The conclusion of this struggle with the victory of the supporters of the use of icons is celebrated in the entire Orthodox Church on the first Sunday of Lent as the Feast of Orthodoxy.

Orthodox icon painting is not to be separated from its ecclesiastical and liturgical function. The painting of the image is, in fact, a liturgical act in which the artist-monks prepare themselves by fasting, penance, and consecrating the materials necessary for the painting. Before the finished icon is used, it likewise is consecrated. Not viewed as a human work, an icon (according to 8th- and 9th-century literature) was understood instead as a manifestation of a heavenly archetype. A golden background is used on icons to indicate a heavenly perspective. The icon is always painted two-dimensionally because it is viewed as a window through which worshipers can view the heavenly archetype from their earthly position. A figure in the three-dimensionality of the plastic arts, such as sculpture, would thus be an abandonment of the character of epiphany (appearance).

Ideas of the iconic liturgy dominate the manuals of the Orthodox icon painters. The model of the Christ figure for icon painters was found in an apocryphal writing of the early church—the *Letter of Lentulus,* which was a legendary letter supposedly written by a certain Lentulus, who was named consul in the 12th year of the emperor Tiberius. As the superior of Pontius Pilate, the procurator of Judaea, he by chance was staying in Palestine at the time of the trial of Jesus. In an official report to the Emperor about the trial of Jesus, Lentulus included an official warrant for Jesus with a description of the Christ. This apocryphal description furnished the basic model for the Byzantine Christ type.

The Trinity also may not be represented, except in those forms in which, according to the view of Orthodox church doctrine, the Trinity showed itself in the divine Word of the Old and New Testaments. Early church theology interpreted an Old Testament passage (Genesis 18:1 ff.) as an appearance of the divine Trinity—namely, the visit of the three men with the patriarch Abraham at Mamre in Palestine. Also included in icons of the Trinity are the appearance of the three divine Persons—symbolized as a hand, a man, and a dove—at the baptism of Jesus (Matthew 3:16 ff.) and the Pentecostal scene, in which the Lord, ascended to heaven, sits at the right hand of God and the Comforter (the Holy Spirit) is sent down to the Apostles in the form of fiery tongues (Acts 2). Another Trinitarian iconic scene is the Transfiguration of Jesus at Mount Tabor (Matthew 17:2).

Icons of Mary were probably first created because of the development of Marian doctrines in the 3rd and 4th centuries. The lack of New Testament descriptions of Mary was compensated by numerous legends of Mary that concerned themselves especially with wondrous appearances of miraculous icons of the mother of God. In Russian and many other Orthodox churches, including the monasteries at Mount Athos, such miraculous mother of God icons, "not made by hands," have been placed where the appearances of the mother of God took place.

The consecration liturgy of the icons of saints expresses the fact that the saints themselves, for their part, are viewed as likenesses of Christ. In them, the image of God has been renewed again through the working of salvation of the incarnate Son of God.

Varying views on the theology of icons

The foes of images explicitly deny that the New Testament, in relation to the Old Testament, contains any new attitude toward images. Their basic theological outlook is that the divine is beyond all earthly form in its transcendence and spirituality; representation in earthly substances and forms of the divine already indicate its profanation. The relationship to God, who is Spirit, can only be a purely spiritual one; the worship of the individual as well as the community can happen only "in spirit and in truth" (John 4:24). Similarly, the divine archetype can also be realized only spiritually and morally in life. The religious path of the action of God upon humans is not the path of external influence upon the senses but rather that of spiritual action upon the mind and the will. Such an effect does not come about through the art of painting. Opponents of icons thus claim that the only way to reach an understanding of the truth is by studying the writings of the Old and New Testaments, which are filled with the Spirit of God.

The decisive contrast between the iconodules (image

lovers) and the iconoclasts (image destroyers) is found in their understanding of Christology. The iconodules based their theology upon the view of Athanasius—who reflected Alexandrian Christology—that Christ, the God become human, is the visible, earthly, and corporeal icon of the heavenly Father, created by God himself. The iconoclasts, on the other hand, explain, in terms of ancient Antiochene Christology, that the image conflicts with the ecclesiastical dogma of the Person of the Redeemer. It is unseemly, according to their views, to desire to portray a personality such as Christ, who is himself divine, because that would mean pulling the divine down into the materialistic realm.

The theology of the iconoclasts of the Reformation period in the West made use, for the most part, of the same arguments. For the radical Protestants, the realization of God is only in the Word and sacrament.

After iconic theology had overcome opposition in the Byzantine imperial church, there were numerous Christian groups—especially in Asia Minor—in which the old hostility toward church icons was still maintained and which, in part, already had been forced into positions of heresy, such as the Paulicians (members of a 7th–9th-century dualistic sect).

The history of iconoclasm began in the early church with an emphatic (and, from the viewpoint of lovers of Greek and Roman culture, catastrophic) iconoclastic movement that led to the annihilation of nearly all of the sacred art of the pagan religions of the Roman Empire. In Western Christendom, an iconoclastic attitude was again expressed in various medieval lay movements and sects, such as the Cathari and the Waldenses. Iconoclasm underwent a revolutionary outbreak in the 16th-century Reformation in Germany, France, and England. Despite the different historical types of iconoclasm, a surprising uniformity in regard to their affective structure and theological argumentation exists. The Iconoclastic Controversy of the 7th and 8th centuries also became a point of contention in the Western Church. To be sure, the latter had recognized the seventh ecumenical council at Nicaea (787), in which iconoclasm was condemned. Nevertheless, an entirely different situation existed in the West. The Frankish–Germanic Church was a young church in which images were much more infrequent than in the old Byzantine Church, in which holy icons had accumulated over the centuries. In the West there was still no Christian pictorial art as highly developed as in the East. Also, Christianity there did not have to struggle against a highly developed pagan pictorial art. Donar, a Germanic god, reputedly whispered in a holy oak, and Boniface merely had to fell the Donar oak in order to demonstrate the superiority of Christ over the pagan god. Among the Germanic tribes in the West, there was no guild of sculptors or goldsmiths, as in Ephesus (Acts 19: 24 ff.), who would have been able to protest in the name of their gods against the Christian iconoclasts.

The difference between Eastern and Western views on icons

The Western viewpoint is revealed most clearly in the formulations of the synodal decisions on the question of images, as they were promulgated in the Frankish kingdom in the *Libri Carolini,* Charlemagne's code of laws. In this work it is emphasized that images have only a representative character. Thus, they are understood not as an appearance of the saint but only as a visualization of the holy Persons for the support of recollecting spiritual meanings that have been expounded intellectually through sermons. Hence, this led to an essentially instructional and aesthetic concept of images. The Western Church also viewed images as the Holy Scriptures' substitute for the illiterate—*i.e.,* for the overwhelming majority of church people in this period. Images thus became the Bible for the laity. Pope Adrian I, who encouraged Western recognition of the iconodulic Council of Nicaea, also referred to the perspicuity of the icons. This idea of perspicuity—*i.e.,* the appeal to one's imagination to picture the biblical persons and events to oneself—enabled him to recognize the Greek high esteem for the image without completely accepting the complicated theological foundation for icon veneration. The ideas articulated in the *Libri Carolini* remained decisive for the Western tradition. According to Thomas Aquinas, one of the greatest medieval theologians of the West, images in the church serve a threefold purpose: (1) for the instruction of the uneducated in place of books; (2) for illustrating and remembering the mystery of the incarnation; and (3) for awakening the passion of devotion, which is kindled more effectively on the basis of viewing than through hearing.

Western theology of icons

In the Western theology of icons, the omnipotence of the two-dimensionality of church art also was abandoned. Alongside church pictorial painting, ecclesiastical plastic arts developed; even painting in the three-dimensional form was introduced through the means of perspective. Art, furthermore, became embedded in the entire life of personal religiosity. The holy image became the devotional image; the worshiper placed himself before an image and became engrossed in his meditation of the mysteries of the Christian revelation. As devotional images, the images became the focal points for contemplation and mystical representation. Conversely, the mystical vision itself worked its way back again into pictorial art, in that what was beheld in the vision was reproduced in church art. The burden of ecclesiastical tradition, which weighs heavily upon Byzantine art, has been gradually abolished in the Western Church. In the Eastern Church the art form is just as fixed as ecclesiastical dogma; nothing may be changed in the heavenly prototypes. This idea plays little or no role in the West. There, religious art adjusts itself at any given time to the total religious disposition of the church, to the general religious mental posture, and also to religious needs. Religious art in the West also has been shaped by the imaginative fantasy of the individual artist. Thus, from the outset, a much more individual church art developed in the West. Thus, it became possible to dissociate sacred history from its dogmatic milieu and to transpose it from the past into the actual present, thereby allowing for an adaptable development of ecclesiastical art.

Missions. The missions and expansion of Christianity are among the most unusual of historical occurrences. Other world religions, such as Buddhism and Islām, also have raised a claim to universal validity, but no world religion other than Christianity has succeeded in realizing this claim through missionary expansion over the entire world (see also below *The Christian community and the world: Christian missions*).

The influence of the concept of the end time

The unique global expansion of Christianity is directly related to its expectation of the end time, in the imminent expectation of the return of Christ. The Christian expectation of the end time never consisted simply of a passive yearning for the coming Kingdom of God. Being grasped by faith in its immediately impending arrival was expressed instead in an intense activation and acceleration of efforts to prepare the world for the return of Christ and the coming of the Kingdom. This state of being grasped transformed itself into the pressing duty to "prepare the way of the Lord" (Matthew 3:3) and to remove all resistance to the establishment of the Kingdom on Earth.

This eschatological pressure stands behind both the earlier and the later achievements of an ever wider expansion of Christianity. Columbus, in undertaking to cross the ocean in a westerly direction in the 15th century, for example, believed that Satan had settled in India, thus successfully disrupting the extension of the gospel and delaying the return of Christ. According to his eschatological calculations, the time for the return of Christ was nearly at hand; thus, India had to be reached by the shortest way possible so that the last bulwark of Satan might be removed through Christian missions. The same eschatological expectation drove the Spanish Jesuit Francis Xavier to India and Japan in the 16th century. Protestant world missions, commencing a century later, also were influenced by the eschatological expectation of the end time (*e.g.,* the missions of the German Lutherans Bartholomäus Ziegenbalg and Heinrich Plütschau in India in the early 18th century and the missions of the Puritans among the Indians in Massachusetts in the late 17th century). The first seal of Massachusetts displayed an Indian with a beckoning hand and the inscription "Come over and help us"—the words of the Macedonian who appeared to the Apostle Paul in a night vision (Acts 16:9).

The leading missionaries of all times have accomplished great feats of extensive travels. On his numerous mission-

Extensive travels of Christian missionaries

ary journeys, the Apostle Paul showed a greater accomplishment in distances traveled than any known general of the Roman army, official of the Roman Empire, or trader of his time. Francis Xavier also traveled more than any other known person in his times and endured intense physical exertions on land and sea. John R. Mott, founder of the World's Student Christian Federation, was the most widely traveled man of the first half of the 20th century. The catchphrase coined by him, "Jesus Christ to the nations in this generation," has been the basic principle of all the great and small missionary impulses that have contributed to the worldwide expansion of Christianity.

This eschatological aspect of Christian missions has continued through the 20th century, especially among Pentecostals and Adventists. The missionary institutions of these churches come from the tradition of the conservative evangelical churches, which maintain a strong inclination toward an imminent expectation.

The ideal of ascetic homelessness

Related to the eschatological motif in missions is the ideal of ascetic homelessness. In imitation of the homeless Christ, who "has nowhere to lay his head" (Matthew 8:20), the early medieval Scots-Irish monks—as radical Christian ascetics—demanded the renunciation of that which is dearest to humans: one's own home. "For the sake of Christ" they assumed ascetic homelessness by leaving their cloisters—often in groups of 12 under the leadership of a 13th—and ventured abroad. They traveled to continental Europe—especially in Celtic areas—as far as Switzerland and over the Alps and also went to Iceland. Similarly, Russian Orthodox hermits and monks, who often had to flee because of repressive measures by the state and the state church, conducted missions in areas northeast of the Soviet Union, Siberia, the Aleutian Islands, and Alaska. An example of a modern ascetic missionary is the French nobleman Charles-Eugène de Foucauld (1858–1916), who became a martyred anchorite missionary among the Bedouin of the Sahara.

LAST THINGS

The "last things" were the first things, in terms of urgency, for the faithful of the early church. The central content of their faith and their hope was the coming Kingdom of God. They believed that the promises of the Old Testament about the coming bringer of salvation had been fulfilled in Jesus Christ, but that the fulfillment was not yet complete. Thus, they awaited Christ's Second Coming, which they believed was imminent.

Expectations of the Kingdom of God in early Christianity. In early Christianity's expectation of the Kingdom of God, two types were inherited from Judaism. The first was the expectation of a messianic Kingdom in this world, with its centre in Jerusalem, which was to be established by an earthly Messiah from the house of David. The second expectation was that of a heavenly Kingdom, which was to be inaugurated by the heavenly Messiah, Son of man, and in which the elected comrades of the Kingdom from all times would share in the state of the resurrection.

Types of expectations inherited from Judaism

The two types of expectation of salvation did not remain neatly separated in the early church but rather intersected one another in manifold ways. Under the influence of the persecutions of the church, a characteristic combination of the end-time expectations was established. In Paul's letters and in the Revelation to John, the faithful Christians will first reign together with their returning Lord for some time in this world. Those Christians who are still alive at his return will take part in the reign without dying (1 Thessalonians 4:17). Christians who have already died will rise again and, as resurrected ones, share in the Kingdom upon Earth. Only after completion of this first act of the events of the end time will there then follow the general resurrection of all the dead and the Last Judgment, in which the elect will participate as co-judges (1 Corinthians 6:2).

In the Revelation to John this expectation is condensed into the concept of the 1,000-year (millennial) Kingdom. For 1,000 years the dragon (Satan) is to be chained up and thrown into the abyss. In John's vision, Christians, the first resurrected, "came to life and reigned with Christ a thousand years" (Revelation 20:4). Only later does the resurrection of all the dead take place, as well as the general judgment, creation of the new heaven and the new Earth, and the descent of the new Jerusalem. According to the view of the Revelation to John, this 1,000-year Kingdom is composed of the chosen comrades of the Kingdom, especially the martyrs and all who stood the test in times of persecution; it is a Kingdom of the privileged elect.

Expectations of the millennium

This promise has exerted revolutionary effects in the course of church history. In the early church the expectation of the millennium was viewed as a social and political utopia, a state in which the chosen Christians would rule and judge with their Lord in this world. Such chiliastic (or millennial) expectations provided the impetus for ecclesiastical, political, and social reformations and revolutions in the course of church history. The establishment of a 1,000-year Kingdom in which the elect, with Christ, will reign and receive the administrative and judgeship posts has fascinated religious expectations as well as political and social imagination far more than the second part of the eschatological expectation, the "Last Judgment."

The delay of the Parousia resulted in a weakening of the imminent expectation in the early church. In this process of "de-eschatologizing," the institutional church increasingly replaced the expected Kingdom of God. The formation of the Roman Catholic Church as a hierarchical institution is directly connected with the declining of the imminent expectation. The theology of Augustine constitutes the conclusion of this development in the West. He de-emphasized the original imminent expectation by declaring that the Kingdom of God has already begun in this world with the institution of the church; the church is the historical representative of the Kingdom of God on Earth. The first resurrection, according to Augustine, occurs constantly within the church in the form of the sacrament of baptism, through which the faithful are introduced into the Kingdom of God. The expectation of the coming Kingdom of God, the resurrection of the faithful, and the Last Judgment have in actuality finally become a doctrine of the "last things" because the gifts of salvation of the coming Kingdom of God are interpreted as being already present in the sacraments of the church.

Expectations of the Kingdom of God in the medieval and Reformation periods. Nevertheless, the original imminent expectation has spontaneously and constantly reemerged in the history of Christianity. In the period before the 16th-century Reformation, heretical groups—such as the 2nd-century Montanists and the medieval Cathari, Waldenses, the followers of Joachim of Fiore, and the Franciscan Spirituals—accused the Roman Catholic Church of betraying the original eschatological imminent expectation. These groups revived eschatological expectations. Even within the Roman Catholic Church itself, however, such movements have constantly reemerged to inspire reform efforts. In the medieval church new outbreaks of an imminent expectation occurred in connection with great historical catastrophes, such as epidemics of the plague, Islāmic invasions, schisms, and wars.

Eschatological interpretations of the Reformers

Luther's Reformation also was sustained by an imminent expectation. For the Reformers, the starting point for their eschatological interpretation of contemporary history was that the "internal Antichrist," the pope, had established himself in the temple at the Holy Place and that through persecution by the "external Antichrist," the Turk, the church had entered into the travails of the end time. The Reformation churches, however, soon became institutional territorial churches, which in turn repressed the end-time expectation, and thus doctrine of the "last things" became an appendix to dogmatics.

Expectations of the Kingdom of God in the post-Reformation period. In the post-Reformation period, the imminent expectation appeared in individual groups on the margin of the institutional Reformation churches; such groups generally made the imminent expectation itself the object of their sect formation. This has been the result of the fact that, since the Reformation, the Roman Catholic Church has been virtually immune to eschatological movements. The Lutheran Church has been less immune; a series of eschatological groups whose activity in the church was determined by their expectation of the

imminent return of Christ appeared in Pietism. Among the congregational and evangelical churches of England and America, the formation of new eschatological groups has been a frequent occurrence, especially during the period of the English Revolution in the 17th century and during the revival movements in the United States in the 18th–20th centuries. Such groups shared significantly in the renewal and expansion of Christianity in domestic and foreign missions. Indeed, by late in the 20th century much of the Christian missionary outreach had passed into the hands of millennial-minded groups.

The role of imminent expectation in missions and emigrations. The great missionary activities of the Christian Church are in most cases based upon a reawakened imminent expectation, which creates a characteristic tension. The tension between the universal mission of the church and the hitherto omitted missionary duties as well as the idea that the colossal task must be accomplished in the shortest time possible renders comprehensible the astonishing physical and spiritual achievements of the great Christian missionaries. After the inundation of the old Christian areas of Africa and Asia by Islām, Franciscan missionaries in the 13th and 14th centuries, enduring incredible hardships, went by land and by sea to India, China, and Mongolia to preach the gospel. In a similar way, the missionary movement of the 18th and 19th centuries also proceeded from such eschatological groups within Protestantism.

The expectation of the Kingdom of God, in the form of the imminent expectation, plays a strong role in emigration movements. In a sense, the Crusades could be included among such movements. Great masses of European Christians again and again set out for Palestine with a sense of finding there the land of their salvation and personally being present when Christ returns there to establish his Kingdom. The eschatological strain of the Crusades can be noted in the Crusade sermons of Bernard of Clairvaux in 1147, who kindled enthusiasm to liberate Jerusalem with reference to the pressing terminal dates of the end time.

Eschatological ideas in emigrations

The emigration movement toward America also was influenced by beliefs in eschatologically fixed dates (*e.g.,* Columbus). Puritans who traveled to America in the 17th century and Quakers, Baptists, and Methodists in the 18th century believed that America was the "wilderness" promised in the Revelation to John. William Penn gave the name Philadelphia to the capital of the woodland areas ceded to him (1681) because he took up the idea of establishing the true church of the end time, represented by the Philadelphia community of the Revelation to John. A great number of the attempts undertaken to found radical Christian communities in North America may be viewed as anticipations of the coming Jerusalem. The same holds true for the emigration of German revivalists of the 18th and early 19th centuries to Russia and Palestine. The "Friends of the Temple"—Swabians who went with Christoph Hoffmann to Palestine in 1866—and the Swabians, Franks, Hessians, and Bavarians, who after the Napoleonic Wars followed the call of Tsar Alexander I to Bessarabia, were all dominated by the idea of living in the end time and preparing themselves for the coming Kingdom of God. In Tsar Alexander I they saw the "eagle . . . as it flew in midheaven" (Revelation 8:13), which prepared the "recovery spot" for them in the East upon which Christ will descend.

Eschatological expectations and secularization. In the eyes of some theologians, the very process of secularization, which progressively rules out transcendent explanations of natural and historical conditions, has been a working out of a form of eschatological expectation. Of course, the substance is quite different in the cases where people work in expectation of the Kingdom of God and in the other cases where they become "futurologists." But the impulse to prepare oneself for such futures has analogues and origins, it is contended, in old Christian ideas of penance and preparation for the coming Kingdom.

In the Gospels the attitude toward the coming Kingdom of God led, over and beyond the expectation of nullifying sin and death, to certain worldly conclusions of an organizational kind. The disciples of Jesus knew that there will be "first ones" in the Kingdom of Heaven; they pressed for the administrative posts in the coming Kingdom of God (*e.g.,* the Apostles James and John). The promise, too, that they are to take part as judges at the Last Judgment (Luke 22:30) sparked definite conceptions of rank. Jesus castigated them in their disputes over rank with the words, "If any one would be first, he must be last of all and servant of all" (Mark 9:35).

Despite this warning, the imminent expectation of the coming Kingdom of God awakened concrete, substantial ideas that led ever closer to social utopias. With the 18th-century German Lutheran mystic and Pietist F.C. Oetinger, the end-time expectation generated definite social and political demands—*e.g.,* dissolution of the state, abolition of property, and elimination of class differences. Some of the aspects of the end-time expectation of Pietism were revived in the French Revolution's political and social programs. The transition from the end-time expectation to the social utopia, however, had already been achieved in writings from the 16th and early 17th centuries—*e.g.,* the English humanist and saint Thomas More's . . . *de optimo reipublicae statu deque nova Insula Utopia* (1516; "On the Highest State of a Republic and on the New Island Utopia"), the German theologian Johann Valentin Andrea's *Reipublicae Christianopolitanae Descriptio* (1619; "A Description of the Christian Republic"), the English philosopher Francis Bacon's *New Atlantis* (1627), and the English bishop Francis Godwin's *Man in the Moone* (1638). It is also found in early socialism of the 19th century—*e.g.,* the French social reformer Henri de Saint-Simon's *Nouveau Christianisme* (1825; "The New Christianity") and the French Socialist Étienne Cabet's *Voyage en Icarie* (1840; "Voyage to Icaria").

Concepts of social utopias and futurology

What distinguishes the Christian social utopia from the earlier kind of eschatology is the stronger emphasis upon social responsibility for the preparation of the Kingdom of God and a considerable preponderance of various techniques in the establishment of the utopian society. (In general, the end-time expectation has also inspired technical fantasy and science fiction.) Also characteristic is the basic attitude that people themselves must prepare the future perfect society in a formative and organizing manner and that "hoping" and "awaiting" are replaced by human initiative. A graduated transition from a social utopia still consciously Christian to a purely Socialist one can be observed in the writings and activities of the French Socialists Charles Fourier, Saint-Simon, and Pierre-Joseph Proudhon, the English Socialist Robert Owen, and the German Socialist Wilhelm Weitling. Secularized remnants of a glowing Christian end-time expectation are still found even in the Marxist view of the social utopia.

Modern planning and projection of alternative futures is a secularization of the end-time expectations previously envisioned in Christian terms. The future is thus manipulated through planning (*i.e.,* "horizontal eschatology") in place of eschatological "hoping" and "waiting for" fulfillment. "Horizontal eschatology" is thus taken out of the sphere of the unexpected and numinous (spiritual); it is made the subject not only of a detailed prognosis based upon statistics but also of a detailed programming undertaken on the basis of this prognosis. An eschatological remainder is found only in an ideological image of man, upon which programming and planning are based.

Concepts of life after death. The Christian end-time expectation is directed not only at the future of the church but also at the future of the individual believer. It includes definite conceptions of the personal continuance of life after death. Many baptized early Christians were convinced they would not die at all but would still experience the advent of Christ in their lifetimes and would go directly into the Kingdom of God without death. Others were convinced they would go through the air to meet Christ returning upon the clouds of the sky: "Then we who are alive, who are left, shall be caught up together with them in the clouds to meet the Lord in the air; and so we shall always be with the Lord" (1 Thessalonians 4:17). In the early imminent expectation, the period between death and the coming of the Kingdom still constituted no ob-

ject of concern. An expectation that one enters into bliss or perdition immediately after death is also found in the words of Jesus on the cross: "Today you will be with me in Paradise" (Luke 23:43).

Eternal life and eternal death

In the Nicene Creed the life of the Christian is characterized as "eternal life." In the Gospels and in the apostolic letters, "eternal" is first of all a temporal designation: in contrast to life of this world, eternal life has a deathless duration. In its essence, however, it is life according to God's kind of eternity—*i.e.*, perfect, sharing in his glory and bliss (Romans 2:7, 10). "Eternal life" in the Christian sense is thus not identical with "immortality of the soul"; rather, it is only to be understood in connection with the expectation of the resurrection. "Continuance" is neutral vis-à-vis the opposition of salvation and disaster, but the raising from the dead leads to judgment, and its decision can also mean eternal punishment (Matthew 25:46). The antithesis to eternal life is not earthly life but eternal death.

Eternal life is personal life, and precisely therein is fulfilled the essence of man who is created according to the image of God. Within eternal life there are differences. In the present life there are variations in talent, duty, responsibility, and breadth and height of life, just as there are also distinctions in "wages" according to the measure of the occupation, the sacrifice of suffering, and the trial (1 Corinthians 3:8). Correspondingly, the resurrected are also distinguished in eternal life according to their "glory":

> There is one glory of the sun, and another glory of the moon, and another glory of the stars; for star differs from star in glory. So it is with the resurrection of the dead (1 Corinthians 15:41–42).

This expectation has had a great influence upon the Christian conception of marriage and friendship. The idea of a continuation of marriage and friendship after death has contributed very much to the deepening of the view of marriage, as is shown by the strong influence of the 17th–18th-century Swedish mystic, philosopher, and scientist Emanuel Swedenborg's ideas upon the romantic philosophy of religion and its interpretation of marriage and friendship in the thought of the German scholars Friedrich Schelling and Friedrich Schleiermacher. The Western concept of personality was thus deepened through the Christian view of its eternal value.

The delay of the imminent expectation brought about the question of the fate of the dead person in the period between the death of the individual Christian and the resurrection. Two basic views were developed. One view is that of an individual judgment, which takes place immediately after death and brings the individual to an interim state, from which he enters into the realm of bliss or that of perdition. The idea of an individual judgment, however, cannot be readily harmonized with the concept of the general Last Judgment on the day of the general resurrection of the dead. It anticipates the decision of the general judgment and thus deprives of its significance the notion of the Last Judgment. A second view, therefore, also prevailed: the sleep of the soul—*i.e.*, the soul of the dead person enters into a sleeping state that continues until the Last Judgment, which will occur after the general resurrection. At the Last Judgment the resurrected will be assigned either to eternal life or eternal damnation. This conception, accepted in many churches, contains many discrepancies, especially the abandonment of the fundamental idea of the continuity of personal life.

Both views contain an inhuman consequence. The first leaves to people no further opportunity to improve the mistakes of their lives and to expiate their guilt. The second preserves the personality in an intermediate state for an indefinite period so as to later punish it for sins or reward it for good deeds from a time prior to entrance into the sleep of the soul. The belief in purgatory (an interim state in which a correction of a dead person's evil condition is still possible) of the Roman Catholic Church gives the deceased opportunities for repentance and penance to ameliorate their situation.

The concept of purgatory

The presupposition of the doctrine of purgatory is that there is a special judgment for each individual at once after death. Hence, the logical conclusion is that purgatory ceases with the Last Judgment. The stay in purgatory can be shortened through intercession, alms, indulgences, and benefits of the sacrifice of the mass. The Eastern Orthodox Church has no doctrine of purgatory but does practice an intercession for the dead. It assumes that, on the basis of the connection between the church of the living and that of the dead, an exertion of influence upon the fate of the dead through intercession is possible before the time of the Last Judgment.

The idea of the Last Judgment has often become incomprehensible to the modern world. At the most, people apparently are still open to the concept of judgment of the guilt and innocence of the individual. The idea decisive for the early church's expectation of the Judgment, however, was that the Last Judgment will be a public one. This corresponds to the fundamental Christian idea that human beings—both the living and the dead—are bound together in an indissoluble communion; it presupposes the conception of the church as the body of Christ. All of humanity is as one person. Humans sin with one another, and their evil is connected together in the "realm of sin" in a manifold way, unrecognizable in the individual. Each person is responsible for the other and is guilty with the other. The judgment upon each person, therefore, concerns all. Judgment upon the individual is thus at the same time judgment upon the whole, and vice versa. The Judgment is also public in regard to the positive side—the praise and reward of God for that which is done rightly and practiced in the common life, often without knowing it.

For the most part, the churches of the latter part of the 20th century no longer have the courage to uphold the Christian teaching of life after death. The church has long neglected teachings about the entire area of the last things. The New Testament responses presuppose the imminent expectation and thus leave many questions unanswered that arose because of the delay of the Parousia. The doctrine of the sleep of the soul, on the other hand, contains many consequences that question the fundamental idea of the Christian view of the personality of the *imago Dei* ("image of God"). The beginnings of a further development of the Christian view of life after death, as are found in Swedenborg, have never been recognized positively by the church. For this reason, since the period of Romanticism and Idealism, ideas of the transmigration of souls and reincarnation, taken over from Hinduism and Buddhism, have gained a footing in Christian views of the end-time expectation. Some important impulses toward a new understanding of the view of life after death are found in Christian theosophy, such as the idea of a further development of the human personality upon other celestial bodies after death. (E.W.B./M.E.M.)

Effects of neglect of the doctrine of life after death

Church year

The Christian church year is an annual cycle of seasons and days observed in the Christian churches in commemoration of the life, death, and Resurrection of Jesus Christ and of his virtues as exhibited in the lives of his saints. This section surveys the origin and meaning, development, and current revisions of this cycle.

ORIGINS OF THE CHURCH YEAR

Religious times and seasons. The church year has deep roots in the primitive human impulse to mark certain times with sacral significance and ritual observance. These are times when conscious attention is given to the mysterious forces that surround and involve all living creatures in the natural and inexorable cycles of light and darkness; labour and rest; birth, growth, decay, and death.

Two interrelated cycles have had primary importance in the shaping of religious calendars. One is cosmic: the phases of the Moon and the solar equinoxes and solstices. The other is the periodic succession of the seasons of nature that determines times of sowing and reaping. Both cycles speak to the mystery of birth, death, and rebirth and to human dependence upon the fecundity of life given in the natural creation.

Jewish background. The Jewish religious year, grounded in the divinely revealed Law of the Old Testament, was the foundation for the church year of Christians. It is a lunar-

month calendar stemming from the primitive nomadic life of the Hebrews, with its chief festival at the first full moon of spring, known later as the Passover. Grafted onto this calendar after the settlement of the Hebrew tribes in Palestine were the agricultural festivals—dependent upon "the early and later rains"—the firstfruits at Passover, the first harvest at the Feast of Weeks or Pentecost, and the autumn harvest at the Feast of Tabernacles or Booths.

The sabbath

Of uncertain origin, but prior to the monarchical period (11th to 6th century BC), the Hebrews observed a seven-day week, of which the last day, or sabbath, was a holiday and day of rest. Whatever its original purpose, it became transformed into a sacral day, consecrated to Yahweh, the one God of the Hebrews, and increasingly surrounded with restrictions upon all activity other than worship. In the time of Jesus (1st century AD), "keeping holy the sabbath day" was a principal hallmark of adherence to Judaism.

The remarkable aspect of the Jewish religious year was its transformation, in successive codifications of the Old Testament Law, into a series of historical commemorations associated with God's deed in creation and in the redemption of God's people. At first, the sabbath was related to the Exodus, the deliverance of the Hebrews from Egypt in the 13th century BC (Deuteronomy 5:15), and, later, to the repose of God at the completion of creation (Exodus 20:8–11; Genesis 2:2–3). The three agricultural feasts became a sequence of remembrances of the Exodus from Egypt and the pilgrimage through the wilderness to the promised land (Exodus 12:1–20; Leviticus 23; Deuteronomy 16:1–17). Through these annual celebrations the devout Jew relived the saving events of the past and anticipated the final deliverance of the people of God in the age to come. Rabban Gamaliel, a contemporary of Jesus, said, "In every generation a man must so regard himself as if he came forth himself out of Egypt. . . ." (from Mishna, *Pesaḥim* 10:5).

Formation of the church year. In his earthly life Jesus was subject to the law of sabbath, feast, and fast prescribed in the Old Testament; but his ministry and teaching pointed to a new age, the coming Kingdom of God, when the Law would be fulfilled. He was, therefore, not so much concerned with outward conformity to legal regulations as he was with the spirit in which they were observed. "The sabbath was made for man, and not man for the sabbath" (Mark 2:27). It was in the context of a celebration of the Passover feast with his disciples that he was arrested, tried, and put to death.

Early Christians believed that the new age promised by Jesus had dawned with his Resurrection, on "the first day of the week" (Matthew 28:1; Mark 16:2; Luke 24:1; John 20:1). By this event the Law was fulfilled. Now every day and time were viewed as holy for the celebration and remembrance of Jesus' triumph over sin and death. Though many of his disciples continued to observe the special times and seasons of the Jewish Law, new converts broke with the custom because they regarded it as no longer needful or necessary. Paul, himself a dutiful observant of the Law, considered the keeping of holy days a matter of indifference, provided the devotion be "in honor of the Lord" (Romans 14:5–9). He warned his converts not to judge one another with regard "to a festival or a new moon or a sabbath" (Colossians 2:16).

From the beginning the church took over from Judaism the seven-day week. Before the end of the apostolic age (1st century AD), as the church became predominantly Gentile in membership, the first day of the week, or Sunday, had become the normative time when Christians assembled for their distinctive acts of worship, in commemoration of the Lord's Resurrection (Acts 20:7; 1 Corinthians 16:2). During the first two centuries AD, the Greco-Roman world in general adopted the planetary seven-day week of the astrologers.

Sunday

Christian writers of the 2nd century came to view Sunday, "the Lord's day," as a symbol of Christianity in distinction from Judaism. Most of the churches decided to observe the Lord's Passover (Easter) always on a Sunday, after the Jewish feast was over. In addition, local churches began to celebrate the anniversaries of the deaths of their martyrs, called "birthdays in eternity," for these also were regarded as witnesses to the resurrection triumph of Christ in his followers. The weekly Sunday and the annual Paschal (Passover) observance of 50 days from Easter to Pentecost (the Jewish harvest festival that also commemorated the revelation of the Law to Moses) were thus the principal framework of the church year until the 4th century—reminders of the new age to be brought by Christ at his coming again in glory at the end of time, when the true believers would enter their inheritance of perpetual joy and feasting with their Redeemer and Lord.

The establishment of Christianity as a state religion, following the conversion of the emperor Constantine (AD 312), brought new developments. The Paschal season was matched by a longer season of preparation (Lent) for the many new candidates for baptism at the Easter ceremonies, and the discipline and penance of those who for grievous sins had been cut off from the communion of the church.

A new focus of celebration, to commemorate the birthday of Christ, the world Redeemer, was instituted at ancient winter solstices (December 25 and January 6) to rival the pagan feasts in honour of the birth of a new age brought by the Unconquered Sun. Later, the Western churches created a preparatory season for this festival, known as Advent. Many new days were gradually added to the roster of martyr anniversaries to commemorate distinguished leaders, the dedication of buildings and shrines in honour of the saints, and the transferral of their relics.

THE MAJOR CHURCH CALENDARS

Unlike the cycle of feasts and fasts of the Jewish Law, the Christian year has never been based upon a divine revelation. It is rather a tradition that is always subject to change by ecclesiastical law. Each self-governing church maintains the right to order the church year according to pastoral needs of edification. The pattern of the year therefore varies in the several churches of the East and of the West. The subtle adjustments of a lunar-month calendar, with its movable date of Easter, and a solar calendar of fixed dates require many rules to avoid conflict of observances.

Reforms in the church year

In the Western churches periodic reforms of the church year have occurred, notably in the Reformation era and again in the 20th century. The Protestant Reformers of the 16th century took differing attitudes toward such reforms. With their strong sense of the prime authority of Scripture and of the freedom of the gospel from all legalisms in liturgical matters, they revised the church year with varying degrees of radicalism. Lutherans and Anglicans took a conservative position, retaining the traditional seasons but eliminating commemorations that had no connection with the biblical record.

The Reformed churches, on the other hand, allowed only those feasts with a clear basis in the New Testament: Sundays, Holy Week and Easter, Pentecost, and in some cases Christmas. The Church of Scotland and Anabaptist and Puritan groups abolished the church year entirely, except for Sundays. In recent years this attitude has been very much modified. Their protest has been a reminder to the church that all days are regarded as belonging to Christ in the freedom of his Spirit, who cannot be controlled by rigid systems of fixed special observances.

In the late 20th century in the Western churches the church year was being subjected to an overall revision comparable in scope only to that of the 16th century. This was due to a number of currents of interest that were converging; *i.e.*, advances in historical and liturgical studies, changes in theological perspectives, and ecumenical encounters.

The basic structure of the church year was the creation of the ancient churches in the varied cultures surrounding the Mediterranean Sea that were embraced in the Roman Empire. Christian missionaries have carried the church year throughout the world—first in the Northern Hemisphere and, since the 16th century, in the Southern Hemisphere, where the natural seasons are reversed. It is unlikely that the dates of the two major feasts, Easter and Christmas, which control the seasons of the church year, will be changed. But new symbols and popular customs

associated with them will emerge in areas where, for example, Easter is celebrated in the autumn rather than as a spring festival.

The church year consists of two concurrent cycles: (1) the Proper of Time (Temporale), or seasons and Sundays that revolve around the movable date of Easter and the fixed date of Christmas, and (2) the Proper of Saints (Sanctorale), other commemorations on fixed dates of the year. Every season and holy day is a celebration, albeit with different emphases, of the total revelation and redemption of Christ, which are "made present at all times" or proclaim "the paschal mystery as achieved in the saints who have suffered and been glorified with Christ" (second Vatican Council, "Constitution on the Sacred Liturgy"). The church year is an epitome in time of the history of salvation in Christ.

Orthodox calendar

Eastern churches. The Orthodox churches of the Byzantine tradition recall the Resurrection of Christ every Sunday. Many Sundays take their title from the Gospel lesson for the day. In addition to Easter, "the feast of feasts," there are 12 other major feasts: Christmas, Epiphany, Hypapante (Meeting of Christ with Simeon, February 2), Palm Sunday, Ascension, Pentecost, Transfiguration (August 6), Exaltation of the Holy Cross (September 14), and four feasts of the Blessed Virgin Mary—her Nativity (September 8), Presentation in the Temple (November 21), Annunciation (March 25), and Falling Asleep (August 15).

The principal cycle consists of (1) 10 weeks before Easter, contained in the *Triōdion* (pre-Easter liturgical service book); the first four of these Sundays prepare for the Great Fast, or Lent (*i.e.*, the Sunday of the Pharisee and Publican; the Sunday of the Prodigal Son; Meat-Fast Sunday, after which abstinence from meat is enjoined; and Cheese-Fast Sunday, after which the fast includes cheese, eggs, butter, and milk), and (2) eight weeks after Easter, contained in the *Pentēkostarion* (post-Easter liturgical service book), including the Feast of Ascension, 40 days after Easter, and concluding with the Festival of All Saints on the Sunday after Pentecost. Other special commemorations of the period are the Feast of Orthodoxy, on the first Sunday in Lent, recalling the end of the Iconoclastic Controversy in 843, and the feast of the Fathers of the first Ecumenical Council of Nicaea in 325 on the sixth Sunday after Easter.

The schedule of fixed holy days in the Menaion (liturgical service book for each month) begins on September 1, the New Year's or Indiction Day of the Byzantine Empire. It includes the invariable feasts of Christ, St. Mary and other Christian saints, and many Old Testament saints.

Calendar of the Eastern independent churches

The separated churches of the East (those not accepting the jurisdiction of Orthodox patriarchs or bishops) have calendars basically similar to the Byzantine. West Syrians (Jacobites) and East Syrians (Nestorians) begin the year with a series of Sundays devoted to themes of the Dedication of the Church (consecration by a bishop) and the Annunciation (of the angel Gabriel to Mary that she would bear the Son of God)—the West Syrian sequence starting on November 1, the East Syrian on December 1. There are few saints' days in the Nestorian calendar. The Copts (Egyptians) and Ethiopians date their year from August 29, considered the beginning of the Christian Era in the persecution of the emperor Diocletian (AD 303–311). They have some 32 feasts of the Virgin Mary and many feasts of angels. The Armenian Church follows the Byzantine in beginning the year with the preparatory Sundays before Lent, but it commonly observes fixed holy days on the nearest Sunday. It is the only ancient church that never adopted the feast of Christmas on December 25 but celebrates the incarnation only on Epiphany, January 6.

Roman Catholic Church. The church year begins on the first Sunday in Advent, which is the fourth Sunday before Christmas Day. Until 1969, after Advent and Christmas, there followed the seasons of Epiphany, Pre-Lent, Lent, Easter, Ascension, and Pentecost. The first day of Lent is Ash Wednesday, being the 40th day (exclusive of Sundays) before Easter. A special festival of the Holy Trinity occurs on the first Sunday after Pentecost. Corpus Christi, a feast celebrating the Real Presence of Christ in the bread and wine of the Eucharist (Communion meal, or the Lord's Supper), was instituted in 1264 by Pope Urban IV and is observed on the Thursday after Trinity Sunday. In 1925 Pope Pius XI created the Feast of Christ the King, assigned to the last Sunday in October.

Fixed holy days

Until 1969, the fixed holy days began with St. Andrew (November 30), the nearest to the beginning of Advent. The three days before Ascension Day, called Minor Rogation Days ("Days of Asking"), are devoted to special prayers for fruitful harvests. Found only in the Roman Catholic Church are the fasts of the four seasons (*quatuor tempora*), known as Ember Days, and especially associated with ordinations to the ministry. They occur on the Wednesdays, Fridays, and Saturdays after the third Sunday of Advent and the first Sunday in Lent, in the week of Pentecost and the week after Holy Cross Day (September 14).

A revised calendar was issued by Pope John XXIII in 1960. The "Constitution on the Sacred Liturgy" of the second Vatican Council called for further reforms. These have been completed in the new calendar and lectionary promulgated by Pope Paul VI in 1969.

The most important feature of the new calendar was the restoration of all Sundays as feasts of Christ. No saints' days, even of the Virgin Mary, may take precedence of a Sunday. In the Proper of Time, the season of Pre-Lent was eliminated, and two cycles were provided: (1) the principal seasons, Sundays, and holy days from Advent to Pentecost and (2) a schedule of 33 Sundays per annum to be observed in numbered sequence in place of the Sundays previously designated "after Epiphany" and "after Pentecost." The ancient Roman Feast of St. Mary was restored to January 1; a new Feast of the Baptism of Christ was assigned to the first Sunday after Epiphany; and the Feast of Christ the King was shifted to the last Sunday of Ordinary Time. All octaves were eliminated. Fixed holy days are now arranged from January 1.

The revised Roman Catholic calendar

A considerable simplification, reclassification, and in many cases shifting of dates were made in the Proper of Saints. Except for 13 "solemnities" (including major feasts of Christ and Mary) and 25 "feasts," all other saints' days and holy days were reduced to "memorials," either obligatory or optional—with the right of national and regional episcopal conferences to alter their rank. Ember and Rogation Days were assigned as votive masses to be observed according to regional directives.

Regulations regarding holy days and processes leading to the canonization of saints are controlled by the Sacred Congregation for Divine Worship (formerly the Congregation of Rites). Certain feasts, in addition to all Sundays, are designated "holy days of obligation," when all the faithful must attend Mass. In the United States these are: Christmas Day (December 25), the Feast of St. Mary (New Year's Day), Ascension Day, the Assumption of the Blessed Virgin Mary (August 15), All Saints' Day (November 1), and the Immaculate Conception of the Blessed Virgin Mary (December 8). In addition to these, "days of obligation" observed elsewhere include: St. Joseph's Day (March 19), the Annunciation (March 25), SS. Peter and Paul Day (June 29), and the Feast of Corpus Christi.

Protestant churches. Lutheran and Anglican churches preserve in their liturgies the seasons of the Roman Catholic calendar; but in general they reduced the fixed holy days to primary feasts of Christ and the Apostles and evangelists, Michaelmas Day (September 29), and All Saints' Day (November 1). In the second half of the year, Sundays were named "after Trinity." In the late 20th century the revisions of Lutheran and Anglican service books were influenced by the new designs of the Roman Catholic calendar, notably proposals to eliminate Pre-Lent and to name Sundays "after Pentecost" instead of "after Trinity." Anglican and Lutheran calendars were also enriching their entries with many non-biblical saints and holy days, but for optional observance. Lutherans celebrate a festival of the Reformation on October 31 or the Sunday preceding that date.

In other Protestant churches, only Sunday observance remains obligatory, including Easter and Pentecost. Holy Week is frequently observed, and Christmas is commonly celebrated liturgically on the Sunday preceding Decem-

ber 25. Among these Protestant churches, new service books and hymnals have exhibited interest in recovering the major seasons of the Proper of Time, from Advent to Pentecost, and in some cases the Feast of All Saints. Especially significant was the restoration of the seasons in the Reformed (Presbyterian) and Methodist churches.

Many Protestant churches devote Sundays to special themes of a religious, charitable, or civic nature, such as Race Relations, Rural Life, Christian Home, and Labour Sundays. Harvest festivals, common in the Western churches since the Middle Ages, have a distinctive American tradition in Thanksgiving Day, on the fourth Thursday in November. Traditionally held to have originated in the Plymouth (Mass.) colony in 1621, it was first proclaimed a national holiday by President Abraham Lincoln in 1863. Ecumenical services, now worldwide, are observed during the Octave or Week of Prayer for Christian Unity, January 18–25—a custom started by Paul James Wattson of the Franciscan Friars of the Atonement and developed by Abbé Paul Couturier. The week is jointly sponsored by the World Council of Churches and the Vatican Secretariat for Promoting Christian Unity.

HISTORY OF THE CHURCH YEAR

Sunday. Regular Christian corporate worship on Sundays goes back to the apostolic age, but New Testament writings do not explain how the practice began. Jewish Christians probably kept the sabbath at the synagogue, then joined their Gentile fellow believers for Christian worship after the close of the sabbath at sundown, either in the evening or early Sunday morning. When the church became predominantly Gentile, Sunday remained as the customary day of worship. Assemblies for the Eucharist were common on Saturday, however, as well as on Sunday in the Eastern churches into the 5th century, and Eastern canons forbade the practice, customary in the Roman Church, of fasting on the sabbath.

The term Lord's Day, signifying the triumph of Christ in his Resurrection and the beginning of a new creation, was in use by the end of the 1st century (Revelation 1:10; *Didachē* 14; Ignatius of Antioch, *Magnesians* 9:1). Some writers referred to the sabbath as the rest promised to the people of God at the end of time and to Sunday as "the eighth day," or beginning of a new world (Hebrews 4:4–11; *Letter of Barnabas* 15).

Sunday as a legal holiday

In 321 the Roman emperor Constantine decreed Sunday to be a legal holiday and forbade all trade and work other than necessary agricultural labour. Later emperors extended the prohibition to include public amusements in the theatre and circus. Church councils of the period were more concerned to enforce the obligation of Sunday worship, the earliest being the Spanish Council of Elvira (*c.* 300); but a synod of Laodicea (*c.* 381) enjoined Christians not to "Judaize" but to work on the sabbath and rest, if possible, on the Lord's Day. The Old Testament commandment of sabbath rest received a spiritual interpretation from the Church Fathers when they applied it to Sunday; *e.g.,* Augustine of Hippo held that the sabbath rest from servile work meant abstention from sin (compare *Tract. in Joannis,* Book III, chapter 19; Book XX, chapter 2).

A literal application of the sabbath law to Sunday became evident in conciliar canons and civil laws of the Frankish kingdoms in the 6th century, climaxed by Charlemagne's capitulary adopted by the Council of Aachen, 789 (canon 80). Medieval legislation thereafter repeatedly sought to enforce the "holiday" of Sunday, as also of many other holy days, for the benefit of serfs and labourers.

Sabbatarian laws applied to Sunday were also continued by the Protestant Reformers. The Acts of Uniformity of Edward VI in 1552 and of Elizabeth I in 1559 required all persons to attend worship on Sunday, the latter imposing a fine for neglect to do so. The Church of England's Canons of 1604 (number 13) make similar provision. Many Puritans were strongly sabbatarian in sentiment. Some of them referred to Sunday as "the sabbath." In the Puritan colonies of New England, the so-called Blue Laws of Sunday observance were especially severe. Today some states and cities in the United States have statutes restricting certain trades and amusements on Sunday. Church laws continue to insist upon the moral obligation to attend worship every Lord's Day.

Blue Laws

Advent. The Advent (from Latin *adventus,* "coming") season is peculiar to the Western churches, though its original impulse probably came from the East, where it was common, after the ecumenical Council of Ephesus in 431, to devote sermons on Sundays before Christmas to the theme of the Annunciation. In Ravenna—a channel of Eastern influences upon the Western Church—Peter Chrysologus (reigned *c.* 433–450) delivered such homilies (sermons). The earliest reference to a season of Advent is the institution by Bishop Perpetuus of Tours (reigned 461–490) of a fast before Christmas, beginning from St. Martin's Day on November 11. Known as St. Martin's Lent, the custom was extended to other Frankish churches by the Council of Mâcon in 581.

The six-week season was adopted by the church of Milan and the churches of Spain. At Rome, there is no indication of Advent before the latter half of the 6th century, when it was reduced—probably by Pope Gregory I the Great—to four weeks before Christmas. The longer Gallican season left traces in medieval service books, notably the Use of Sarum (Salisbury), extensively followed in England, with its Sunday before Advent. The coming of Christ in his Nativity was overlaid with a second theme, also stemming from Gallican churches, namely, his Second Coming at the end of time. This interweaving of the themes of two advents of Christ gives the season a peculiar tension both of penitence and of joy in expectation of the Lord who is "at hand."

Popular piety in Advent is chiefly devoted to musical and dramatic performances based upon biblical prophecies and stories of the Nativity of Christ. In many homes and churches simple devotions are associated with an Advent evergreen wreath, in which four candles are inserted and lighted, one by one, each week, as a symbol of the coming of the "Light" of the world.

Christmas. The word Christmas is derived from the Old English *Cristes maesse,* "Christ's Mass." There is no certain tradition of the date of Christ's birth. Christian chronographers of the 3rd century believed that the creation of the world took place at the spring equinox, then reckoned as March 25; hence the new creation in the incarnation (*i.e.,* the conception) and death of Christ must therefore have occurred on the same day, with his birth following nine months later at the winter solstice, December 25. The oldest extant notice of a feast of Christ's Nativity occurs in a Roman almanac (the Chronographer of 354, or Philocalian Calendar), which indicates that the festival was observed by the church in Rome by the year 336.

Many have posited the theory that the feast of Christ's Nativity, the birthday of "the sun of righteousness" (Malachi 4:2), was instituted in Rome, or possibly North Africa, as a Christian rival to the pagan festival of the Unconquered Sun at the winter solstice. This syncretistic cult that leaned toward monotheism had been given official recognition by the emperor Aurelian in 274. It was popular in the armies of the Illyrian (Balkan) emperors of the late 3rd century, including Constantine's father. Constantine himself was an adherent before his conversion to Christianity in 312. There is, however, no evidence of any intervention by him to promote the Christian festival. The exact circumstances of the beginning of Christmas Day remain obscure.

From Rome the feast spread to other churches of the West and East, the last to adopt it being the Church of Jerusalem in the time of Bishop Juvenal (reigned 424–458). Coordinated with Epiphany, a feast of Eastern origin commemorating the manifestation of Christ to the world, the celebration of the incarnation of Christ as Redeemer and Light of the world was favoured by the intense concern of the church of the 4th and 5th centuries in formulating creeds and dogmatic definitions relating to Christ's divine and human natures.

Christmas is the most popular of all festivals among Christians and many non-Christians alike, and its observance combines many strands of tradition. From the ancient Roman pagan festivals of Saturnalia (December 17) and New Year's come the merrymaking and exchange

of presents. Old Germanic midwinter customs have contributed the lighting of the Yule log and decorations with evergreens. The Christmas tree comes from medieval German mystery plays centred in representations of the Tree of Paradise (Genesis 2:9). Francis of Assisi popularized the Christmas crib, or crèche, in his celebration at Greccio, Italy, in 1223.

Another popular medieval feast was that of St. Nicholas of Myra (*c.* 340) on December 6, when the saint was believed to visit children with admonitions and gifts, in preparation for the gift of the Christ child at Christmas. Through the Dutch the tradition of St. Nicholas (Sinterklaas, hence "Santa Claus") was brought to America in their colony of New Amsterdam, now New York. The sending of greeting cards at Christmas began in Britain in the 1840s and was introduced to the United States in the 1870s.

Epiphany. In Hellenistic times an epiphany (from the Greek *epiphania,* "manifestation"), or appearance of divine power in a person or event, was a common religious concept. The New Testament uses the word to denote the final appearing of Christ at the end of time; but in 2 Timothy 1:10 it refers to his coming as Saviour on earth. In this latter sense, a festival of Christ's epiphany is first attested among heretical Gnostic Christians (those who believed that mankind was saved by secret knowledge, not faith, and that matter was evil and the spiritual world good) in Egypt in the late 2nd century (Clement of Alexandria, *Strōmateis,* Book I, chapter 21), on January 6, when he was manifested as Son of God at his baptism. The date is that of an Egyptian solstice, celebrated by pagans as a time of overflow of the waters of the Nile, and in certain mystery cults as the occasion of the birth of a new eon, or age, from the virgin goddess Kore, daughter of the earth-mother goddess Demeter. In other places of the Middle East, the time was associated with miraculous fountains from which wine flowed in place of water.

Nothing more is known of an Epiphany feast until the 4th century, when it appears in the Eastern churches as a festival second in rank only to Easter. It commemorated three "manifestations": the birth, the baptism, and the first miracle of the Lord at Cana (John 2:1 ff.). In the latter half of the century Eastern and Western churches adopted each other's incarnation festival, thus establishing the 12-day celebration from Christmas to Epiphany. The particular emphasis in the Eastern feast upon the baptism of Christ led to special liturgical ceremonies of the blessing of waters and the ministration of baptism at this time. In the West, where Christmas was the primary festival, the Epiphany was associated particularly with the Adoration of the Magi to the infant Jesus (Matthew 2:1–12), as anticipation of the universal redemption of Christ in his "Manifestation to the Gentiles."

The 12 days of Christmas

Pre-Lent. A season of Pre-Lent, peculiar to the Roman Catholic rite, was eliminated from that calendar in 1969. It had developed in the 6th century as a time of special supplication for God's protection and defense in a period of great suffering in Italy from war, pestilence, and famine. It was marked by three Sundays before the beginning of Lent, called, respectively, Septuagesima, Sexagesima, and Quinquagesima—roughly 70, 60, and 50 days before Easter. Though not included in the discipline of Lenten penitence and fast, the season was related by some authorities to influences from the East, especially upon Roman monastic customs, for a longer Lent of eight weeks.

Shrove Tuesday, the day before Ash Wednesday (the initial day of Lent), is in many places a day of carnival, though its name derives from the custom of going to confession for absolution and penance before Lent (from the Middle English word *shriven,* "to shrive"). A famous carnival is that of Mardi Gras (French: "Fat Tuesday") in New Orleans.

Lent. The Lenten (from Middle English *lenten,* "spring") season is rooted in the preparation of candidates for baptism at the Paschal vigil. For several weeks they received intensive instruction, each session followed by prayer and exorcism. The earliest detailed account of these ceremonies is in the *Apostolic Tradition* (*c.* 200) of Hippolytus. At the conclusion all the faithful joined the catechumens (inquirers for instruction) in a strict fast on the Friday and Saturday before Easter. These were the days "when the Bridegroom was taken away" (compare Mark 2:20).

As a 40-day period (six weeks) Lent is mentioned in canon 5 of the first ecumenical Council of Nicaea in 325. In the 4th century instruction of the baptismal candidates was normally given by the bishop. Several such "catechetical lectures" on the creed and sacraments have survived, notably those of Cyril of Jerusalem and Theodore of Mopsuestia. Augustine's treatise *De catechizandis rudibus* (*c.* 400) gave a less dogmatic and more biblical and historical approach. The Roman Church organized its instruction around three (later seven) "scrutinies," at which the catechumens were introduced to the Gospels, the Apostles' Creed, and the Lord's Prayer.

Since Sunday was never a fast day, piety sought to conform the Lenten fast exactly to 40 days, after the examples of the 40 days in the wilderness of Moses, Elijah, and Christ. In the Eastern churches, where Saturdays were also excluded from fasting, this developed into an eight-week Lent. At Rome, from the late 5th century, the fast began on Wednesday before the first Sunday in Lent.

Ash Wednesday and Holy Week

During Lent also, grievous sinners were excluded from Communion and prepared for their restoration. As a sign of their penitence, they wore sackcloth and were sprinkled with ashes (Tertullian, *De paenitentia* 11; compare the biblical precedents: Jeremiah 6:26; Jonah 3:6; Matthew 11:21). This form of public penance began to die out in the 9th century. At the same time, it became customary for all the faithful to be reminded of the need for penitence by receiving an imposition of ashes on their foreheads on the first day of Lent—hence the name Ash Wednesday.

The last week of Lent was one of special devotion in remembrance of the Lord's Passion. Athanasius in his *Festal Letter* of 330 called it "holy Paschal week." The Church of Jerusalem in particular organized dramatic ceremonies during the week at appropriate holy sites of its neighbourhood. A detailed description is contained in the account of a Spanish nun (*c.* 395), *Peregrinatio ad loca sancta* (or *Peregrinatio Etheriae*). From Jerusalem many of these ceremonies, such as the Palm Sunday procession and the Good Friday veneration of the cross, spread to other churches.

The Roman Catholic liturgy of Holy Week begins with the blessing of palms and a procession on Sunday, with a solemn rendition of St. Matthew's Passion narrative at the mass. On Thursday the bishop blesses the sacred oils for the catechumens and the sick and the chrism (oil) for confirmation, and, in ancient times, penitents were reconciled for their Easter Communion. After a festal mass commemorating the institution of the Eucharist, the altars are stripped and washed. An additional ceremony, of medieval origin, has given its name to this day—the washing of feet, in imitation of the Lord's action at the Last Supper (John 13:2–15). It is popularly called the Maundy, from the anthem sung during the ceremony (Mandatum, "a new commandment," John 13:34).

Maundy Thursday

Another medieval custom, which has had a popular revival in the late 20th century, is the service of Tenebrae, held on Wednesday, Thursday, and Friday, in the evening. It is the old choir office of Matins and Lauds, originally sung before dawn and marked by the gradual extinguishing of candles before the breaking of the light of day.

On Good Friday (the day commemorating the Crucifixion of Christ), the Mass of the Presanctified is observed. Its name is derived from the fact that there is no consecration of the sacred elements of bread and wine; instead, Communion is ministered from the Reserved Sacrament (consecrated elements retained from previous celebrations). Other features are the singing of the Passion according to John, the impressive series of intercessions, and the adoration of the cross with singing of the Reproaches and the hymn "Pange lingua" ("Sing, my tongue, the glorious battle"). Following the Communion and dismissal of the people, there are no further liturgical rites other than the daily choir offices until the vigil of Easter.

Easter. The term Easter, commemorating the Resurrection of Christ, comes from the Old English *ēaster* or *ēastre,*

a festival of spring; the Greek and Latin Pascha, from the Hebrew Pesaḥ, "Passover." The earliest Christians celebrated the Lord's Passover at the same time as the Jews, during the night of the first (paschal) full moon of the first month of spring (Nisan 14–15). By the middle of the 2nd century most churches had transferred this celebration to the Sunday after the Jewish feast. But certain churches of Asia Minor clung to the older custom, for which they were denounced as "Judaizing" (Eusebius, *Ecclesiastical History,* Book V, chapters 23–25). The first ecumenical Council of Nicaea in 325 decreed that all churches should observe the feast together on a Sunday. Yet many disparities remained in the way the several churches calculated the date of Easter. Today the Eastern churches follow the Julian calendar, the Western churches its correction by Pope Gregory XIII in 1582, so that in some years there may be a month's difference in the time of celebration.

Differences in the celebration of Easter

Since 1900, various religious, business, and professional groups have promoted the concept of a fixed world calendar, which would include a fixed date for Easter. Proposals have been placed before the League of Nations and its successor, the United Nations. The second Vatican Council in its "Constitution on the Sacred Liturgy" (1963) accepted the principle of a fixed date for Easter, subject to approval by other churches, provided that no world calendar impaired the regular succession of a seven-day week. The World Council of Churches in the early 1970s canvased its member bodies to this end, and a large majority replied in favour of such a change. An Easter message of Athenagoras I, the Orthodox Patriarch of Constantinople, in 1969, called for a resolution of the differences between the Eastern and Western churches and a search for a common date. Among those preferring a fixed date for the observance of Easter—regardless of the issue respecting a common world calendar—the second Sunday in April has been widely proposed.

The Easter celebration continues for 50 days, to and including the Feast of Pentecost. In the early church, as on all Sundays, there was no fasting or kneeling in prayer during the period.

The liturgy began with a solemn vigil on Saturday evening. A new fire was lit for the blessing of the Paschal candle (the Exultet)—symbol of the driving away of the powers of darkness and death by the Passover of the Lord. There followed a series of lessons from the Old Testament, with a homily based upon the narrative of Exodus 12. Then, toward midnight, while the faithful were engaged in prayers, candidates for baptism were taken to the baptistery for their initiation. Returning to the assembly, they were confirmed by the bishop with chrism and the laying on of hands, and toward dawn the Easter Eucharist was completed. A similar celebration was repeated on the eve of Pentecost for those who were hindered from receiving baptism at Easter.

As at Christmas, so also at Easter, popular customs reflect many ancient pagan survivals—in this instance, connected with spring fertility rites, such as the symbols of the Easter egg and the Easter hare or rabbit. The Easter lamb, however, comes from the Jewish Passover ritual, as applied to Christ, "the Lamb of God" (compare John 1:29, 36; 1 Corinthians 5:7).

Ascension. At first, the church commemorated the Ascension (from the Latin *ascensio,* "ascent") of Christ into heaven, after his Resurrection (Luke 24:50–51; Acts 1:1–11), as part of the total victory of Christ celebrated from Easter to Pentecost. A special feast of the Ascension is not mentioned before the 4th century. The Spanish Council of Elvira (*c.* 300) appears to have rejected it as an unwarranted innovation. But by the end of the 4th century the feast had become universal in the church, on the 40th day after Easter.

The old English popular name for the feast is Holy Thursday, but there is no liturgical tradition to support the idea of an "Ascensiontide" as a season distinct from Easter. From the 10th century there developed an "octave" of Ascension, adopted at Rome in the 12th century but suppressed in 1955. The three days before Ascension Day, known as Minor Rogation Days, were instituted by Bishop Mamertus of Vienne (Gaul) in 470 and extended to all the Frankish churches at the Council of Orléans in 511. Pope Leo III (reigned 795–816) adopted them at Rome. They are observed by processional litanies and fasting as a supplication for clement weather for the crops and deliverance from pestilence and famine. In 1969 the Minor Rogation Days were changed to votive masses.

Pentecost. The Jews had an early harvest festival seven weeks after the firstfruit offerings of Passover, called the Feast of Weeks. The Priestly Code (Leviticus 23:15–16) assigned it to "the morrow after the seventh sabbath"—which would be a Sunday. Early rabbinic tradition (Babylonian Talmud, *Pesaḥim* 68b) associated the festival with the giving of the Law at Sinai, on the basis of Exodus 19:1.

The Christian festival of Pentecost (from the Greek *pentecoste,* "50th day"), unlike Easter, is not rooted in Judaism but is based upon the narrative of Acts 2, recording the gift of the Holy Spirit to the disciples and the launching of the church's mission to all peoples on the Pentecost that followed the Lord's Resurrection. The outpouring of the Spirit was the final seal upon Christ's redemptive work, a sign of the inauguration of the new age when the Law was fulfilled and the way to salvation opened to the Gentile peoples. For this reason the early Christians considered Pentecost to be included in, but climactic of, the great "50 days" of Easter. Pentecost was in fact the name commonly given by the early Fathers to the whole season.

New Testament origins of Pentecost

As early as the 5th century, baptisms were administered at Pentecost to those unable to be initiated at Easter, and a vigil rite was developed comparable to that of the Pascha (Leo the Great, *Letters* 16; Leonine and Gelasian sacramentaries). The Anglo-Saxons called the feast White Sunday (Whitsunday), from the white garments bestowed upon the newly baptized (compare Bede, *Ecclesiastical History,* Book II, chapter 9; *Penitential* of Archbishop Theodore of Tarsus). The term Whitsunday has been customary in the Anglican churches since the First Prayer Book of Edward VI (1549).

Pentecost or Trinity Season. The Sundays after Pentecost mark the season of the life of the church between the two advents of Christ as it fulfills its mission to the world under the guidance of the Spirit. Bishop Stephen of Liège (reigned 902–920) instituted a Feast of the Holy Trinity on the first Sunday after Pentecost, which spread through northern Europe. It was taken up in the Use of Sarum and was accepted at Rome in 1334 by Pope John XXII. It became common to date the Sundays after this feast, instead of after Pentecost, as in the Roman liturgy, and this practice was followed by the Carthusians and the Dominicans and in the Lutheran and Anglican churches.

Saints' days and other holy days. The celebration of days in honour of the saints or "heroes of the faith" is an extension of the devotion paid to Christ, since they are commemorated for the virtues in life and death that derive from his grace and holiness. Originally each local church had its own calendar. Standardization came with the fixation of the rites of the great patriarchal sees, which began in the 4th century and was completed for the Byzantine churches in the 9th century. The Roman calendar of the Gregorian Sacramentary became the basis of the Western Church's observances with the liturgical reform of Charlemagne (*c.* 800), but it was constantly supplemented throughout the Middle Ages by new additions from diocesan or provincial areas. It was not until 1634 that the Roman see gained complete control over the veneration and canonization of saints in the Roman Catholic churches subject to its jurisdiction.

Before the toleration of the Christian Church under Constantine (AD 312), the several churches commemorated only their martyrs, on the anniversaries of their deaths, commonly called their *natale,* or birthdays, with rites similar to those of Easter. By giving up life for their faith, often after cruel tortures, the martyrs were the supreme examples of the imitation of Christ. The earliest attested institution of such an anniversary is recorded in the *Martyrdom of Polycarp* of Smyrna (*c.* 155). The oldest Roman calendar of the martyrs reaches only to the beginning of the 3rd century and includes the joint martyrdom of the church's apostolic founders saints Peter and Paul (June 29), a feast apparently instituted in the year 258.

Veneration of martyrs and the relics of saints

After the age of the martyrs, the calendars continued to be enriched by entries of eminent bishops, teachers, ascetics, and missionaries. Other new feasts were associated with the transfer of the relics of saints to sumptuous shrines or churches dedicated in their honour. A precedent of great influence was the feast of dedication of the Church of the Holy Sepulchre (or Anastasis, "resurrection") at Jerusalem, on Sept. 14, 335, where the discovered tomb and cross of Christ were enshrined on the supposed site of his victory over death. The feast is popularly called Holy Cross Day. From the 4th to the 6th century many "inventions" or discoveries of relics were produced and fictitious "Acts" written to promote the cults of apostles, evangelists, and hitherto unknown martyrs of earlier times.

In the late 4th century a feast of All Martyrs was observed by the East Syrians on May 13 and by the West Syrians and Byzantines on the Sunday after Pentecost. Pope Boniface IV received from the emperor Phocas (reigned 602–610) the Pantheon at Rome, which he dedicated on May 13 to St. Mary and All Martyrs. The Feast of All Saints at Rome on November 1 was promulgated by Pope Gregory IV in 835, in place of the May festival. Some authorities believe this festival to be of Irish origin; others relate it to a chapel of All Saints in St. Peter's Basilica established by Pope Gregory III (reigned 731–741).

Veneration of Mary

Liturgical feasts in honour of Mary—related to the incarnation cycle—developed in the East after the third ecumenical Council of Ephesus in 431, where she was declared to be Theotokos ("God-bearer"). At Rome the earliest special commemoration was on the Octave of Christmas, but Pope Sergius I (reigned 687–701), an Easterner, introduced to Rome her four major feasts: her Nativity (September 8); Purification of the Blessed Virgin Mary (February 2, with its procession of candles—hence "Candlemas"); Annunciation (March 25); and Assumption (August 15).

LITURGICAL COLOURS

The early Christians had no system of colours associated with the seasons, nor do the Eastern Churches to this day have any rules or traditions in this matter. The Roman emperor Constantine gave Bishop Macarius of Jerusalem a "sacred robe . . . fashioned with golden threads" for use at baptisms (Theodoret, *Ecclesiastical History,* Book II, chapter 23). Toward the end of the 4th century, references are made to shining white garments worn by celebrants at the Eucharist (*Apostolic Constitutions,* Book VIII, chapter 12; Jerome, *Dialogi contra Pelagianos,* Book I, chapter 29). Inventories of Frankish churches in the 9th century reveal a variety of colours used for vestments, but without any particular sequence for their use; but the *Ordo* of St. Amand of the same period refers specifically to dark vestments at the major litanies and black ones at the Feast of Purification (February 2).

The modern colour sequence of the Roman Catholic Church was first outlined in Pope Innocent III's treatise *De sacro altaris mysterio* (Book I, chapter 65, written before his election as pope in 1198), though some variations are admitted. White, as a symbol of purity, is used on all feasts of the Lord (including Maundy Thursday and All Saints') and feasts of confessors and virgins. Red is used at Pentecost, recalling the fiery tongues that descended upon the Apostles when they received the Holy Spirit, and also at feasts of the Holy Cross, Apostles, and martyrs, as symbol of their bloody passions (sufferings and deaths). Black is used as a symbol of mourning on days of fasting and penitence and at commemorations of the departed—but violet, symbolizing the mitigation of black, is allowed during Advent and Lent. Green is used on other days, without special significance, as a compromise colour distinguished from white, red, and black. Innocent's symbolism is based upon allegorical (symbolic) interpretations of colours and flowers mentioned in Scripture, especially in the Song of Solomon.

In the later Middle Ages other colours were used in various churches, such as blue for certain feasts of the Virgin Mary, and rose (a mitigation of violet) on the third Sunday in Advent and the fourth Sunday in Lent. The missal of Pope Pius V in 1570 prescribed the sequence of Innocent III, with rose on the two Sundays mentioned. In 1868 the Congregation of Rites allowed the use of gold vestments in place of white, red, and green. Medieval English uses showed much variation, but the predominant principle was use of the finest vestments, of whatever colour, on great feasts, and others on lesser days of importance. In the Use of Sarum, white, red, and blue were the primary colours; but in Lent an unbleached cloth was customary, changing to deep red during the two weeks before Easter.

Anglican and Lutheran churches have in recent times generally followed the Roman sequence, although some Anglican churches have restored the colours of the Use of Sarum. In the liturgical experiments since World War II, the sequences and symbolism inherited from the Middle Ages are being abandoned, and a greater freedom is evident in paraments (vestments and hangings), with increasing variety and combinations of colours, especially on festal occasions. (M.H.S.)

Canon law

Canon law—which in its wider sense includes precepts of divine law, natural or positive, incorporated in various canonical collections or codes—is in this article defined as that body of rules and regulations (canons) concerning the behaviour and actions of individuals and institutions within certain Christian churches, which have, through proper ecclesiastical authority, defined and codified such rules. Though canon law is historically continuous from the early church to the present, it has, as a result of doctrinal and ecclesiastical schisms, developed differing, though often similar, patterns of codification and norms in the various churches that have incorporated it into their ecclesiastical frameworks. The canon law of the Eastern and Western churches was much the same in form until these two groups of churches separated in the Schism of 1054. In Eastern Christianity, however, because of doctrinal and nationalistic disputes during the 5th to 7th centuries, several church groups (especially non-Greek) separated themselves from the nominal head of Eastern Christianity, the patriarch of Constantinople, and developed their own bodies of canon law, often reflecting nationalistic concerns.

Canon law in the Western churches after 1054 developed without interruption until the Reformation of the 16th century. Though other churches of the Reformation rejected the canon law of the Roman Catholic Church, the Church of England retained the concept of canon law and developed its own type, which has acceptance in the churches of the Anglican Communion.

Canon law has had a long history of development throughout the Christian Era. Not a static body of laws, it reflects social, political, economic, cultural, and ecclesiastical changes that have taken place in the past two millennia. During periods of social and cultural upheaval the church has not remained unaffected by its environment. Thus, canon law may be expected to be involved in the far-reaching changes that have come to be anticipated in the modern world.

NATURE AND SIGNIFICANCE

A church is defined as a community founded in a unity of faith, a sacramental fellowship of all members with Christ as Lord, and a unity of government. Many scholars assert that a church cannot exist without authority—*i.e.,* binding rules and organizational structures—and that religion and law are mutually inclusive. Thus the calling of a church leader to office is regarded as important in the organizational structure and, like every other fundamental vocation in the churches that accept the validity of canon law, it is also viewed as sacramental and as linked to the priesthood—which, in turn, involves a calling to leadership in liturgy and preaching. According to Roman Catholic belief, the mission of the college of Apostles (presided over by Peter in the 1st century AD) is continued in the college of bishops, presided over by the pope. Other churches may accept this view, without at the same time accepting the authority of the pope. The validity of canon law thus rests on an acceptance of this sacramental view

Necessity of authority

and of the transmitted mission of the Apostles through the bishops.

Historical and cultural importance of canon law. Canon law has functioned in different historical periods in the organization of the church's liturgy, preaching, works of charity, and other activities through which Christianity was established and spread in the Mediterranean area and beyond. Canon law, moreover, had an essential role in the transmission of Greek and Roman jurisprudence and in the reception of Justinian law (Roman law as codified under the sponsorship of the Byzantine emperor Justinian in the 6th century) in Europe during the Middle Ages. Thus it is that the history of the Middle Ages, to the extent that they were dominated by ecclesiastical concerns, cannot be written without knowledge of the ecclesiastical institutions that were governed according to canon law. Medieval canon law also had a lasting influence on the law of the Protestant churches. Numerous institutions and concepts of canon law have influenced the secular law and jurisprudence in lands influenced by Protestantism: *e.g.,* marriage law, the law of obligations, the doctrine of modes of property acquisition, possession, wills, legal persons, the law of criminal procedure, and the law concerning proof or evidence. International law owes its very origin to canonists and theologians, and the modern idea of the state goes back to the ideas developed by medieval canonists regarding the constitution of the church. The history of the legal principles of the relation of *sacerdotium* to *imperium*—*i.e.,* of ecclesiastical to secular authority or of church to state—is a central factor in European history.

Problems in the study of canon law and its sources. Because of the discontinuity that has developed between church and state in modern times and the more exclusively spiritual and pastoral function of church organization, scholars in canon law are searching for a recovery of vital contact among canon law and theology, biblical exegesis (critical interpretive principles of the Bible), and church history in their contemporary forms. Canon-law scholars are also seeking a link with the empirical social sciences (*e.g.,* sociology, anthropology, and other such disciplines), which is required for insight into and control of the application of canon law. The study of the history of canon law calls not only for juridical and historical training but also for insight into contemporary theological concepts and social relationships. Many sources, such as the documents of councils and popes, are often uncritical and found only in badly organized publications, and much of the material exists only in manuscripts and archives; frequently the legal sources contain dead law (*i.e.,* law no longer held valid) and say nothing about living law. What does and does not come under canon law, what is or is not a source of canon law, which law is universal and which local, and other such questions must be judged differently for different periods.

The role and function of canon law

The function of canon law in liturgy, preaching, and social activities involves the development and maintenance of those institutions that are considered to be most serviceable for the personal life and faith of members of the church and for their vocation in the world. This function is thus concerned with a continual adaptation of canon law to the circumstances of the time as well as to personal needs.

HISTORY

The formative period: origins to Gratian (c. 1140). The early church was not organized in any centralized structure. Over a long period of time, there developed patriarchates (churches believed to have been founded by Apostles) and bishoprics, the leaders of which—either as monarchical bishops or as bishops with shared authority (*i.e.,* collegiality)—issued decrees and regulatory provisions for the clergy and laity within their particular jurisdictions. After the emperor Constantine granted tolerance to Christians within the Roman Empire, bishops from various sees—especially from the eastern part of the empire—met in councils (*e.g.,* the ecumenical Council of Nicaea). Though these councils are known primarily for their consideration of doctrinal conflicts, they also ruled on practical matters (such as jurisdictional and institutional concerns), which were set down in canons. In the West, there was less imperial interference, and the bishop of Rome (the pope) gradually assumed more jurisdictional authority than his counterpart (the ecumenical patriarch of Constantinople) in the East. Throughout this period there were often conflicting canons, since there were many independently developed canonical collections and no centralized attempt to bring order out of the many collections until the Middle Ages.

Eastern churches. In addition to the New Testament, the writings of the Apostolic Fathers (second generation of Christian writers) and the pseudo-apostolic writings (documents attributed to but not written by the Apostles) contain the oldest descriptions of the customs existing in the East from the 2nd century until the 5th. The sources of all the others are the *Doctrina duodecim Apostolorum* (*Doctrine of the Twelve Apostles,* 2nd century?), the *Didascalia Apostolorum* (*Teaching of the Apostles,* 3rd century), and the *Traditio Apostolica* (*Apostolic Tradition*), attributed to Hippolytus, written in Rome about AD 220 but far more widely distributed in the East. From these documents, the *Constitutiones Apostolicae* (*Apostolic Constitutions*), in which 85 *Canones Apostolicae* (*Apostolic Canons*) were included, were composed about AD 400.

During the period that followed Constantine's grant of religious toleration, many synods held in the East legislated, among other things, various disciplinary rules, or *canones.* In addition to and in place of the law of custom, written law entered the scene. An ecumenical Council of Chalcedon (AD 451) possessed a chronological collection of the canons of earlier councils. This *Syntagma canonum* ("Body of Canons"), or *Corpus canonum orientale* ("Eastern Body of Canons"), was subsequently complemented by the canons attributed to other 4th- and 5th-century councils, canonical letters of 12 Greek Fathers and of the 3rd-century Latin bishop of Carthage, Cyprian, and the *Constitutiones Apostolicae.* With the exception of the last, the Trullo (supplementary) Council of Quinisextum, or the fifth and sixth councils (692), accepted this complex, along with its own canons, as the official legal code of the Eastern churches. The canons of the second ecumenical Council of Nicaea (787) and of the two councils (861 and 879–880) under Photius, patriarch of Constantinople, were added to that.

Systematic collections and the science of canon law

The systematic collections—and there were many of them—contained either canons of councils or ecclesiastical laws (*nomoi*) of the emperors or both together (nomocanons). The first known Greek collection of canons that is preserved is the *Collectio 50 titulorum* ("Collection of 50 Titles"), after the model of the 50 titles of the work known as the *Pandecta* ("Accepted by All") composed by the patriarch John Scholasticus about 550. He composed from the Novels (*Novellae constitutiones post Codicem*) of Justinian the *Collectio 87 capitulorum* ("Collection of 87 Chapters"). The *Collectio tripartita* ("Tripartite Collection"), from the end of the 6th century and composed of the entire Justinian ecclesiastical legislation, was the most widely distributed. The nomocanons were expressions of the fusion of imperial and church authority. The *Nomocanon 50 titulorum* ("Canon Law of 50 Titles") from about 580, composed of the works of John Scholasticus, remained in use until the 12th century. The edition of the *Nomocanon 14 titulorum* ("Canon Law of 14 Titles") was completed in 883 and accepted in 920 as law for the entire Eastern Church.

The science of canon law was pursued together with the study of secular law, especially in the schools in Constantinople and Beirut. The *Scholia* (commentaries) on the *Basilica,* a compilation of all of imperial law from the time of Justinian, promulgated by the Byzantine emperor Leo VI (reigned 886–912), influenced the method of commenting on and teaching canon law. The best-known commentators in the 12th century were Joannes Zonaras and Theodore Balsamon. Matthew Blastares composed his *Syntagma alphabeticum* ("Alphabetical Arrangement"), an alphabetic manual of all imperial and church law, in 1335 from their works.

Independent churches of Eastern Christianity. The churches of Eastern Christianity that separated from the

patriarchal see of Constantinople over a period of several centuries, but primarily during the 5th and 6th centuries, developed bodies of canon law that reflected their isolated and—after the Arab conquests in the 7th century—secondary social position. Among these churches are the Syrian Orthodox Patriarchate of Antioch (in Syria), the Ancient Church of the East (the Assyrians), the Armenian Apostolic Church, and the Coptic Orthodox Church (in Egypt). Another independent church is the Ethiopian Orthodox Church.

Though these churches developed an extensive body of canon law throughout their histories, Western knowledge of their canon law has been very scant. In the 20th century, however, more than 300 manuscripts dealing with canon law were found in various isolated monasteries and ecclesiastical libraries of the Middle East by Arthur Vööbus, an Estonian-American church historian. These manuscripts cover the period from the 3rd to the 14th century and deal with ecclesiastic regulations of the Syrian churches. Included among these manuscripts are the following: "The Canons of the Godly Monastery of St. Mār Mattai" (630), 26 in number, concerning the jurisdiction of the metropolitan (an archbishop) over the monastery; "The Canons of the Holy Qyriaqos, Which the Patriarch Composed and the Synod of the Saints and Bishops with Him" (794), containing 46 canons dealing with ecclesiastical and moral discipline and with liturgical, cultic, and monastic matters; and "The Canons Which Were Composed by the Holy Synod Which Assembled in Bēt Mār Šīlā [in the region] of Serūg, and Which Consecrated Mār Dionysios as Patriarch of Antioch, the City of God" (896), which originally contained 40 canons, though only 25 remain, dealing with the election and examination of candidates for the hierarchy and clergy, the conduct of priests, marriage, pagan influences, and religious and ecclesiastical duties. These canonical collections come from the West Syrian churches. Other canonical collections of the East Syrian churches were published in the early part of the 20th century.

Western churches. From about 300 until about 550, canon law in Western churches had a certain unity through the acceptance of the Eastern and North African councils and the binding factor of the papal decretal law (answers of popes to questions of bishops in matters of discipline), which did not exist in the East. The African canons, like the Eastern canons at Chalcedon, were read out at the councils of Carthage and, if confirmed, included in the Acts, which contained the newly enacted canons. Thus, at the third Council of Carthage (397), the Compendium of the Council of Hippo (393) was included. The collection of the 17th Council of Carthage (419) was soon accepted in all of the East and West. In Spain the canons of Nicaea I (325) and Chalcedon (451) and also African and south Gallican canons and Roman decretals were taken over, as well as their own canons, but the later *Hispana* (Spanish collection) crowded out all earlier collections. The Council of Elvira (295–314) in Spain was the first that set up a more complete legislation, followed by Gaul in the first Council of Arles in 314. Texts from the East, Spain, and Rome, including the *Collectio Quesnelliana* (an early 6th-century canonical collection named for its publisher, the 17th-century Jansenist scholar Pasquier Quesnel), circulated there. Gennadius, a priest from Marseille, in about 480 wrote the *Statuta ecclesiae antiqua* ("Ancient Statutes of the Church"), principally inspired by the *Constitutiones Apostolicae.* A tendency toward the unification of canon law revealed itself most clearly in Italy against the disintegrating situation that existed between the Eastern and Western churches—*i.e.,* the so-called Acacian Schism (484–519), occasioned by the patriarch Acacius of Constantinople and the emperor Zeno's neglect of the legislation of the Council of Chalcedon—and the breakup of the Western Empire soon after the fall of Rome (476), at the time of the 30-year "Gelasian renaissance," beginning during the reign of Pope Gelasius I. There also existed in Rome translations of Eastern councils: *Vetus Romana, Versio Hispana* ("Ancient Roman, Spanish Version"), *Isidoriana, versio Prisca* ("The Isidorian, Priscan Version"), and *Itala* ("Italian"). By far the most important is that of the *Liber canonum* ("Book of Canons") of the 6th-century Roman theologian Dionysius Exiguus, about 500. The first two versions contain 50 *Canones Apostolorum,* Greek canons, and the African canons of the 17th Council of Carthage. Dionysius Exiguus also composed a *Liber decretorum* ("Book of Decretals") from Pope Siricius to Pope Anastasius II. Together, the books form the *Corpus* ("Body") or *Codex canonum* ("Code of Canons").

Development of canon law in western Europe

Until the end of the 7th century a greater decentralization and less mutual contact occurred in the separate German kingdoms. Elements of German law found their way into Roman canon law. The *Collectio Avellana* ("Avellan Collection"), written in Rome about 555, which was a Western nomocanon; the *Collectio Novariensis* ("Novarien Collection"); and the *Epitome Hispanica* ("Spanish Abridgment") entered Italy from Spain. In Africa the first, albeit primitive, systematic collections appeared. These included the *Breviatio canonum* ("Abridgment of Canons") of (Fulgentius) Ferrandus, deacon of the Church of Carthage (*c.* 546), and the *Concordia canonum Cresconii* ("Harmony of the Canons of Cresconius," a 6th- or 7th-century author), a systematic compilation of the *Dionysiana,* subsequently found in different manuscripts in Gaul. There the collections were local ones: every cathedral and monastery had its own *liber canonum.* The church of Arles, the metropolis of southern Gaul, had the *Liber auctoritatum* ("Book of Authorities"; *i.e.,* legal texts), a nomocanon of its privileges. The first systematic Gallic *Collectio Andegavetis* ("Andegavenan Collection"), from the end of the 7th century, was an attempt to unite the ancient law with the native.

Decentralization in the German kingdoms

In Spain, after the conversion of King Recared in 587, the church of the Visigothic kingdom became a well-knit national church with a classical provincial structure under metropolitan jurisdiction, closely linked to the crown. The national councils of Toledo preserved the unity of law and respect for the ancient law. The *Capitula* ("Chapters") of Martinus, bishop of Braga (*c.* 563), was included completely in the *Hispana* and was also copied outside Spain. The *Collectio Novariensis* was related to the *Epitome Hispanica,* the code of the hierarchy that was temporarily halted at the fourth Council of Toledo (633). The *Hispana* was recognized by popes Alexander III and Innocent III as the authentic *corpus canonum* of the Spanish church. Shortly before the *Hispana,* systematic indices (called *tabula*) were written and were subsequently expanded into *excerpta* ("excerpts") and finally into complete texts, the *Hispana systematica* ("Systematic Spanish [Code]"). After the 10th century, the *Hispana* was also called the *Isidoriana,* attributed to Isidore of Seville, a Spanish encyclopaedist and theologian, who was the author of the *Etymologiae* ("Etymologies"), a universally distributed early medieval book of doctrine.

The most disparate picture is offered by the church in the British Isles. The church there was concentrated around heavily populated monasteries, and discipline outside them was maintained by means of a new penitential practice. In place of ancient canons about public penance, the clergy and monks used *libri poenitentiales* ("penitential books"), which contained detailed catalogs of misdeeds with appropriate penances. They were private writings without official authority and with very disparate content. From the monasteries founded in Europe by the Irish monk St. Columban and missionaries of Anglo-Saxon background, the *libri poenitentiales* spread throughout the continent, where once again new versions emerged. The *Collectio Hibernensis* ("Hibernian [or Irish] Collection"), of about 700, used texts from Scripture, mainly from the Old Testament, for the first time in canonical collections, and texts from the Greek and Latin early Church Fathers in addition to canons. The *Liber ex lege Moysi* ("Book from the Law of Moses"), an Irish work, drew exclusively from the Pentateuch.

The Carolingian reform

The reorganization of the Frankish church began with the Carolingian reform in the middle of the 8th century. The canon law was set down especially in the *Capitularia ecclesiastica* ("Ecclesiastical Articles") of the prince, as well as in the *Capitularia missionum* ("Mission Articles"; *i.e.,* instructions given by the prince to the bishops and

abbots who visited in his name). The *Capitularia* ("Short Articles") of Charlemagne, the founder of the Holy Roman Empire, and his son, the emperor Louis the Pious, were collected in 827 by the abbot Ansegisus. Following this model the bishops composed terse *capitula,* the oldest known diocesan statutes, for their clergy. The penance books were condemned and replaced by new ones that were more closely related to tradition. The reception of the *Dionysiana* and the *Hispana* is of importance for the transmission of the text and for the Carolingian cultural renaissance. In 774 Charlemagne received from Pope Adrian I a completed *Dionysiana,* the *Dionysiana-Hadriana,* which was accepted at a national synod in Aachen in 802 but never was adopted as an official national code. About 800 the *Hadriana* and the *Hispana* were developed into a systematic whole, the *Dacheriana* (canonical collection named for its 17th-century publisher, a French scholar, Jean-Luc d'Achéry)—the principal source of the collections before 850—which was of influence until the Gregorian reform in the 11th century.

After Louis the Pious, the central power among the Franks was increasingly divided among counts and barons. German law—which linked the right to govern with land ownership, without distinction between public and private law—expressed itself in the medieval forms of the system of private churches. This northern law looked upon dioceses, churches, and monasteries—with their rights and privileges—as lucrative possessions that deserved to be confiscated, by fraudulent means if necessary.

Such situations became the occasion in about 850 for the massive falsifications (*i.e.,* forgeries) of the pseudo-Isidorian collections: the *Hispana Augustodunensis* ("Spanish Collection of Autun"), the *Capitula Angilramni* ("Chapters of Angilramnus," bishop of Metz), the *Capitularia Benedicti Levitae* ("Frankish Imperial Laws of Benedict the Levite," a fictitious name), and the *Pseudo-Isidorian Decretals.* The central goal of the anonymous Frankish group of authors of these collections was to strengthen the position of the bishops and to rectify the poor condition of ecclesiastical–state affairs. This was accomplished by means of falsified and forged texts that were attributed to the esteemed authority of the old law (*i.e.,* the popes) and the Carolingian princes. They did not have much influence on the real development of canon law, although later collections drew from them abundantly. Only the Magdeburg Centuriators, authors of the *Centuries,* a 16th-century Lutheran church history, denied the genuineness of all the decretals of pseudo-Isidore; the lack of authenticity of the other three works was discovered later.

Several collections appeared before AD 1000. About 882 decretals were organized in the *Collectio Anselmo dedicata* ("Collection Dedicated to Anselm"), a papally oriented, systematic work from northern Italy. In Germany the *Libri duo de synodalibus causis et disciplinis ecclesiasticis* ("Two Books Concerning Synodical Causes and Church Discipline") of Regino, abbot of Prüm (906), was a bishops' manual for the judicial interrogation of jurymen during a visitation; and in France appeared the collection of Abbon, abbot of Fleury (*c.* 996), which defended the legal position of his monastery against the king and bishop. Intended as a doctrinal book for the young cleric, the Decree of Burchard—bishop of Worms from 1000 to 1025—became the canon-law manual in the cathedral schools and in the curias (administrative bureaucracies) of bishops and abbots in Germany, France, and Italy. Burchard was a promoter of moderate imperial reform. He did not reject the system of private churches; he only rejected the misuses proceeding from it, such as simony (buying or selling church offices) and the violation of celibacy.

The Gregorian reformation

The slogans of the Gregorian reformation, initiated by Pope Gregory VII (reigned 1073–85), were *libertas Ecclesiae* ("liberty of the church") and *puritas Ecclesiae* ("purity of the church"). These slogans advocated freedom from the system of private churches on all levels; freedom from papal dependence on the Roman nobility and emperor; freedom from dependence of the village priest on his *senior* (the beginning of the fight against investiture); and purity from simony and from the total collapse of celibacy (which was exhibited in the practice of hereditary parishes and bishoprics). Fundamental principles of Gregorian canon law included those stipulating that only canon law that is given or approved by the pope is valid; papal legates (representatives) stand above the local hierarchies and preside over synods; for possession of every ecclesiastical office, choice and appointment by church authorities is demanded, along with the exclusion of lay investiture; every form of simony makes the appointment invalid; and the faithful must boycott the services of married priests. New material was sought, especially for the confirmation of papal primacy, in archives and libraries. The principal new sources were the *Breviarium* of Cardinal Atto (*c.* 1075), the *Dictatus Papae* ("Dictates of the Pope") of Gregory VII (*c.* 1075), the *Collectio 74 titulorum,* or "Collection of 74 Titles" (1074–76), the collection of Bishop Anselm of Lucca (*c.* 1083) and that of Cardinal Deusdedit (*c.* 1085), and the *Liber de vita Christiana* ("Book Concerning the Christian Life") of Bonizo, bishop of Sutri (*c.* 1090).

The investiture battle over the conflicting asserted rights of lay or ecclesiastical officials to invest a church official with the symbols of his spiritual office ended in France, England, and Germany (Concordat of Worms, 1122) in compromises. Gregorian law, which now seems too strict, had to be reconciled with the established traditions. Ivo, bishop of Chartres from 1091 to 1116, contributed to the settlement of the investiture problem by his political activities; his extended correspondence; and his three law collections, *Tripartita* ("Tripartite Collection"), *Decretum* ("Decrees"; *i.e.,* collection of decrees or canons), and *Panormia* (collections of "All the Laws"), the last two practically a fusion of Burchard's Decree with Gregorian law. The famous Prologue, written by Ivo for either the *Decretum* or the *Panormia,* indicated for the first time a method by which the bishop must handle the conflicting strict and liberal texts, with *justitia* ("justice") or *misericordia* ("mercy"). Bernold of Constance, in his little tractates, written between 1070 and 1091, listed several criteria for the reconciliation of conflicting texts, including authenticity of the text; identity of the author; difference between law, counsel, and dispensation, between universal and local law, of time and place; and different meanings of a word. A Liège (Belgium) canon lawyer, Alger, in his *Liber de misericordia et justitia,* or "Book Concerning Mercy and Justice" (*c.* 1105), applied Ivo's criteria to the problem of the effect of sacraments administered by heretics and persons guilty of simony. The great medieval theologian Abelard developed the method of reconciling texts that are for or against a theological position in his *Sic et non,* or "Yes and No" (1115–17). The same methods were applied by the first writers of glosses (commentaries or interpretations) at the law school in Bologna on the *Pandecta* of Justinian, which was rediscovered in about 1070.

The Corpus Juris Canonici (c. 1140–c. 1500). About 1140 the monk John Gratian completed his *Concordia discordantium canonum* ("Harmony of Contradictory Laws"), later called the *Decretum Gratiani* ("Gratian's Decree"); it became not only the definitive canonical collection of the entire preceding tradition but also a systematic application of the scholastic method to all legal material. The *Decretum* dealt with the sources of the law, ordinations, elections, simony, law of procedure, ecclesiastical property, monks, heretics, schismatics, marriage, penance, and sacraments and sacramentals. Primitive as it was, it provided a foundation for systematic compilation of the legal material by the canonists and for the expansion of decretal law. It provided a basis for the education in canon law that began in the schools of Bologna, Paris, Orléans, Canterbury, Oxford, Padua, and elsewhere. It was accepted everywhere in the ecclesiastical administration of justice and government.

Collections of decretals

From the time that the Gregorian reformation introduced a more centralized ecclesiastical administration, the number of appeals to Rome and the number of papal decisions mounted. New papal laws and decisions, called decretals, first added to Gratian's *Decretum,* were soon gathered into separate collections, of which the best known are the *Quinque compilationes antiquae* ("Five Ancient Compilations"). The first, the *Breviarium extravagantium*

("Compendium of Decretals Circulating Outside"; *i.e.,* not yet collected) of Bernard of Pavia, introduced a system inspired by the codification of Justinian, a division of the material into five books, briefly summarized in the phrase *judex* ("judge"), *judicium* ("trial"), *clerus* ("clergy"), *connubium* ("marriage"), *crimen* ("crime"). Each book was subdivided into titles and these in turn into *capitula,* or canons. This system was taken over by all subsequent collections of decretals. These compilations were the foremost source of the *Liber extra* ("Book Outside"; *i.e.,* of decretals not in Gratian's Decree) or *Liber decretalium Gregorii IX* ("Book of Decretals of Gregory IX"), composed by Raymond of Peñafort, a Spanish canonist, and promulgated on Sept. 5, 1234, as the exclusive codex for all of canon law after Gratian. On March 3, 1298, Pope Boniface VIII promulgated *Liber sextus* ("Book Six"), composed of official collections of Innocent IV, Gregory X, and Nicholas III, and private collections and decretals of his own, as the exclusive codex for the canon law since the *Liber extra.* The *Constitutiones Clementinae* ("Constitutions of Clement") of Pope Clement V, most of which were enacted at the Council of Vienne (1311–12), were promulgated on Oct. 25, 1317, by Pope John XXII, but they were not an exclusive collection. The *Decretum Gratiani,* the *Liber extra, Liber sextus,* and *Constitutiones Clementinae,* with the addition of two private collections, the *Extravagantes* of John XXII and the *Extravagantes communes* ("Decretals Commonly Circulating"), were printed and published together for the first time in Paris in 1500. This entire collection soon received the name *Corpus Juris Canonici* ("Corpus of Canon Law").

The science of canon law was developed by the writers of glosses, the commentators on the Decree of Gratian (decretists), and the commentators on the collections of decretals (decretalists). Their glosses were based on the system used by Gratian: next to the texts of canons parallel texts were noted, then conflicting ones, followed by a *solutio* ("solution"), again with text references. In connection with this the glosses of other canonists were also introduced. In this way the *apparatus glossarum,* continuous commentaries on the entire book, arose. The *glossa ordinaria* ("ordinary explanation") on the different parts of the *Corpus Juris Canonici* was the apparatus that was used universally in the schools. After the classical period of the glossators (12th–14th century), terminated by the work of a lay Italian canonist, John Andreae (*c.* 1348), followed that of the post-glossators. In the absence of new legislation in the time of the Babylonian Captivity (1309–77), when the papacy was situated at Avignon, Fr., and the Great Schism (1378–1417), when there were at least two popes reigning simultaneously, the commentaries on decretals continued, but with a larger production of special tracts; *e.g.,* regarding the laws of benefices and marriage and of *consilia* (advice about concrete legal questions).

From the Council of Trent (1545–63) to the Codex Juris Canonici (1917). *The end of decretal law.* Toward the end of the Middle Ages decretal law ceased to govern. Medieval Christian society became politically and ecclesiastically divided, according to the principle of *cujus regio, ejus religio* (Latin: "whose region, his religion"; *i.e.,* the religion of the prince is the religion of the land). In Protestant areas the former Roman Catholic church buildings and benefices were taken over by other churches; and even in the lands that remained Catholic the churches found themselves in an isolated position as secularization forced the churches to reorganize. With the end of feudalism, canon law dealing with benefices, chapters, and monasteries, which were closely bound to the feudal structure, changed. The territorial, material, and economic character of canon law and the decentralization allied with it disappeared. The decision of the reform councils from Pisa (1409) until the fifth Lateran Council (1512–17) affected, in particular, benefices, papal reservations, taxes, and other such ecclesiastical matters. In the same period various concordats (agreements) permitted the princes to intervene in the issue of ecclesiastical benefices and property. Canon law took on a more defensive character, with prohibitions regarding books, mixed marriages, participation of Roman Catholics in Protestant worship and vice versa, education of the clergy in seminaries, and other such areas of concern.

At the Roman Catholic reform Council of Trent (1545–63) a new foundation for the further development of canon law was expressed in the *Capita de reformatione* ("Articles Concerning Reform"), which were discussed and accepted in 10 of the 25 sessions. Papal primacy was not only dogmatically affirmed against conciliarism (the view that councils are more authoritative than the pope) but was also juridically strengthened in the conduct and implementation of the council. The central position of the bishops was recovered, over against the decentralization that had been brought about by the privileges and exemptions of chapters, monasteries, fraternities, and other corporate bodies that sprang from Germanic law, as well as caused by the rights granted to patrons. In practically all matters of reform the bishops received authority *ad instar legati S. Sedis* ("like delegates of the Holy See"). Strict demands were made for admission to ordination and offices; measures were taken against luxurious living, nepotism, and the neglect of the residence obligation; training of the clergy in seminaries was prescribed; prescriptions were given about pastoral care, schools for the young, diocesan and provincial synods, confession, and marriage; the right to benefices was purified of misuse; and the formalistic law of procedure was simplified.

The council gave the duty of execution of the reform to the pope. On Jan. 26, 1564, Pius IV confirmed the decisions, reserved to himself their interpretation and execution, and on Aug. 2, 1564, established the Congregation of the Council for that purpose. The congregations of cardinals, which proceeded from the former permanent commissions of the *consistorium* (the assembly of the pope with the College of Cardinals), were organized by Pope Sixtus V in 1587. Since then the administrative apparatus of the Curia has consisted of congregations of cardinals together with courts and offices. This apparatus made it possible for the Latin Church to acquire a uniform canon law system that was developed in detail.

The congregations of cardinals

Law for the missions. Expansion of the church brought with it expansion of the ordinary hierarchical episcopal structure. This was true also for the new colonies under the right of patronage of the Spanish and Portuguese kings. In the other mission areas and in the areas taken over by the Protestants, where the realization of the episcopal structure and the decretal law adopted by Trent was not possible, the organization of mission activity was taken from missionaries and religious orders and given to the Holy See. The Sacred Congregation for Propagation of the Faith (the Propaganda) was established for this purpose in 1622. Missionaries received their mandate from Rome; the administration was given over to apostolic vicars (bishops of territories having no ordinary hierarchy) and prefects (having episcopal powers, but not necessarily bishops) who were directly dependent on the Propaganda, from which they received precisely described faculties. A new, uniform mission law was created, without noteworthy native influence; this sometimes led to conflict, such as the Chinese rites controversy in the 17th and 18th centuries over the compatibility of rites honouring Confucius and ancestors with Christian rites.

The first Vatican Council (1869–70) strengthened the central position of the papacy in the constitutional law of the church by means of its dogmatic definition of papal primacy. Disciplinary canons were not enacted at the council; but the desire expressed by many bishops that canon law be codified did have influence on the emergence and content of the code of canon law.

The Codex Juris Canonici (1917). Since the closing off of the *Corpus Juris Canonici* there had been no official or noteworthy private collection of the canon law, except for the constitutions of Pope Benedict XIV (reigned 1740–58). The material was spread out in the collections of the *Corpus Juris Canonici* and in the generally very incomplete private publications of the *acta* of popes, of general and local councils, and the various Roman congregations and legal organs, which made canon law into something unmanageable and uncertain. The need for codification was recognized even more because of the fact that since

the end of the 18th century, secular law had undergone a period of great codification. Several private attempts to do this had met with little success.

On March 19, 1904, Pius X announced his intention to complete the codification, and he named a commission of 16 cardinals, with himself as chairman. Bishops and university faculties were asked to cooperate. The schemata of the five books that were prepared in Rome—universal norms, personal law, law of things, penal law, and procedural law—were proposed in the years 1912–14 to all those who would ordinarily be summoned to an ecumenical council, and with their observations were then reworked in the cardinals' commission. The entire undertaking and all the drafts were under the papal seal of secrecy and were not published. Meanwhile, Pius X introduced various reforms that were to a great degree the results of the commission's work. In July 1916 the preparations for the *Codex Juris Canonici* ("Code of Canon Law") were completed. The code was promulgated on Pentecost Sunday, May 27, 1917, and became effective on Pentecost Sunday, May 19, 1918.

Reorganization of the Code of Canon Law

In contrast to all earlier official collections this code was a complete and exclusive codification of all universal church law then binding in the Latin Church. Out of fear of political difficulties, a systematic handling of public church law, especially what concerned the relations between church and state, was omitted. Its main purpose was to offer a codification of the law, and only incidentally adaptation, and so it introduced relatively little that was new legislation. The 2,414 canons were divided into five books that no longer followed the system of the collections of decretals but did follow that of the Perugian canonist Paul Lancelotti's *Institutiones juris canonici* (1563; "Institutions of Canon Law"), which in turn went back to the division of the 2nd-century Roman lawyer Gaius' *Institutiones*—one section on persons, two sections on things, and one section on actions—and was based on the fundamental idea of Roman law; *i.e.,* subjective right. In some editions the sources that were used by the editors were indicated at the individual canons. With the publication of the codex these sources belonged to the history of the law. Older general and particular law, in conflict with the codex, was given up and, insofar as it was not in conflict with it, served only as a means for interpreting the code. The old law of custom in conflict with the code and expressly reprobated by it was rendered null; when not reprobated and 100 years old or immemorial it could be allowed by ordinaries for pressing reasons. Acquired rights and concordats in force remained in force. With this change, an independent science of the history of canon law became necessary, in addition to the dogmatic canonical science of canon law on the basis of the code.

In order to ensure the unity of the codification and the law, a commission of cardinals was established on Sept. 15, 1917, for the authentic interpretation of the new code. At the same time it was decided that the cardinals' congregations should no longer make new general decrees but only instructions for the carrying out of the prescriptions of the code. Should a general decree appear necessary, it was determined, the commission would formulate new canons and insert them into the code. Neither of these decisions was carried out. Only two canons were altered and congregations promulgated numerous general decrees. New papal legislation complemented and altered the law of the code.

The Eastern churches in union with Rome. Catholic Eastern churches (churches in union with the Roman Catholic Church) retain their own traditions in liturgy and church order, insofar as these are not considered to be in conflict with the norms taken by Rome to be divine law. In 1929 Pius XI set up a commission of cardinals for the codification of canon law valid for all Uniate churches in the East. In the following year a commission was established for the preparation of the codification and one for the collection of the sources of Eastern law, in which experts of all rites were involved. These collections were published in three series, begun respectively in 1930, 1935, and 1942.

In 1935 the preparatory commission became the Pontifical Commission for the Redaction of the *Codex Juris Canonici Orientalis* ("Code of Oriental Canon Law"). The cooperation of all Eastern ordinaries (bishops, patriarchs, and others having jurisdictions) was requested, and the drafts of the various documents were sent to them. Thereafter four parts were published: in 1949, on marriage law; in 1952, on the law for monks and other religious, on ecclesiastical properties, and a title *De Verborum Significatione* ("Concerning the Meaning of Words"), a series of definitions of legal terms used in the canons; and in 1957, on constitutional law, especially of the clergy. The still incomplete codification followed the Latin code with the assimilation of the authentic interpretation and with textual corrections, and also with the insertion of the general law proper to the Eastern churches, including the Orthodox churches, regarding the patriarchs and their synods, marriage law, the law of religious, and other matters. The promulgation was made only in Latin in the *Acta Apostolicae Sedis,* the official organ of the Holy See. The Catholic Eastern churches came under the Congregation for the Eastern Churches that was established on Jan. 6, 1862, by Pius IX as part of the *Propaganda Fide,* and was made independent by Benedict XV on May 1, 1917, and expanded considerably by Pius XI on March 25, 1938. Roman legislation as well as the jurisdiction of a congregation of the Roman Curia was criticized as being incompatible with the traditional autonomy of the Eastern churches in legislation and administration.

THE SECOND VATICAN COUNCIL AND POST-CONCILIAR CANON LAW

Vatican II. Fundamental to the development of canon law in the Roman Catholic Church is the second Vatican Council's (Oct. 11, 1962–Dec. 8, 1965) vision of the church as the people of God. In this connection the former concept of the church as *societas perfecta* (the "perfect society"), founded by Christ through the mission of the Apostles and their successors, to which one belongs through subjection to the hierarchy, is replaced by a vision of the church as a community in which all possess the sacramental mission to live and proclaim the Gospel, and all have a function in the service of the whole. The legislative and administrative functions remain related to the hierarchy, but this is much more expressly seen as a service for the religious life of the community. The idea of collegiality, resting on the recognition of the vocation received by each one from the Lord, works itself out in the relationship existing among the bishops and with the pope, of the bishops with the clergy, and of the clergy with the laity. Related to this is a tendency to co-responsibility and the democratization of the church structure and also an autonomy for the laity to exercise individually and collectively the Christian mission proper to them; namely, to bring the spirit of Christ into the secular life of mankind. The right of clergy and laity to a share in the leadership of bishops and pope is recognized. The vision of the people of God as *sacramentum mundi,* a sign of redemption for all mankind, gave a new insight into the relationships with the Protestant churches, the other world religions, and the nonreligious atheistic and humanistic movements. In this view, freedom of religion and philosophy became the most fundamental right of humanity.

The church and collegiality

Post-conciliar legislation. From a schematically chronological survey of the principal conciliar and post-conciliar legislation a new era apparently began for canon law. In 1960, the Secretariat for Promoting Christian Unity was established. Three years later various faculties, previously reserved to Rome, were given to the bishops; and in 1964, actions were undertaken for the reorganization of the papal commission for communications media, establishment of the Secretariat for Non-Christians, and lifting of the prohibition against cremation. Other legislative changes indicating a new era included several regulations that could not have been proposed with any possibility of their being accepted prior to Vatican II. In 1965, for example, preeminence in the College of Cardinals was given to Eastern patriarchs, after deacon and subdeacon and after the cardinals of the dioceses of the province of Rome; in the same year the Secretariat for Non-Believers

Canon law after 1960

was established and the Holy Office (formerly the Inquisition) became the Congregation for the Doctrine of the Faith, with emphasis on the positive fostering of theological research. In 1966, greatly reduced prescriptions for fasting and abstinence were adopted, the Index of prohibited books became a moral guide instead of obligatory law, and in implementation of the conciliar degree on the episcopal office, the principle according to which ordinaries (*e.g.*, bishops) dispense from universal laws only when this is allowed by law or special faculties was replaced by the principle that ordinaries can always dispense unless it is explicitly reserved to Rome—and such reserved dispensations in question are indicated.

In addition to these changes, further canonical regulations were accepted. New regulations for mixed marriages were adopted in 1966. Norms were established for the implementation of the conciliar decrees on the office of bishops and priests; missionary activity; personal and material aid to needy churches; introduction of priests' councils and pastoral councils of priests, religious (*i.e.*, monks and nuns), and laity as advisory groups for bishops; international episcopal conferences and their mutual relationships; and other concerns. From 1967 to 1970 more changes were made in canonical regulations—*e.g.*, in 1967, total revision of the norms for indulgences, establishment in the Roman Curia of the council of laymen and the study commission Justitia et Pax ("Justice and Peace"), new dispensation rights for Eastern bishops, directory for ecumenical cooperation with Christian churches, regulation of the office of the diaconate to include married men, and reorganization of the Roman Curia; in 1970, a mandate to the secretary of state to discuss with the world episcopacy the question of celibacy and ordination of married men in areas that need priests.

Characteristics of the new regulations included a searching for structures to allow all members of the church to have a voice in ecclesiastical decision making and decentralization and autonomy of local churches. Regulations from Rome were kept to the general, with ample room for local adaptation. In addition, new regulations were to be enacted only after extensive and open inquiry and test by experience, with possibilities for experimentation. In place of regulations of religious behaviour, canon law was becoming an ordering of the cooperation of all members of the Roman Catholic Church for the realization of its mission in the world.

Revision of the Code of Canon Law. On Jan. 25, 1959, John XXIII announced the revision of the church's code. On March 28, 1963, he set up a commission of cardinals for that purpose. On April 17, 1964, Paul VI named the first consultants. No publicity was given to the commission's work, but the first episcopal synod (Sept. 30–Oct. 4, 1967) gave its approval to a document in which several principles for the revision were indicated (*Principia quae codicis juris canonici recognitionem dirigant,* or "Principles Which Guide the Recognition of the Code of Canon Law"): the juridical character of the code ought to be preserved and not, as some wished, be limited to a rule for faith and morals; canon law for the area of each one's personal conscience should be maintained, but conflicts between law for conscience and public law ought to be avoided, especially in marriage and penal law; as a means to stimulate pastoral work it was recommended that the laws be expressed in a spirit of love, fairness, and humanity; no binding prescriptions were to be given where admonition and counsel suffice; pastoral workers were to be given more discretionary powers, and greater freedom was to be given to bishops, especially in mission areas; laws were to be such that ample possibility is given for local adaptation, carrying through the principle of subsidiarity (*i.e.*, that nothing should be committed to higher organs that can be accomplished by individuals or lesser or subordinate bodies), however, with care to retain the unity of law and jurisdiction; regulation of administrative jurisdiction and in principle public jurisdiction; distinction of legislative, administrative, and judicial functions; limitation of punishments, in particular limitation of punishments incurred automatically upon commission of the offense to very few and very serious crimes. On May 28, 1968, the commission approved a preliminary division of the new codex. (P.Hu./Ed.)

Principles for revision of the code

As the drafts of the various parts of the new code became available, a vast process of consultation was initiated. The departments of the Roman Curia, the local bishops and their regional conferences, the heads of religious institutes, and university faculties of canon law were invited to evaluate the schemata and offer suggestions for their improvement. This lengthy procedure was completed in 1982.

The new Code of Canon Law. The second *Codex Juris Canonici* in history for the Catholics of the Latin rite was promulgated by Pope John Paul II on Jan. 25, 1983, and entered into effect on Nov. 27, 1983. It contains 1,752 canons divided among seven books. The books are: (1) "General Norms," concerning the operating principles of canon law, definitions of juridical persons, and ecclesiastical offices; (2) "The People of God," describing the rights and duties of the faithful in general and of clerics and lay persons in particular, as well as the organizational structures of the church, papacy, episcopal college, Roman Curia, particular churches, and institutes of consecrated life; (3) "The Teaching Office of the Church," concerning catechetical and missionary activities, schools, and media of communication; (4) "The Sanctifying Office of the Church," describing sacraments and worship in all its forms; (5) "The Temporal Goods of the Church," defining ownership and administration of property, contracts, and charitable foundations; (6) "Sanctions in the Church," describing various crimes, delicts, and penalties; and (7) "Procedures," outlining the administration of justice by ecclesiastical courts, various quasi-judicial actions, and remedies.

The declared intention of the drafters of the new code was to give practical effect to the theological insights of the second Vatican Council. The emphasis in the new law is on the universal people of God, and the governing power of the hierarchy is presented as a call to serve. The fundamental rights of the faithful are clearly asserted, and their active participation in the life of the church is encouraged. An effort was made toward decentralization, with local bishops enjoying more autonomy. Despite criticism from some scholars and clerics that the new code remains conservative on certain issues, it is recognized that the body of the law is permeated by an ecumenical spirit and displays a respect for the freedom of conscience and religious conviction of every human being. With the new code the hermeneutics of canon law have changed significantly. Apart from the strictly legal transactions, creating enforceable rights and duties (as in matters of property), the application of the laws must be guided and moderated according to pastoral needs.

The Eastern churches. A process similar to that used for the preparation of the new code for the Latin church was in progress during the 1980s for all the Eastern Catholic churches. The first draft of the new, unified code of laws was completed in 1986. It consists of 1,561 canons, organized into 30 titles. The institutions and structures of the Uniate churches are supported; the right to worship according to their own liturgical traditions is confirmed. The dignity and power of the patriarchs and of the major archbishops are recognized; the importance of synodal government at different levels is affirmed. Overall, the major themes found in this draft are the same as the ones in the Latin code (although arranged in a different order); in matters of common interest many canons are taken word-by-word from the Latin code. The process of consultation over this schema, once completed, is likely to bring about many changes in the proposed canons. The task of codifying in a single volume the laws of so many churches—having different historical memories, rooted in various cultures, and without a common language—is a daunting one, even if they all profess the same faith and are in communion with Rome. (L.M.Ö.)

The proposed Oriental Code

ANGLICAN CANON LAW

The Anglican Communion embraces the Church of England and its affiliated churches. Since the submission of the clergy demanded by King Henry VIII and the Act of Supremacy in 1534, in which the Parliament recognized

him as supreme head of the Church of England and which was renewed by Queen Elizabeth I, the law of the English Church rests on the supremacy of the prince or of the Parliament. It is theoretically accepted that, outside the law determined by the English synods in the ancient independent national churches, only the principles of the *jus ecclesiasticum commune* ("common ecclesiastical law") are binding, but other norms, promulgated by popes and councils, are accepted only to the extent that they were accepted by English ecclesiastical or secular courts. For practical purposes the development of church law in the English Church is held by some canonists (usually Roman Catholic) to be not canon law but the ecclesiastical law of the state. The hierarchy has the power to ordain by virtue of the apostolic succession, which was preserved—according to the Anglican view—by the consecration of Matthew Parker as archbishop of Canterbury (1559), but it does not possess legislative authority. The ecclesiastical provinces are administered by convocations of Canterbury and York, consisting of an upper house of bishops and a lower house of clergy. In 1919 a Church Assembly was established by the Enabling Act; the assembly consists of three houses (of bishops, members of the convocations, and laity) with the authority to make proposals relating to any matter concerning the Church of England—with the exception of dogmas of faith—and to present these proposals to the ecclesiastical committee of Parliament. If the committee agrees on a positive report, then the Parliament can approve or reject the proposal but not amend it; if both houses of Parliament accept it, then it acquires the force of law by royal approval. Lambeth Conferences, which have been held approximately every 10 years since 1867 at the London palace of the archbishop of Canterbury and which involve all Anglican bishops from throughout the world, do not have legislative authority.

Ecclesiastical law of the state

(P.Hu./Ed.)

ASPECTS OF THE CHRISTIAN RELIGION

Patristic literature

Patristic literature is generally identified today with the entire Christian literature of the early Christian centuries, irrespective of its orthodoxy or the reverse. Taken literally, however, patristic literature should denote the literature emanating from the Fathers of the Christian Church, the Fathers being those respected bishops and other teachers of exemplary life who witnessed to and expounded the orthodox faith in the early centuries. This would be in line with the ancient practice of designating as "the Fathers" prominent church teachers of past generations who had taken part in ecumenical councils or whose writings were appealed to as authoritative. Almost everywhere, however, this restrictive definition has been abandoned. There are several reasons why a more elastic usage is to be welcomed. One is that some of the most exciting Christian authors, such as Origen, were of questionable orthodoxy, and others—Tertullian, for example—deliberately left the church. Another is that the undoubtedly orthodox Fathers themselves cannot be properly understood in isolation from their doctrinally unorthodox contemporaries. Most decisive is the consideration that early Christian literature exists, and deserves to be studied, as a whole and that much will be lost if any sector is neglected because of supposed doctrinal shortcomings.

Reasons for a broad concept of patristic literature

THE ANTE-NICENE PERIOD

During the first three centuries of its existence the Christian Church had first to emerge from the Jewish environment that had cradled it and then come to terms with the predominantly Hellenistic (Greek) culture surrounding it. Its legal position at best precarious, it was exposed to outbursts of persecution at the very time when it was working out its distinctive system of beliefs, defining its position vis-à-vis Judaism on the one hand and Gnosticism (a heretical movement that upheld the dualistic view that matter is evil and the spirit good) on the other, and constructing its characteristic organization and ethic. It was a period of flux and experiment, but also one of consolidation and growing self-confidence, and these are all mirrored in its literature.

Earliest patristic writings

The Apostolic Fathers. According to conventional reckoning, the earliest examples of patristic literature are the writings of the so-called Apostolic Fathers; the name derives from their supposed contacts with the Apostles or the apostolic community. These writings include the church order called the *Didachē*, or *Teaching of the Twelve Apostles* (dealing with church practices and morals), the *Letter of Barnabas,* and the *Shepherd of Hermas,* all of which hovered at times on the fringe of the New Testament canon in that they were used as sacred scripture by some local churches; the *First Letter of Clement,* the seven letters that Ignatius of Antioch (d. *c.* 110) wrote when being escorted to Rome for his martyrdom, the related *Letter to the Philippians* by Polycarp of Smyrna (d. *c.* 156 or 168), and the narrative report of Polycarp's martyrdom; some fragmentary accounts of the origins of the Gospels by Papias (fl. late 1st or early 2nd century AD), bishop of Hierapolis in Phrygia, Asia Minor; and an ancient homily (sermon) known as the *Second Letter of Clement.* They all belong to the late 1st or early 2nd century and were all to a greater or lesser extent influenced (sometimes by way of reaction) by the profoundly Jewish atmosphere that pervaded Christian thinking and practice at this primitive stage. For this reason alone, modern scholars tend to regard them as a somewhat arbitrarily selected group. A more scientific assessment would place them in the context of a much wider contemporary Jewish-Christian literature that has largely disappeared but whose character can be judged from pseudepigraphal (or noncanonical) works such as the *Ascension of Isaiah,* the *Odes of Solomon,* and certain extracanonical texts modeled on the New Testament.

Even with this qualification the Apostolic Fathers, with their rich variety of provenance and genre (types), illustrate the difficult doctrinal and organizational problems with which the church grappled in those transitional generations. Important among these problems were the creation of a ministerial hierarchy and of an accepted structure of ecclesiastical authority. The *Didachē,* which is Syrian in background and possibly the oldest of these documents, suggests a phase when Apostles and prophets were still active but when the routine ministry of bishops and deacons was already winning recognition. The *First Letter of Clement,* an official letter from the Roman to the Corinthian Church, reflects the more advanced state of a collegiate episcopate, with its shared authority among an assembly of bishops. This view of authority was supported by an emergent theory of apostolic succession in which bishops were regarded as jurisdictional heirs of the early Apostles. The *First Letter of Clement* is also instructive in showing that the Roman Church, even in the late 1st century, was asserting its right to intervene in the affairs of other churches. The letters of Ignatius, bishop of Antioch at the beginning of the 2nd century, depict the position of the monarchical bishop, flanked by subordinate presbyters (priests) and deacons (personal assistants to the bishop), which had been securely established in Asia Minor.

Almost more urgent was the question of the relation of Christianity to Judaism, and in particular of the Christian attitude toward the Old Testament. In the *Didachē* there is little sign of embarrassment; Jewish ethical material is taken over with suitable adaptations, and the Jewish basis of the liturgical elements is palpable. But with *Barnabas* the tension becomes acute; violently anti-Jewish, the Alexandrian author substitutes allegorism (use of symbolism) for Jewish literalism and thus enables himself to wrest a Christian meaning from the Old Testament. The same tension is underlined by Ignatius' polemic against Judaizing tendencies in the church. At the same time all these writings—especially those of Ignatius, Polycarp, and Papias—testify to the growing awareness of a specifically

Relationship of Judaism and Christianity

Christian tradition embodied in the teaching transmitted from the Apostles.

Almost all the Apostolic Fathers throw light on primitive doctrine and practice. The *Didachē,* for example, presents the Eucharist as a sacrifice, and *I Clement* incorporates contemporary prayers. *II Clement* invites its readers to think of Christ as of God, and of the church as a preexistent reality. The *Shepherd of Hermas* seeks to modify the rigorist view that sin committed after baptism cannot be forgiven. But the real key to the theology of the Apostolic Fathers, which also explains its often curious imagery, is that it is Jewish-Christian through and through, expressing itself in categories derived from latter-day Judaism and apocalyptic literature (depicting the intervention of God in history in the last times), which were soon to become unfashionable and be discarded.

The Gnostic writers. Hardly had the church thrown off its early Jewish-Christian idiosyncrasies when it found itself confronted by the amorphous but pervasive philosophical-religious movement known as Gnosticism. This movement made a strong bid to absorb Christianity in the 2nd century, and a number of Christian Gnostic sects flourished and contributed richly to Christian literature. Although the church eventually maintained its identity intact, the confrontation forced it to clarify its ideas on vital issues on which it differed sharply from the Gnostics. Chief among these were the Gnostics' distinction between the unknown supreme God and the Demiurge (identified with the God of the Old Testament) who created this world; their dualist disparagement of the material order and insistence that the Redeemer became incarnate in appearance only; their belief in salvation by esoteric knowledge; and their division of humanity into a spiritual elite able to achieve salvation and, below this elite, "psychics" capable of a modified form of salvation and "material" people cut off from salvation.

Gnostic emphasis

Among the leading 2nd-century Christian Gnostics were Saturninus and Basilides, reputedly pupils of Menander, a disciple of Simon Magus (late 1st century), the alleged founder of the movement; they worked at both Antioch and Alexandria. Most famous and influential was the Egyptian Valentinus, who acquired a great reputation at Rome (*c.* 150) and founded an influential school of thought. Basilides and Valentinus are reported to have written extensively, and their systems can be reconstructed from hostile accounts by Irenaeus, Clement of Alexandria, and other orthodox critics. The Gnostics generally seem to have been prolific writers, and as they needed their own distinctive scriptures they soon created a body of apocryphal books patterned on the New Testament. It was a Syrian Gnostic convert, Tatian, who compiled (late 2nd century) the first harmony of the four Gospels (the *Diatessaron*)—a single gospel using the material from the Gospels; and an Italian Gnostic, Heracleon (2nd century), who prepared the earliest commentary on the Gospel According to John (extracts from it were preserved by Origen). Epiphanius (*c.* 315–403) preserved a *Letter to Flora,* by the Valentinian Gnostic Ptolemaeus (late 2nd century), supplying rules for interpreting the Mosaic Law (the Torah) in a Christian sense; and another disciple of Valentinus, Theodotus (2nd century), published an account of his master's system that was excerpted by Clement of Alexandria.

Almost the entire vast literature of Gnosticism has perished, and until recently the only original documents available to scholars (apart from extracts such as those already mentioned, which were preserved by orthodox critics) were a handful of treatises in Coptic contained in three codices (manuscript books) that were discovered in the 18th and late 19th centuries. The most interesting of these are *Pistis Sophia* and the *Apocryphon of John,* the former consisting of conversations of the risen Jesus with his disciples about the fall and redemption of the aeon (emanation from the Godhead) called Pistis Sophia, the latter of revelations made by Jesus to St. John explaining the presence of evil in the cosmos and showing how mankind can be rescued from it.

The Naj' Ḥammādī codices

Since 1945, however, this meagre store has been richly supplemented by the discovery near Naj' Ḥammādī, in Egypt on the Nile about 78 miles northwest of Luxor, of 13 codices containing Christian Gnostic treatises in Coptic translations. Among these, the Jung Codex (named in honour of the psychoanalyst Carl Jung by those who purchased it for his library) includes five important items: a *Prayer of the Apostle Paul;* an *Apocryphon of James,* recording revelations imparted by the risen Christ to the Apostles; the *Gospel of Truth,* perhaps to be identified with the work of this name attributed by Irenaeus to Valentinus; the *Epistle to Rheginos,* a Valentinian work, possibly by Valentinus himself, on the Resurrection; and a *Tripartite Treatise,* probably written by Heracleon, of the school of Valentinianism. The other documents from the Naj' Ḥammādī library include the *Gospel of Thomas,* a collection of sayings and parables that are ascribed to Jesus; the *Apocryphon of John,* which represents the first chapter of Genesis in mythological terms; and writings ascribed to Philip, Mary Magdalene, Adam, Peter, and Paul.

A figure of immense significance who is often, though perhaps mistakenly, counted among the Gnostics was Marcion, who after breaking with the Roman Church in 144 set up a successful organization of his own. Teaching that there is a radical opposition between the Law and the Gospel, he refused to identify the God of love revealed in the New Testament with the wrathful Creator God of the Old Testament. He set forth these contrasts in his *Antitheses,* and his adoption of a reduced New Testament consisting of the Gospel According to Luke and certain Pauline epistles, all purged of presumed Jewish interpolations, had an important bearing on the church's formation of its own fuller canon.

The Apologists. The orthodox literature of the 2nd and early 3rd centuries tends to have a distinctly defensive or polemical colouring. It was the age of Apologists, and these Apologists engaged in battle on two fronts. First, there was the hostility and criticism of pagan society. Because of its very aloofness the church was popularly suspected of sheltering all sorts of immoralities and thus of threatening the established order. At a higher level, Christianity, as it became better known, was being increasingly exposed to intellectual attack. The physician Galen of Pergamum (129–*c.* 199) and the Middle Platonist thinker Celsus, who followed the religiously inclined form of Platonism that flourished from the 3rd century BC to the 3rd century AD (compare his devastating *Alēthēs logos,* or *True Word,* written *c.* 178), were only two among many "cultured despisers." But, second, orthodoxy had to take issue with distorting tendencies within, whether these took the form of Gnosticism or of other heresies, such as the so-called semi-Gnostic Marcion's rejection of the Old Testament revelation or the claim of the ecstatic prophet from Phrygia, Montanus, to be the vehicle of a new outpouring of the Holy Spirit. Christianity had also to define exactly where it stood in relation to Hellenistic culture.

Characteristics of apologetic literature

Strictly speaking, the term Apologists denotes the 2nd-century writers who defended Christianity against external critics, pagan and Jewish. The earliest of this group was Quadratus, who in about 124 addressed an apology for the faith to the emperor Hadrian; apart from a single fragment it is now lost. Other early Apologists who are mere names known to scholars are Aristo of Pella, the first to prepare an apology to counter Jewish objections, and Apollinaris, bishop of Hierapolis, said to be the author of numerous apologetic works and also of a critique of Montanism. An early apology that has survived intact is that of Aristides, addressed about 140 to the emperor Antoninus Pius; after being completely lost, the text was rediscovered in the 19th century. The most famous Apologist, however, was Justin, who was converted to Christianity after trying various philosophical schools, paid lengthy visits to Rome, and was martyred there (*c.* 165). Justin's two *Apologies* are skillful presentations of the Christian case to the pagan critics; and his *Dialogue with Trypho* is an elaborate defense of Christianity against Judaism.

Relationship to philosophy

Justin's attitude to pagan philosophy was positive, but his pupil Tatian could see nothing but evil in the Greco-Roman civilization. Indeed, Tatian's *Discourse to the Greeks* is less a positive vindication of Christianity than a sharp attack on paganism. His contemporary Athenagoras of Athens, author of the apologetic work *Embassy for*

the Christians and a treatise *On the Resurrection of the Dead,* is as friendly as Justin to Greek culture and philosophy. Two others who deserve mention are Theophilus of Antioch, a prolific publicist whose only surviving work is *To Autolycus,* prepared for his pagan friend Autolycus; and the anonymous author of the *Letter to Diognetus,* an attractive and persuasive exposition of the Christian way of life that is often included among the Apostolic Fathers.

As stylists the Apologists reach only a passable level; even Athenagoras scarcely achieves the elegance at which he obviously aimed. But they had little difficulty in refuting the spurious charges popularly brought against Christians, including atheism, cannibalism, and promiscuity, or in mounting a counterattack against the debasements of paganism. More positively, they strove to vindicate the Christian understanding of God and specific doctrines such as the divinity of Christ and the resurrection of the body. In so doing, most of them exploited current philosophical conceptions, in particular that of the Logos (Word), or rational principle underlying and permeating reality, which they regarded as the divine reason, become incarnate in Jesus. They have been accused of Hellenizing Christianity (making it Greek in form and method), but they were in fact attempting to formulate it in intellectual categories congenial to their age. In a real sense they were the first Christian theologians. But the same tension between the Gospel and philosophy was to persist throughout the patristic period, with results that were sometimes positive, as in Augustine and Gregory of Nyssa, and sometimes negative, as in the radical Arians Aëtius and Eunomius.

As the 2nd century advanced, a more confident, aggressive spirit came over Christian Apologists, and their intellectual and literary stature increased greatly. Clement of Alexandria, for example, while insisting on the supremacy of faith, freely drew on Platonism and Stoicism to clarify Christian teaching. In his *Protreptikos* ("Exhortation") and *Paidagōgos* ("Instructor") he urged pagans to abandon their futile beliefs, accept the Logos as guide, and allow their souls to be trained by him. In interpreting scripture he used an allegorizing method derived from the Jewish philosopher Philo, and against Gnosticism he argued that the baptized believer who studies the Scriptures is the true Gnostic, faith being at once superior to knowledge and the beginning of knowledge.

The critique of Gnosticism was much more systematically developed by Clement's older contemporary, Irenaeus of Lyon, in his voluminous *Against Heresies.* While countering the Valentinian dualism that asserted that spirit was good and matter evil, this treatise makes clear the church's growing reliance on its creed or "rule of faith," on the New Testament canon, and on the succession of bishops as guarantors of the true apostolic tradition. Irenaeus was also a constructive theologian, expounding ideas about God as Creator, about the Son and the Spirit as his "two hands," about Christ as the New Adam who reconciles fallen humanity with God, and about the worldwide church with its apostolic faith and ministry, a concept that theology was later to take up eagerly.

More brilliant as a stylist and controversialist, the North African lawyer Tertullian was also the first Latin theologian of considerable importance. Unlike Clement, he reacted with hostility to pagan culture, scornfully asking, "What has Athens to do with Jerusalem?" His *Apology* remains a classic of ancient Christian literature, and his numerous moral and practical works reveal an uncompromisingly rigid moral view. Although later becoming a Montanist himself (a follower of the morally rigorous and prophetic sect founded by Montanus), he wrote several antiheretical tracts, full of abuse and biting sarcasm. Yet, in castigating heresy he was able to formulate the terminology, and to some extent the theory, of later Trinitarian and Christological orthodoxy; his teaching on the Fall of Man, aimed against Gnostic dualism, in part anticipates Augustine.

Roughly contemporary with Tertullian, and like him an intellectual and a rigorist, was Hippolytus, a Greek-speaking Roman theologian and antipope. He, too, had a vast literary output, and although some of the surviving works attributed to him are disputed, it is probable that he wrote the comprehensive *Refutation of All Heresies,* attacking Gnosticism, as well as treatises denouncing specifically Christian heresies. He was also the author both of numerous commentaries on scripture and (probably) of the *Apostolic Tradition,* an invaluable source of knowledge about the primitive Roman liturgy. His *Commentary on Daniel* (*c.* 204) is the oldest Christian biblical commentary to survive in its entirety. His exegesis (interpretive method) is primarily typological—*i.e.,* treating the Old Testament figures, events, and other aspects as "types" of the new order that was inaugurated by Christ.

Late 2nd to early 4th century. Meanwhile, a brilliant and distinctive phase of Christian literature was opening at Alexandria, the chief cultural centre of the empire and the meeting ground of the best in Hellenistic Judaism, Gnosticism, and Neoplatonism. Marked by the desire to present Christianity in intellectually satisfying terms, this literature has usually been connected with the catechetical school, which, according to tradition, flourished at Alexandria from the end of the 2nd through the 4th century. Except for the brief period, however, when Origen was in charge of it, it may be doubted whether the school was ever itself a focus of higher Christian studies. When speaking of the school of Alexandria, some scholars claim that it is better to think of a distinguished succession of like-minded thinkers and teachers who worked there and whose highly sophisticated interpretation of Christianity exercised for generations a formative impact on large sectors of eastern Christendom.

The catechetical school of Alexandria

The real founder of this theology, with its Platonist leaning, its readiness to exploit the metaphysical implications of revelation, and its allegorical understanding of scripture, was Clement (*c.* 150–*c.* 215), the Christian humanist whose welcoming attitude to Hellenism and critique of Gnosticism were noted above. His major work, the *Strōmateis* ("Miscellanies"), untidy and deliberately unsystematic, brings together the inheritance of Jewish Christianity and Middle Platonism in what aspires to be a summary of Christian gnosis (knowledge). All his reasoning is dominated by the idea of the Logos who created the universe and who manifests the ineffable Father alike in the Old Testament Law, the philosophy of the Greeks, and finally the incarnation of Christ. Clement was also a mystic for whom the higher life of the soul is a continuous moral and spiritual ascent.

Significance and influence of Origen

But it is Origen (*c.* 185–*c.* 254) whose achievement stamps the Alexandrian school. First and foremost, he was an exegete (critical interpreter), as determined to establish the text of scripture scientifically (compare his *Hexapla*) as to wrest its spiritual import from it. In homilies, scholia (annotated works), and continuous commentaries he covered the whole Bible, deploying a subtle, strongly allegorical exegesis designed to bring out several levels of significance. As an apologist, in his *Contra Celsum,* he refuted the pagan philosopher Celsus' damaging onslaught on Christianity. In all his writings, but especially his *On First Principles,* Origen shows himself to be one of the most original and profound of speculative theologians. Neoplatonist in background, his system embraces both the notion of the preexistence of souls, with their fall and final restoration, and a deeply subordinationist doctrine of the Trinity—*i.e.,* one in which the Son is subordinate to the Father. For his spiritual teaching, with its emphasis on the battle against sin, on freedom from passions, and on the soul's mystical marriage with the Logos, his *Commentary on Canticles* provides an attractive introduction.

Origen's influence on Christian doctrine and spirituality was to be immense and many-sided; the orthodox Fathers and the leading heretics of the 4th century alike reflect it. Meanwhile, the Alexandrian tradition was maintained by several remarkable disciples. Two of these whose works have been entirely lost but who are reported to have been polished writers were Theognostus (fl. 250–280) and Pierius (fl. 280–300), both heads of the catechetical school and apparently propagators of Origen's ideas. But there are two others of note, Dionysius of Alexandria (*c.* 200–*c.* 265) and Gregory Thaumaturgus (*c.* 213–*c.* 270), of whose works some fragments have survived. Dionysius of Alexandria wrote on natural philosophy and the Christian doctrine of creation but is chiefly remembered for his dis-

pute with Pope Dionysius (reigned 259–268) of Rome on the correct understanding of the Trinity. In this Dionysius of Alexandria is revealed as a faithful exponent of Origen's pluralism and subordinationism. Gregory Thaumaturgus left a fascinating *Panegyric to Origen,* giving a graphic description of Origen's method of instruction, as well as a dogmatically important *Symbol* and a *Canonical Epistle* that is in effect one of the most ancient treatises of casuistry (*i.e.,* the application of moral principles to practical questions).

If Origen inspired admiration, his daring speculations also provoked criticism. At Alexandria itself, Peter, who became bishop in about 300 and composed theological essays of which only fragments remain, attacked Origen's doctrines of the preexistence of souls and their return into the condition of pure spirits. But the acutest of his critics was Methodius of Olympus (d. 311), of whose treatises *The Banquet,* exalting virginity, survives in Greek and others mainly in Slavonic translations. Although indebted to Alexandrian allegorism, Methodius remained faithful to the Asiatic tradition (literal and historical) of Irenaeus—who had come to France from Asia Minor—and his realism and castigated Origen's ideas on the preexistence of souls, the flesh as the spirit's prison, and the spiritual nature of the resurrected body. As a writer he strove after literary effect, and Jerome, writing a century later, praised the excellence of his style.

Origin and gradual emergence of Latin patristic literature

Latin Christian literature was slow in getting started, and North Africa has often been claimed as its birthplace. Tertullian, admittedly, was the first Christian Latinist of genius, but he evidently had humbler predecessors. Latin versions of the Bible, recoverable in part from manuscripts, were appearing in Africa, Gaul, and Italy during the 2nd century. In that century, too, admired works such as *I Clement, Barnabas,* and the *Shepherd of Hermas* were translated into Latin. The oldest original Latin texts are probably the Muratorian Canon, a late 2nd-century Roman canon, or list of works accepted as scripture, and the *Acts of the Scillitan Martyrs* (180) of Africa.

The first noteworthy Roman Christian to use Latin was Novatian, the leader of a rigorist schismatic group. His surviving works reveal him as an elegant stylist, trained in rhetoric and philosophy, and a competent theologian. His doctrinally influential *De trinitate* ("Concerning the Trinity") is basically apologetic: against Gnostics it defends the oneness and creative role of Almighty God, against Marcion it argues that Christ is the Son of God the Creator, against Docetism (the heresy claiming that Jesus only seemed the Christ) that Christ is truly man, and against Sabellianism (the denial of real distinctions in the Godhead, viewing the Father, Son, and Holy Spirit as three successive modes of revelation) that in spite of Christ's being fully divine there is but one God. His rigorous moralism comes out in his *On Public Shows* and *On the Excellence of Chastity* (both once attributed to Cyprian); in *On Jewish Foods* he maintains that the Old Testament food laws no longer apply to Christians, the animals that were classified as unclean having been intended to symbolize vices.

Works of Cyprian

A much greater writer than Novatian was his contemporary and correspondent, Cyprian, the statesmanlike bishop of Carthage. A highly educated convert to Christianity, Cyprian left a large corpus of writings, including 65 letters and a number of moral, practical, and theological treatises. As an admirer of Tertullian, he continued some of his fellow North African's tendencies, but his style is more classical, though much less brilliant and individual. Cyprian's letters are a mine of information about a fascinating juncture in church history. His collections of *Three Books of Testimonies to Quirinus,* or authoritative scripture texts, illustrate the church's reliance on these in defending its theological and ethical positions. A work that has been of exceptional importance historically is *On the Unity of the Catholic Church,* in which Cyprian contends that there is no salvation outside the church and defines the role of the Roman see. His *To Demetrianus* is an original, powerful essay refuting the allegation of pagans that Christianity was responsible for the calamities afflicting society.

Three writers from the later portion of this period deserve mention. Victorinus of Pettau was the first known Latin biblical exegete; of his numerous commentaries the only one that remains is the commentary on Revelation, which maintained a millenarian outlook—predicting the 1,000-year reign of Christ at the end of history—and was clumsy in style. Arnobius the Elder (converted by 300) sought in his *Adversus nationes* ("Against the Pagans"), like Tertullian and Cyprian before him, to free Christianity from the charge of having caused all the evils plaguing the empire, but ended up by launching a violent attack on the contemporary pagan cults. A surprising feature of this ill-constructed, verbose apology is Arnobius' apparent ignorance concerning several cardinal points of Christian doctrine, combined with his great enthusiasm for his newfound faith.

By contrast, his much abler pupil Lactantius (*c.* AD 240–*c.* 320), like him a native of North Africa, was a polished writer and the leading Latin rhetorician of the day. His most ambitious work, the *Divine Institutes,* attempted, against increasingly formidable pagan attacks, to portray Christianity as the true form of religion and life and is in effect the first systematic presentation of Christian teaching in Latin. The later *On the Death of Persecutors,* now generally recognized as his, describes the grim fates of persecuting emperors; it is a primary source for the history of the early 4th century and also represents a crude attempt at a Christian philosophy of history.

THE POST-NICENE PERIOD

The 4th and early 5th centuries witnessed an extraordinary flowering of Christian literature, the result partly of the freedom and privileged status now enjoyed by the church, partly of the diversification of its own inner life (compare the rise of monasticism), but chiefly of the controversies in which it hammered out its fundamental doctrines.

Arianism, which denied Christ's essential divinity, aroused an all-pervasive reaction in the 4th century; the task of the first two ecumenical councils, at Nicaea (325) and Constantinople (381), was to affirm the orthodox doctrine of the Trinity. In the 5th century the Christological question moved to the fore, and the Council of Chalcedon (451), completing that of Ephesus (431), defined Christ as one person in two natures. The Christological controversies of the 5th century were extremely complex, involving not only theological issues but also issues of national concerns—especially in the Syrian-influenced East, where the national churches were called non-Chalcedonian because they rejected the doctrinal formulas of the Council of Chalcedon.

Involved in the 5th-century Christological controversy were many persons and movements: Nestorius, consecrated patriarch of Constantinople in 428, and his followers, the Nestorians, who were concerned with preserving the humanity of Christ as well as his divinity; Cyril, patriarch of Alexandria, and his followers, who were devoted to maintaining a balanced emphasis on both of the natures of Christ, divine and human; Eutyches (*c.* 378–after 451), a muddleheaded archimandrite (head of a monastery) who affirmed two natures before and one nature after the incarnation; the Monophysites, who (following Eutyches) stressed the one unified nature of Christ; and the moderates and those who sought theological, ecclesiastical, and even political solutions to this highly complex doctrinal dispute, such as Pope Leo I. It was a time when the Alexandrian and Antiochene theological schools vied with each other for the control of the theology of the church. In the Syrian East the Antiochene tradition continued in the schools of Edessa and Nisibis, which became centres of a non-Greek national renaissance. The issues of grace, free will, and the Fall of Man concerned the West mainly. Meanwhile, old literary forms were developing along more mature lines, and new ones were emerging, including historiography, lives of saints, set piece (fixed-form) oratory, mystical writings, and hymnody.

Literature of the Arian controversy

The Nicene Fathers. A seesaw struggle between Arians and orthodox Christians dominated the immediate post-Nicene period. Arius himself, Eusebius of Nicomedia, and other radicals occupied the extreme left wing, carrying Origen's views on the subordination of the Son to what

became dangerous lengths. Apart from a few precious letters and fragments, their writings have perished. On the extreme right Athanasius, Eustathius of Antioch, and Marcellus of Ancyra (strongly anti-Origenist) tenaciously upheld the Nicene decision that the Son was of the same substance with the Father. Again, the writings of the two latter figures, except for scattered but illuminating fragments, have disappeared. Most churchmen preferred the middle ground; loyal to the Origenist tradition, they suspected the Nicene Creed of opening the door to Sabellianism but were equally shocked by Arianism in its more uncompromising forms. Eusebius of Caesarea (*c.* 260–*c.* 340) was their spokesman, and for decades the eastern emperors supported his mediating line.

Eusebius is chiefly known as a historian; his *Ecclesiastical History,* with its scholarly use of documents and guiding idea that the victory of Christianity is the proof of its divine origin, introduced something novel and epoch-making. But he also wrote voluminous apologetic treatises, biblical and exegetical works, and polemical tracts against Marcellus of Ancyra. From these can be gathered his theology of the Word, which was Origenist in inspiration and profoundly subordinationist and which made the strict Nicenes suspect him as an ally of Arius. Such suspicions were unjust, for he upheld Origen's doctrine of eternal generation (*i.e.,* that the Word is generated outside the category of time) and rejected the extreme Arian theses. His influence can be studied in the works of Cyril of Jerusalem (*c.* 315–386?), whose *Catecheses,* or introductory lectures on Christian doctrine for candidates for baptism, exemplify a pastoral type of Christian literature. Though critical of the Arian positions, Cyril remained reserved in his attitude toward the Nicene theology and at several other points showed affinities with Eusebius.

Significance of Athanasius

Athanasius (*c.* 293–373) bestrides the 4th century as the inflexible champion of the Nicene dogma. He had been present at the council, defending Alexander, the theologian-bishop of Alexandria from 313 to 328, who had exposed Arius; and after succeeding Alexander in 328 he spent the rest of his stormy life defending, expounding, and drawing out the implications of the Nicene theology. His most thorough and effective exposition of the Son's eternal origin in the Father and essential unity with him is contained in his *Four Orations Against the Arians;* but in addition he produced a whole series of treatises, historical or dogmatic or both, as well as letters, covering different aspects of the controversy.

It would be misleading, however, to delineate Athanasius exclusively as a polemicist. First, even in his polemical writings he was working out a positive doctrine of the triune God that anticipated later formal definitions. His *Letters to Bishop Serapion,* with their persuasive presentation of the Holy Spirit as a consubstantial (of the same substance) person in the Godhead, are an admirable illustration. Also his noncontroversial works, such as the relatively early but brilliant apologies *Discourse Against the Pagans* and *The Incarnation of the Word of God;* the attractive and influential *Life of St. Antony,* which was to give a powerful impulse to monasticism (especially in the West); and his numerous exegetical and ascetic essays, which survive largely in fragments, sometimes in Coptic or Syriac translations, should not be overlooked.

The Cappadocian Fathers. Although Athanasius prepared the ground, constructive agreement on the central doctrine of the Trinity was not reached in his lifetime, either between the divided parties in the East or between East and West with their divergent traditions. The decisive contribution to the Trinitarian argument was made by a remarkable group of philosophically minded theologians from Cappadocia—Basil of Caesarea, his younger brother Gregory of Nyssa, and his lifelong friend Gregory of Nazianzus. Of aristocratic birth and consummate culture, all three were drawn to the monastic ideal, and Basil and Gregory of Nazianzus achieved literary distinction of the highest order. While their joint accomplishments in doctrinal definition were indeed outstanding, each made a noteworthy mark in other fields as well.

Contributions to theology and monasticism

So far as Trinitarian dogma is concerned, the Cappadocians succeeded, negatively, in overthrowing Arianism in the radical form in which two acute thinkers, Aëtius (d. *c.* 366) and Eunomius (d. *c.* 394), had revived it in their day, and, positively, in formulating a conception of God as three Persons in one essence that eventually proved generally acceptable. The oldest of Basil's dogmatic writings is his only partially successful *Against Eunomius,* the most mature his essay *On the Holy Spirit.* Gregory of Nyssa continued the attack on Eunomius in four massive treatises and published several more positive dogmatic essays, the most successful of which is the *Great Catechetical Oration,* a systematic theology in miniature. The output of Gregory of Nazianzus was much smaller, but his 45 *Orations,* as well as being masterpieces of eloquence, contain his classic statement of Trinitarian orthodoxy. Basil's vast correspondence testifies to his practical efforts to reconcile divergent movements in Trinitarian thinking.

Basil is famous as a letter writer and preacher and for his views on the appropriate attitude of Christians toward Hellenistic culture; but his achievement was not less significant as a monastic legislator. His two monastic rules, used by St. Benedict and still authoritative in the Greek Orthodox Church, are tokens of this. Gregory of Nazianzus, too, was an accomplished letter writer, but his numerous, often lengthy poems have a special interest. Dogmatic, historical, and autobiographical, they are often intensely personal and lay bare his sensitive soul. On the other hand, Gregory of Nyssa, much the most speculative of the three, was an Origenist both in his allegorical interpretation of scripture and his eschatology. But he is chiefly remarkable as a pioneer of Christian mysticism, and in his *Life of Moses, Homilies on Canticles,* and other books he describes how the soul, in virtue of having been created in the divine image, is able to ascend, by successive stages of purification, to a vision of God.

Epiphanius of Salamis

A figure who stood in sharp contrast, intellectually and in temperament, to the Cappadocians was their contemporary, Epiphanius of Salamis, in Cyprus. A fanatical defender of the Nicene solution, he was in no sense a constructive theologian like them, but an uncritical traditionalist who rejected every kind of speculation. He was an indefatigable hammer against heretics, and his principal work, the *Panarion* ("Medicine Chest"), is a detailed examination of 80 heresies (20 of them pre-Christian); it is invaluable for the mass of otherwise unobtainable documents it excerpts. Conformably with Epiphanius' contempt for classical learning, the work is written in Greek without any pretension to elegance. His particular bête noire was Origen, to whose speculations and allegorism he traced virtually all heresies.

Monastic literature. From the end of the 3rd century onward, monasticism was one of the most significant manifestations of the Christian spirit. Originating in Egypt and spreading thence to Palestine, Syria, and the whole Mediterranean world, it fostered a literature that illuminates the life of the ancient church.

Both Anthony (*c.* 250–355), the founder of eremitical, or solitary, monasticism in the Egyptian desert, and Ammonas (fl. *c.* 350), his successor as leader of his colony of anchorites (hermits), wrote numerous letters; a handful from the pen of each is extant, almost entirely in Greek or Latin translation of the Coptic originals. Those of Ammonas are particularly valuable for the history of the movement and as reflecting the uncomplicated mysticism that inspired it. The founder of monastic community life, also in Egypt, was Pachomius (*c.* 290–346), and the extremely influential rule that he drew up has been preserved, mainly in a Latin translation made by Jerome.

Influence of monastic literature on ethics and mysticism

Though these and other early pioneers were simple, practical men, monasticism received a highly cultivated convert in 382 in Evagrius Ponticus. He was the first monk to write extensively and was in the habit of arranging his material in groups of a hundred aphorisms, or "centuries," a literary form that he invented and that was to have a great vogue in Byzantine times. A master of the spiritual life, he classified the eight sins that undermine the monk's resolution and also the ascending levels by which the soul rises to wordless contemplation. Later condemned as an Origenist, he was deeply influential in the East, and, through John Cassian, in the West as well.

Side by side with works composed by monks there sprang up a literature concerned with them and the monastic movement. Much of it was biographical, the classic example being Athanasius' *Life of St. Antony.* Sulpicius Severus (*c.* 363–*c.* 420) took this work as his model when early in the 5th century he wrote his *Life of St. Martin of Tours,* the first Western biography of a monastic hero and the pattern of a long line of medieval lives of saints. But it was Palladius (*c.* 363–before 431), a pupil of Evagrius Ponticus, who proved to be the principal historian of primitive monasticism. His *Lausiac History* (so called after Lausus, the court chamberlain to whom he dedicated it), composed about 419/420, describes the movement in Egypt, Palestine, Syria, and Asia Minor. Since much of the work is based on personal reminiscences or information received from observers, it is, despite the legendary character of many of its narratives, an invaluable source book.

Finally, no work so authentically conveys the spirit of Egyptian monasticism as the *Apophthegmata Patrum* ("Sayings of the Fathers"). Compiled toward the end of the 5th century, but using much older material, it is a collection of pronouncements of the famous desert personalities and anecdotes about them. The existing text is in Greek, but it probably derives from an oral tradition in Coptic.

The school of Antioch. Antioch, like Alexandria, was a renowned intellectual centre, and a distinctive school of Christian theology flourished there and in the surrounding region throughout the 4th and the first half of the 5th century. In contrast to the Alexandrian school, it was characterized by a literalist exegesis and a concern for the completeness of Christ's manhood. Little is known of its traditional founder, the martyr-priest Lucian (d. 312), except that he was a learned biblical scholar who revised the texts of the Septuagint and the New Testament. His strictly theological views, though a mystery, must have been heterodox, for Arius, Eusebius of Nicomedia, and other Arians claimed to be his disciples ("fellow Lucianists"), and Bishop Alexander of Alexandria, who denounced them, lists Lucian among those who influenced them. But Eustathius of Antioch, the champion of Nicene orthodoxy, is probably more representative of the school, with his antipathy to what he regarded as Origen's excessive allegorism and his recognition, as against the Arians, of the presence of a human soul in the incarnate Christ.

Literalistic views of the School of Antioch

It was, however, much later in the 4th century, in the person of Diodore of Tarsus (*c.* 330–*c.* 390), that the School of Antioch began to reach the height of its fame. Diodore courageously defended Christ's divinity against Julian the Apostate, the Roman emperor who attempted to revive paganism, and in his lifetime was regarded as a pillar of orthodoxy. Later critics detected anticipations of Nestorianism (the heresy upholding the division of Christ's Person) in his teaching, and as a result his works, apart from some meagre fragments, have perished. They were evidently voluminous and wide-ranging, covering exegesis, apologetics, polemics, and even astronomy; and he not only strenuously opposed Alexandrian allegorism but also expounded the Antiochene *theoria,* or principle for discovering the deeper intention of scripture and at the same time remaining loyal to its literal sense.

Significant Antiochene theologians

In stature and intellectual power Diodore was overshadowed by his two brilliant pupils, Theodore of Mopsuestia (*c.* 350–428/429) and John Chrysostom (*c.* 347–407). Both had also studied under the famous pagan Sophist rhetorician Libanius (314–393), thereby illustrating the cross-fertilization of pagan and Christian cultures at this period. Like Diodore, Theodore later fell under the imputation of Nestorianism, and the bulk of his enormous literary output—comprising dogmatic as well as exegetical works—was lost. Fortunately, the 20th century has seen the recovery of a few important texts in Syriac translations (notably his *Commentary on St. John* and his *Catechetical Homilies*), as well as the reconstruction of the greater part of his *Commentary on the Psalms.* This fresh evidence confirms that Theodore was not only the most acute of the Antiochene exegetes, deploying the hermeneutics (critical interpretive principles) of his school in a thoroughly scientific manner, but also an original theologian who, despite dangerous tendencies, made a unique contribution to the advancement of Christology. His *Catechetical Homilies* are immensely valuable both for understanding his ideas and for the light they throw on sacramental doctrine and liturgical practice.

In contrast to Theodore, John was primarily a preacher; indeed he was one of the most accomplished of Christian orators and amply merited his title "Golden-Mouthed" (*Chrysostomos*). With the exception of a few practical treatises and a large dossier of letters, his writings consist entirely of addresses, the majority being expository of the Bible. There he shows himself a strict exponent of Antiochene literalism, reserved in exploiting even the traditional typology (*i.e.,* treatment of Old Testament events and so forth as prefigurative of the new Christian order) but alert to the moral and pastoral lessons of his texts. This interest, combined with his graphic descriptive powers, makes his sermons a mirror of the social, cultural, and ecclesiastical conditions in contemporary Antioch and Constantinople, as well as of his own compassionate concern as a pastor. Indefatigable in denouncing heresy, he was not an original thinker; on the other hand, he was outstanding as a writer, and connoisseurs of rhetoric have always admired the grace and simplicity of his style in some moods, its splendour and pathos in others.

The last noteworthy Antiochene, Theodoret of Cyrrhus (*c.* 393–*c.* 458), in Syria, was also an elegant stylist. His writings were encyclopaedic in range, but the most memorable perhaps are his *Remedy for Greek Maladies,* the last of ancient apologies against paganism; and his *Ecclesiastical History,* continuing Eusebius' work down to 428. His controversial treatises are also important, for he skillfully defended the Antiochene Christology against the orthodox Bishop Cyril of Alexandria and was instrumental in getting its more valuable features recognized at the Council of Chalcedon. He was a scholar with a comprehensive and eclectic mind, and his large correspondence testifies to his learning and mastery of Greek prose as well as illustrating the history and intellectual life of the age.

The schools of Edessa and Nisibis. Parallel with its richer and better-known Greek and Latin counterparts, an independent Syriac Christian literature flourished inside, and later outside (in Persia), the frontiers of the Roman Empire from the early 4th century onward. Aphraates, an ascetic cleric under whose name 23 treatises written between 336 and 345 have survived, is considered the first Syriac Father. Deeply Christian in tone, these tracts present a primitive theology, with no trace of Hellenistic influence but a firm grasp and skillful use of scripture. Edessa and Nisibis (now Urfa and Nusaybin in southeast Turkey) were the creative centres of this literature. Edessa had been a focus of Christian culture well before 200; the old Syriac version of the New Testament and Tatian's *Diatessaron,* as well as a mass of Syriac apocryphal writings, probably originated there.

Syriac Christian literature

The chief glory of Edessene Christianity was Ephraem Syrus (*c.* 306–373), the classic writer of the Syrian Church who established his school of theology there when Nisibis, its original home and his own birthplace, was ceded to Persia under the peace treaty of 363, after the death of Julian the Apostate. In his lifetime Ephraem had a reputation as a brilliant preacher, commentator, controversialist, and above all, sacred poet. His exegesis shows Antiochene tendencies, but as a theologian he championed Nicene orthodoxy and attacked Arianism. His hymns, many in his favourite seven-syllable metre, deal with such themes as the Nativity, the Epiphany, and the Crucifixion or else are directed against skeptics and heretics. His *Carmina Nisibena* ("Songs of Nisibis") make a valuable source book for historians, especially for information about the frontier wars.

Influence of the Antiochene school of thought in the Syrian East

After Ephraem's death in 373, the school at Edessa developed his lively interest in exegesis and became increasingly identified with the Antiochene line in theology. Among those responsible for this was one of its leading instructors, Ibas (d. 457), who worked energetically translating Theodore of Mopsuestia's commentaries and disseminating his Christological views. His own stance on the now urgent Christological issue was akin to that of Theodoret of Cyrrhus—roughly midway between Nestorius' dualism

and the Alexandrian doctrine of one nature—and he bluntly criticized Cyril's position in his famous letter to Maris (433), the sole survivor (in a Greek translation) of his abundant works; it was one of the Three Chapters anathematized by the second Council of Constantinople (553).

The frankly Antiochene posture typified by Ibas brought the school into collision with Rabbula, bishop of Edessa from 412 to 435, an uncompromising supporter of Cyril and the Alexandrian Christology. As well as writing numerous letters, hymns, and a sermon against Nestorius, Rabbula translated Cyril's *De recta fide* (*Concerning the Correct Faith*) into Syriac and also probably compiled the revised Syriac version of the four Gospels (contained in the Peshitta) in order to oust Tatian's *Diatessaron.* On his death he was succeeded by Ibas, who predictably exerted his influence in an Antiochene direction.

Another eminent Edessene writer was Narses (d. *c.* 503), who became one of the formative theologians of the Nestorian Church. He was the author of extensive commentaries, now lost, and of metrical homilies, dialogue songs, and liturgical hymns. In 447, when a Monophysite reaction set in, he was expelled from Edessa along with Barsumas, the head of the school, but they promptly set up a new school at Nisibis on Persian territory. The school at Edessa was finally closed, because of its Nestorian leanings, by the emperor Zeno in 489, but its offshoot at Nisibis flourished for more than 200 years and became the principal seat of Nestorian culture. At one time it had as many as 800 students and was able to ensure that the then prosperous church in Persia was Nestorian. On the other hand, Philoxenus of Mabbug, who had studied at Edessa in the second half of the 5th century and was one of the most learned of Syrian theologians, was a vehement advocate of Monophysitism. His 13 homilies on the Christian life and his letters reveal him as a fine prose writer; but he is chiefly remembered for the revision of the Syriac translation of the Bible (the so-called Philoxenian version) for which he was responsible and which was used by Syrian Monophysites in the 6th century.

The Chalcedonian Fathers. From about 428 onward Christology became an increasingly urgent subject of debate in the East and excited interest in the West as well. Two broad positions had defined themselves in the 4th century. Among Alexandrian theologians the "Word-flesh" approach was preferred, according to which the Word had assumed human flesh at the Incarnation; Christ's possession of a human soul or mind was either denied or ignored. Antiochene theologians, on the other hand, consistently upheld the "Word-man" approach, according to which the Word had united himself to a complete man; this position ran the risk, unless carefully handled, of so separating the divinity and the humanity as to imperil Christ's personal unity.

Apollinarius the Younger (*c.* 310–*c.* 390) had brilliantly exposed the logical implications of the Alexandrian view; although condemned as a heretic, he had forced churchmen of all schools to recognize, though with varying degrees of practical realism, a human mind in the Redeemer. His writings were systematically destroyed, but the remaining fragments confirm his intellectual acuteness as well as his literary skill. The crisis of the 5th century was precipitated by the proclamation by Nestorius, patriarch of Constantinople—pushing Antiochene tendencies to extremes—of a Christology that seemed to many to imply two Sons. Nestorius held that Mary was not only *Theotokos* ("God-bearing") but also *anthropotokos* ("man-bearing"), though he preferred the term *Christotokos* ("Christ-bearing"). In essence, he was attempting to protect the concept of the humanity of Christ. The controversy raged with extraordinary violence from 428 to 451, when the Council of Chalcedon hammered out a formula that at the time seemed acceptable to most and that attempted to do justice to the valuable insights of both traditions.

The rise of the Christological crisis

A number of theologians and ecclesiastics either prepared the way for or contributed to the Chalcedonian solution. Three who deserve mention are Theodoret of Cyrrhus, Proclus of Constantinople, and John Cassian. The first was probably responsible for drafting the Formula of Union (433) that became the basis of the Chalcedonian Definition. Proclus was an outstanding pulpit orator, and several of his sermons as well as seven letters concerned with the controversy have been preserved; he worked indefatigably to reconcile the warring factions. Cassian prepared the West for the controversy by producing in 430, at the request of the deacon (later pope) Leo, a weighty treatise against Nestorius.

But much the most important, not least because they approached the debate from different standpoints, were Cyril of Alexandria and Pope Leo the Great. Cyril had been the first to denounce Nestorius, and in a whole series of letters and dogmatic treatises he drove home his critique and expounded his own positive theory of hypostatic (substantive, or essential) union. He secured the condemnation of Nestorius at the Council of Ephesus (431), and his own letters were canonically approved at Chalcedon. A convinced adherent of the Alexandrian Word-flesh Christology, he deepened his understanding of the problem as the debate progressed; but his preferred expression for the unity of the Redeemer remained "one incarnate nature of the Word," which he mistakenly believed to derive from Athanasius. Leo provided the necessary balance to this with his famous *Dogmatic Letter,* also endorsed at Chalcedon, which affirmed the coexistence of two complete natures, united without confusion, in the one Person of the Incarnate Word, or Christ.

Contributions of Cyril of Alexandria and Leo the Great

In patristic literature, however, the interest of both Cyril and Leo extends far beyond Christology. Cyril published essays on the Trinitarian issue against the Arians and also commentaries on Old and New Testament books. If the former show little originality, his exegesis marked a reaction against the more fanciful Alexandrian allegorism and a concentration on the strictly typological significance of the text. Leo, for his part, was a notable preacher and one of the greatest of popes. His short, pithy sermons, clear and elegant in style, set a fine model for pulpit oratory in the West; and his numerous letters give an impressive picture of his continuous struggle to promote orthodoxy and the interests of the Roman see.

Non-Chalcedonian Fathers. The Chalcedonian settlement was not achieved without some of the leading participants in the debate that preceded it being branded as heretics because their positions fell outside the limits accepted as permissible. It also left to subsequent generations a legacy of misunderstanding and division.

5th-century heretical literature

The outstanding personalities in the former category were Nestorius and Eutyches. It was Nestorius whose imprudent brandishing of extremist Antiochene theses—particularly his reluctance to grant the title of *Theotokos* to Mary, mother of Jesus—had touched off the controversy. Only fragments of his works remain, for after his condemnation their destruction was ordered by the Byzantine government, but these have been supplemented by the discovery, in a Syriac translation, of his *Book of Heraclides of Damascus.* Written late in his life, when Monophysitism had become the bogey, this is a prolix apology in which Nestorius pleads that his own beliefs are identical with those of Leo and the new orthodoxy. Eutyches, on the other hand, an over-enthusiastic follower of Cyril, was led by his antipathy to Nestorianism into the opposite error of confusing the natures. He contended that there was only one nature after the union of divinity and humanity in the Incarnate Word, and he was thus the father of Monophysitism in the strict, and not merely verbal, sense.

After the Council of Ephesus in 431 the eastern bishops of Nestorian sympathies gradually formed a separate Nestorian Church on Persian soil, with the see of its patriarch at Ctesiphon on the Tigris. Edessa and then Nisibis were its theological and literary centres. But a much wider body of eastern Christians, particularly from Egypt and Palestine, found the Chalcedonian dogma of "two natures" a betrayal of the truth as stated by their hero Cyril. For the next two centuries the struggle between these Monophysites and strict Chalcedonians to secure the upper hand convulsed the Eastern Church. Among the Monophysites it produced theologians of high calibre and literary distinction, notably the moderate Severus of Anti-

och (*c.* 465–538), who while contending stoutly for "one nature after the union" was equally insistent on the reality of Christ's humanity. His contemporary Julian of Halicarnassus taught the more radical doctrine that, through union with the Word, Christ's body had been incorruptible and immortal from the moment of the Incarnation.

In the 7th century, inspired by the need for unity in the face of successive Persian and Arab attacks, an attempt was made to reconcile the Monophysite dissenters with the orthodox Chalcedonians. The formula, which it was thought might prove acceptable to both, asserted that, though Christ had two natures, he had only one activity—*i.e.,* one divine will. This doctrine, Monothelitism, stimulated an intense theological controversy but was subjected to profound and far-reaching criticism by Maximus the Confessor, who perceived that, if Christians are to find in Christ the model for their freedom and individuality, his human nature must be complete and therefore equipped with a human will. The formula was condemned as heretical at the third Council of Constantinople of 680–681.

The post-Nicene Latin Fathers. Latin Christian literature in this period was slower than Greek in getting started, and it always remained sparser. Indeed, the first half of the 4th century produced only Julius Firmicus Maternus, author not only of the most complete treatise on astrology bequeathed by antiquity to the modern world but also of a fierce diatribe against paganism that has the added interest of appealing to the state to employ force to repress it and its immoralities. From Africa, rent asunder by Donatism, the heretical movement that rejected the efficacy of sacraments administered by priests who had denied their faith under persecution, came the measured anti-Donatist polemic of Optatus of Milevis, writing in 366 or 367, whose line of argument anticipates Augustine's later attack against the Donatists.

Much more significant than either, however, was Gaius Marius Victorinus, the brilliant professor whose conversion in 355 caused a sensation at Rome. Obscure but strikingly original in his writings, he was an effective critic of Arianism and sought to present orthodox Trinitarianism in uncompromisingly Neoplatonic terms. His speculations about the inner life of the triune Godhead were to be taken up by Augustine.

Three remarkable figures, all different, dominate the second half of the century. The first, Hilary of Poitiers, was a considerable theologian, next to Augustine the finest produced by the West in the patristic epoch. For years he deployed his exceptional gifts in persuading the anti-Arian groups to abandon their traditional catchwords and rally round the Nicene formula, which they had tended to view with suspicion. Often unfairly described as a popularizer of Eastern ideas, he was an original thinker whose scriptural commentaries and perceptive Trinitarian studies brought fresh insights. The second, Ambrose of Milan, was an outstanding ecclesiastical statesman, equally vigilant for orthodoxy against Arianism as for the rights of the church against the state. Both in his dogmatic treatises and in his largely allegorical, pastorally oriented exegetical works he relied heavily on Greek models. One of the pioneers of Catholic moral theology, he also wrote hymns that are still sung in the liturgy.

Hilary, Ambrose, and Jerome

The third, Jerome, was primarily a biblical scholar. His enormous commentaries are erudite but unequal in quality; the earlier ones were greatly influenced by Origen's allegorism, but the ones written later, when he had turned against Origen, were more literalist and historical in their exegesis. Jerome's crowning gift to the Western Church and Western culture was the Vulgate translation of the Bible. Prompted by Pope Damasus, he thoroughly revised the existing Latin versions of the Gospels; the Old Testament he translated afresh from the Hebrew. His historical and polemical writings (the latter full of sarcasm and invective) are all interesting, and his rich correspondence supremely so. As a stylist he wrote with a verve and brilliance unmatched in Latin patristic literature.

The two foremost Christian Latin poets of ancient times, Prudentius and Paulinus of Nola, also belong to this half-century. Both used the old classical forms with considerable skill, filling them with a fresh Christian spirit. Prudentius' work is both the finer in quality and the more wide-ranging; in his *Psychomachia* ("The Contest of the Soul"), he introduced an allegorical form that made an enormous appeal to the Middle Ages. Paulinus is also interesting for his extensive correspondence, much admired in his own day, which kept him in close touch with many leading Christian contemporaries.

Augustine as the major theologian of the West

All these figures are overshadowed by the towering genius of Augustine (354–430). The range of his writings was enormous: they comprise profound discussions of Christian doctrine (notably his *De Trinitate,* or *On the Trinity*); sustained and carefully argued polemics against heresies (Manichaeism, a dualistic religion; Donatism; and Pelagianism, a view that emphasized free will); exegesis, homilies, and ordinary sermons; and a vast collection of letters. His two best-known works, the *Confessions* and *The City of God,* broke entirely fresh ground, the one being both an autobiography and an interior colloquy between the soul and God, the other perhaps the most searching study ever made of the theology of history and of the fundamental contrast between Christianity and the world. On almost every issue he handled—the problem of evil, creation, grace and free will, the nature of the church—Augustine opened up lines of thought that are still debated. The prose style he used matched the level of his argument, having a rich texture, subtle assonance, and grave beauty that were new in Latin.

In part recovered in recent years, the works of Pelagius (fl. 405–418) show him to have been a writer and thinker of high quality. Early in the 5th century, when the monasteries of southern Gaul became active intellectual centres, Vincent of Lérins and John Cassian published critiques of Augustine's extreme positions on grace and free will, proposing the alternative doctrine called Semi-Pelagianism, which held that humans by their own free will could desire life with God. This in turn was criticized by able writers like Prosper of Aquitaine (*c.* 390–*c.* 463) and the celebrated preacher Caesarius of Arles (470–542) and was condemned at the Council of Orange (529). Cassian, however, a firsthand student of Eastern monasticism, is chiefly important for his studies of the monastic life, based on material collected in the East. The rules he formulated were freely drawn upon a century later by St. Benedict of Nursia, the reformer of Western monasticism, when Benedict composed his famous and immensely influential rule at Monte Cassino.

The decline of Latin and Greek patristic literature

The 6th century marks the final phase of Latin patristic literature, which includes several notable figures, of whom Boethius (480–524), philosopher and statesman, is the most distinguished. His *Consolation of Philosophy* was widely studied in the Middle Ages, but he also composed technically philosophical works, including translations of, and commentaries on, Aristotle. Beside him should be set his longer-lived contemporary, Cassiodorus (*c.* 490–*c.* 585), who, as well as encouraging the study of Greek and Latin classics and the copying of manuscripts in monasteries, was himself the author of theological, historical, and encyclopaedic treatises. Also notable is Venantius Fortunatus (*c.* 540–*c.* 600), an accomplished poet whose hymns, such as "Vexilla regis" ("The royal banners forward go") and "Pange lingua" ("Sing, my tongue, the glorious battle"), are still sung. Finally, Gregory the Great (*c.* 540–604) was so prolific and successful an author as to earn the title of Fourth Doctor of the Latin Church. Although unoriginal theologically and reflecting the credulity of the age, his works (which include the earliest life of St. Benedict) made an enormous appeal to the medieval mind.

Later Greek Fathers. The closing phase of patristic literature lasted longer in the Greek East than in the Latin West, where the decline of culture was hastened by barbarian inroads. But even in the East a slackening of effort and originality was becoming perceptible in the latter half of the 5th century. A clear illustration of this is provided by the practice of substituting chain commentaries composed of excerpts from earlier exegetes and anthologies of opinions of respected past theologians for independent exposition and speculation.

Yet the picture was not altogether dim. In the strictly theological field, Leontius of Byzantium (d. *c.* 545) showed

ability and originality in reinterpreting the Chalcedonian Christology along the lines of St. Cyril with the aid of the increasingly favoured Aristotelian philosophy. Two other writers, very different from him and from each other, revived in the late 5th and early 6th centuries the brilliance of past generations. One was the figure who called himself Dionysius the Areopagite (*c.* 500), the unidentified author of theological and mystical treatises that were destined to have an enormous influence. Based on a synthesis of Christian dogma and Neoplatonism, his work exalts the negative theology (God is understood by what he is not) and traces the soul's ascent from a dialectical knowledge of God to mystical union with him. The other is Romanos Melodos (fl. 6th century), greatest hymnist of the Eastern Church, who invented the kontakion, an acrostic verse sermon in many stanzas with a recurring refrain. The sweep, pathos, and grandeur of his compositions give him a high place of honour among religious poets.

With Maximus the Confessor and John of Damascus the end of the patristic epoch is reached. Maximus was a major critic of Monothelitism; he was also a remarkable constructive thinker whose speculative and mystical doctrines were held in unity by his vision of the incarnation as the goal of history. Writing early in the 8th century, John was chiefly influential through his comprehensive presentation of the teaching of the Greek Fathers on the principal Christian doctrines. But in constructing his synthesis he added at many points a finishing touch of his own; his writings in defense of images, prepared to counter the Iconoclasts (those who advocated destruction of religious images, or icons), were original and important; and he was the author of striking poems, some of which found a place in the Greek liturgy.

THE CHARACTER OF THE HERITAGE

The vitality of patristic literature

For 400 or 500 years, when secular culture was slowly but steadily in decline, the patristic writers breathed new life into the Greek and Latin languages and created Syriac as a literary medium. Even when the period came to an end, the halt was really only a temporary pause until the impulses behind it could force other outlets. The literature of the later Byzantine Empire looked back to and drew nourishment from the golden centuries of the Fathers, while Latin Christian letters experienced more than one renascence in the Middle Ages.

The range and variety, too, of the literature are impressive. Its overwhelmingly theological concern necessarily imposed understandable but serious limitations, but, when these have been allowed for, the Christian writers must be acknowledged to have been remarkably successful at molding the traditional literary forms to their new purposes and also at improvising fresh ones adapted to their special situations. Aesthetically considered, patristic literature contains much that is mediocre and even shoddy, but also a great deal that by any standards reaches the heights. And it has a unique interest as the creation of an immensely dynamic and far-reachingly important religious movement during the centuries when it could dominate the whole of life and society. (J.N.D.K.)

Christian philosophy

It has been debated whether there is anything that is properly called Christian philosophy. Christianity is not a system of ideas but a religion, a way of salvation. But as a religion becomes a distinguishable strand of human history, it inevitably absorbs philosophical assumptions from its environment and generates new philosophical constructions and arguments both in the formation of doctrines and in their defense against philosophical objections. These two topics cannot be kept entirely separate, however, for philosophical criticism from both within and without the Christian community has influenced the development of its beliefs.

HISTORY OF THE INTERACTIONS OF PHILOSOPHY AND THEOLOGY

As the Christian movement expanded beyond its original Jewish nucleus into the Greco-Roman world, it had to understand, explain, and defend itself in terms that were intelligible in an intellectual milieu largely structured by Greek philosophical thought. By the 2nd century AD several competing streams of Greek and Roman philosophy—Middle Platonism, Neoplatonism, Epicureanism, Stoicism—had to a great extent flowed together into a common worldview that was basically Neoplatonic, though enriched by the ethical outlook of the Stoics. This constituted the broad intellectual background for most educated people throughout the Roman Empire, functioning in a way comparable, for example, to the pervasive contemporary Western secular view of the universe as an autonomous system within which everything can in principle be understood scientifically.

Influence of Neoplatonism

Some of the Neoplatonic themes that provided intellectual material for Christian and non-Christian thinkers alike in the early centuries of the Common Era were a hierarchical conception of the universe, with the spiritual on a higher level than the physical; the eternal reality of such values as goodness, truth, and beauty and of the various universals that give specific form to matter; and the tendency of everything to return to its origin in the divine reality. The early Christian Apologists were at home in this thought-world, and many of them used its ideas and assumptions both in propagating the Gospel and in defending it as a coherent and intellectually tenable system of belief. Their most common attitude was to accept the prevailing Neoplatonic worldview as basically valid and to present Christianity as its fulfillment, correcting and completing rather than replacing it. Philosophy, they thought, was to the Greeks what the Law was to the Jews—a preparation for the Gospel; and several Apologists agreed with the Jewish writer Philo that Greek philosophy must have received much of its wisdom from Moses. Tertullian (*c.* 155/160–after 220) and Tatian (*c.* 120–173), on the other hand, rejected pagan learning and philosophy as inimical to the Gospel; and the question has been intermittently discussed by theologians ever since whether the Gospel completes and fulfills the findings of human reason or whether reason is itself so distorted by sin as to be incapable of leading toward the truth.

Greek philosophy, then, provided the organizing principles by which the central Christian doctrines were formulated. It is possible to distinguish between, on the one hand, first-order religious expressions, directly reflecting primary religious experience, and, on the other, the interpretations of these in philosophically formulated doctrines whose articulation both contributes to and is reciprocally conditioned by a comprehensive belief-system. Thus the primitive Christian confession of faith, "Jesus is Lord," expressed the Disciples' perception of Jesus as the one through whom God was transformingly present to them and to whom their lives were accordingly oriented in complete trust and commitment. The interpretive process whereby the original experience developed a comprehensive doctrinal superstructure began with the application to Jesus of the two distinctively Jewish concepts of the expected messiah and the Son of man who was to come on the last day and also of the son of God metaphor, which was commonly applied in the ancient world to individuals, whether kings or holy men, who were believed to be close to God. It continued on a more philosophical level with the use, in the Gospel According to John, of the idea of the Logos, drawn both from the Hebraic notions of the Wisdom and the Word of God and from the Greek notion of the Logos as the universal principle of rationality and self-expression. As Jesus, son of God, became Christ, God the Son, the second Person of the Trinity, he was identified with the Logos.

Emergence of official doctrine

For several generations there was great variety and experimentation in Christian thinking. But as Christianity was legally recognized under Constantine in 313 and then became the sole official religion of the Roman Empire under Theodosius, its doctrines had to be formalized and agreed throughout the church. This pressure for uniformity provoked intense debates, which lasted for several generations before the great ecumenical councils (principally Nicaea, 325; Constantinople, 381; and Chalcedon, 451) finally established the official versions of the doctrines of Christ and

the Trinity; to differ from these was heresy. The key ideas in terms of which these Christological and Trinitarian debates were conducted and their conclusions formulated were the Greek concepts of ousia (nature or essence) and hypostasis (entity, used as virtually equivalent to *prosōpon*, person). (In Latin these terms became *substantia* and *persona*.) Christ was said to have two natures, one of which was of the same nature (*homoousios*) as the Father, whereas the other was of the same nature as humanity; and the Trinity was said to consist of one ousia in three hypostases. The Platonic origin of this conceptuality is clear in the explanation of the Cappadocian Fathers that the Father, Son, and Holy Spirit share the same divine ousia in the way Peter, James, and John shared the same humanity. (On the doctrines of Incarnation and the Trinity, see above *Christian doctrine*.)

Another prime example of the influence of Neoplatonism on Christian thought occurred in the response of the greatest of the early Christian thinkers, St. Augustine (354–430), to the perennially challenging question of how it is that evil exists in a world created by an all-good and all-powerful God. Augustine's answer (which, as refined by later thinkers, remained the standard Christian answer until modern times) includes both theological aspects (the ideas of the fall of angels and then of humans, of the redemption of some by the cross of Christ, and of the ultimate disposal of souls in eternities of bliss and torment) and philosophical aspects. The basic philosophical theme, drawn directly from Neoplatonism, is one that the American philosopher Arthur Lovejoy, in *The Great Chain of Being* (1936), called the principle of plenitude. This is the idea that the best possible universe does not consist only of the highest kind of creature, the archangels, but contains a maximum richness of variety of modes of being, thus realizing every possible kind of existence from the highest to the lowest. The result is a hierarchy of degrees both of being and of goodness, for the identity of being and goodness was another fundamental idea received by Augustine from Neoplatonism and in particular from Plotinus (205–270). God, as absolute being and goodness, stands at the summit, with the great chain of being descending through the many forms of spiritual, animal, and plant life down to lifeless matter. This conception explains why there are lower forms of existence—dogs, snakes, insects, viruses—as well as higher. Each embodies being and is therefore good on its own level; and together they constitute a universe whose rich variety is beautiful in the sight of God. Evil only comes about when creatures at any level forfeit the distinctive goodness with which the Creator had endowed them. Evil is thus negative or privative, a lack of proper good rather than anything having substance in its own right. This, too, was a theme that had been taken over from Neoplatonism by a number of earlier Christian writers. And if evil is not an entity, or substance, it follows that it was not a part of God's original creation. It consists instead in the going wrong of something that is in itself good, though (because made out of nothing) also mutable. Augustine locates the origin of this going-wrong in the sinful misuse of freedom by some of the angels and then by the first humans. His theodicy is thus a blend of Neoplatonic and biblical themes and shows clearly the immense influence of Neoplatonism upon Christian thought during its early formative period.

The origin of evil

Augustine himself, together with Christian thinking as a whole, departed from Neoplatonism at one crucial point. Neoplatonism saw the world as continuous in being with the ultimate divine reality, the One. The One, in its limitless plenitude of being, overflows into the surrounding void, and the descending and attenuating degrees of being constitute the many-leveled universe. In contrast to this emanationist conception Augustine held that the universe is a created realm, brought into existence by God out of nothing (ex nihilo). It has no independent power of being, or aseity, but is through and through contingent, absolutely dependent upon the creative divine power. Further, Augustine was clear that the *nihil* out of which God created was not any kind of preexistent matter or chaos, but that "out of nothing" simply means "not out of anything" (*De natura boni*). This understanding of creation, entailing the universe's total emptiness of independent self-existence and yet its ultimate goodness as the free expression of God's creative love, is perhaps the most distinctively Christian contribution to metaphysical thought. It goes beyond the earlier Hebraic understanding in making explicit the ex nihilo character of creation in contrast to the emanationism of the Neoplatonic thought-world. This basic Christian idea entails the value of creaturely life and of the material world itself, its dependence upon God, and the meaningfulness of the whole temporal process as fulfilling an ultimate divine purpose.

Augustine's view of creation ex nihilo

Modern Christian treatments of the idea of creation ex nihilo have detached it from a literal use of the Genesis creation myth. The idea of the total dependence of the universe upon God is neutral as to whether it had a temporal beginning; nor does it in any way preclude the development of the universe in its present phase from the "big bang" onward, including the evolution of the forms of life on Earth. Although creation ex nihilo (a term apparently first introduced into Christian discourse by Irenaeus in the 2nd century) remains the general Christian conception of the relation between God and the physical universe, some recent Christian thinkers have substituted the view (derived from Alfred North Whitehead and developed by Charles Hartshorne) that God, instead of being its transcendent Creator, is an aspect of the universe itself, being either the inherent creativity in virtue of which it is a living process or a deity of finite power who seeks to lure the world into ever more valuable forms.

Although Neoplatonism was the major philosophical influence on Christian thought in its early period and has never ceased to be an important element within it, Aristotle was also always known, though at first only as a logician. But in the 12th and 13th centuries his writings on physics, metaphysics, and ethics became available in Latin, translated either from the Greek or from Arabic sources, and they were crucial for the greatest of the medieval Christian thinkers, St. Thomas Aquinas (*c.* 1225–74). One of the Aristotelian themes that influenced Thomas was that knowledge is not innate but is gained from the reports of the senses and from logical inference from self-evident truths. (Thomas, however, in distinction from Aristotle, added divinely revealed propositions to self-evident truths in forming his basis for inference.) Thomas also received from Aristotle the conception of metaphysics as the science of being. His doctrine of analogy, according to which statements about God are true analogically rather than univocally, was likewise inspired by Aristotle, as were his distinctions between act and potency, essence and existence, substance and accidents, and the active and passive intellect and his view of the soul as the "form" of the body.

Aristotelian themes in Christian philosophy

Thomas Aquinas' system, however, was by no means simply Aristotle Christianized. He did not hesitate to differ from "the Philosopher," as he called him, when the Christian tradition required this; for whereas Aristotle had been concerned to understand how the world functions, Thomas was also concerned, more fundamentally, to explain why it exists.

With the gradual breakdown of the medieval worldview—its assumptions undermined by the Renaissance, the Reformation, the rise of modern science, and the spread of a new spirit of exploration and free inquiry—the nature of the philosophical enterprise began to change. The French thinker René Descartes (1596–1650) is generally regarded as the father of modern philosophy, and in the new movements of thought that began with him philosophy became less a matter of building and defending comprehensive metaphysical systems, or imagined pictures of the universe, and more a critical probing of presuppositions, categories of thought, and modes of reasoning and an inquiry into what it is to know, how knowledge and belief are arrived at in different areas of life, how well various kinds of beliefs are grounded, and how thought is related to language. There has long ceased to be a generally accepted philosophical framework, comparable with Neoplatonism, in terms of which Christianity can appropriately be expressed and defended. There is instead a plurality of philosophical perspectives and methods—analytic, positivist, phenomenological, idealist, pragmatist,

and existentialist. Thus modern Christianity, having inherited a body of doctrines developed in the framework of ancient worldviews that are now virtually defunct, lacks any philosophy of comparable status in terms of which to rethink its beliefs. In this situation some theologians have turned to existentialism, which is not so much a philosophical system as a hard-to-define point of view and style of thinking. Indeed, the earlier existentialists, such as the Danish philosopher Søren Kierkegaard (1813–55), vehemently rejected the idea of a metaphysical system—in particular, for 19th-century existentialists, the Hegelian system—though some later ones, such as the German philosopher Martin Heidegger (1889–1976), have developed their own systems. Existentialists are identified by the appearance in their writings of one or more of a number of loosely related themes. These include the significance of the concrete individual in contrast to abstractions and general principles; a stress upon human freedom and choice and the centrality of decision, and hence a view of religion as ultimate commitment; a preference for paradox rather than rational explanation; and the highlighting of certain special modes of experience that cut across ordinary consciousness, particularly a generalized anxiety or dread and the haunting awareness of mortality. Existentialists have been both atheists (*e.g.,* Friedrich Nietzsche and Jean-Paul Sartre) and Christians (*e.g.,* Kierkegaard, the Protestant Rudolf Bultmann, and the Roman Catholic Gabriel Marcel). It would be difficult to identify any doctrines that are common to all these thinkers. Existentialist themes have also been incorporated into systematic Christian theologies (*e.g.,* by John Macquarrie).

Influence of existentialism

Others have sought to construct theologies in the mold of 19th-century German idealism (*e.g.,* Paul Tillich); some, as process theologians, in that of the early 20th-century British mathematician and metaphysician Alfred North Whitehead (*e.g.,* Charles Hartshorne on the doctrine of God, John Cobb on Christology); some, the liberation theologians, in highly pragmatic and political terms (*e.g.,* Juan Luis Segundo, Gustavo Gutiérrez); and some, as feminist theologians, in terms of the newly awakened self-consciousness of women and the awareness of a distorting patriarchial influence on all past forms of Christian thought (*e.g.,* Rosemary Ruether, Elizabeth Fiorenza). Most theologians, however, have continued to accept the traditional structure of Christian beliefs. The more liberal among them have sought to detach these from the older conceptualities and to reformulate them so as to connect with modern consciousness (*e.g.,* Friedrich Schleiermacher, Albrecht Ritschl, Adolf von Harnack, Karl Rahner, Gordon Kaufman); while the more conservative have sought to defend the traditional formulations within an increasingly alien intellectual environment (*e.g.,* B.B. Warfield, Charles Hodge, Karl Barth, Cornelis Berkouwer).

Effect of the sciences on modern Christian thought

Of the factors forming the intellectual environment of Christian thought in the modern period, perhaps the most powerful have been the physical and human sciences. The former have compelled the rethinking of certain Christian doctrines, as astronomy undermined the assumption of the centrality of the Earth in the universe, as geologic evidence concerning its age rendered implausible the biblical chronology, and as biology located humanity within the larger evolution of the forms of life on Earth. The human sciences of anthropology, psychology, sociology, and historical research have suggested possible naturalistic explanations of religion itself based, for example, upon the projection of desire for a cosmic father figure, the need for socially cohesive symbols, or the power of royal and priestly classes. Such naturalistic interpretations of religion, together with the ever-widening scientific understanding of the physical universe, have prompted some Christian philosophers to think of the religious ambiguity of the universe as a totality that can, from the human standpoint within it, be interpreted in both naturalistic and religious ways, thus providing scope for the exercise of faith as a free response to the mystery of existence.

FAITH AND REASON

Different conceptions of faith cohere with different views of its relation to reason or rationality. The classic medieval understanding of faith, set forth by Thomas Aquinas, saw it as the belief in revealed truths on the authority of God as their ultimate source and guarantor. Thus, though the ultimate object of faith is God, their revealer, its immediate object is the body of propositions articulating the basic Christian dogmas. Such faith is to be distinguished from knowledge. Whereas the propositions that are the objects of scientia, or knowledge, compel belief by their self-evidence or their demonstrability from self-evident premises, the propositions accepted by faith do not thus compel assent but require a voluntary act of trusting acceptance. As unforced belief, faith is "an act of the intellect assenting to the truth at the command of the will" (*Summa theologiae,* II/II, Q. 4, art. 5); and it is because this is a free and responsible act that faith is one of the virtues. It follows that one cannot have knowledge and faith at the same time in relation to the same proposition; faith can only arise in the absence of knowledge. Faith also differs from mere opinion, which is inherently changeable. Opinions are not matters of absolute commitment but allow in principle for the possibility of doubt and change. Faith, as the wholehearted acceptance of revealed truth, excludes doubt.

Faith distinguished from knowledge

In the wider context of his philosophy Thomas Aquinas held that human reason, without supernatural aid, can establish the existence of God and the immortality of the soul; though these are also revealed, for acceptance by faith, for the benefit of those who cannot or do not engage in such strenuous intellectual activity. Faith, however, extends beyond the findings of reason in accepting such further truths as the triune nature of God and the divinity of Christ. Thomas thus supported the general (though not universal) Christian view that revelation supplements, rather than cancels or replaces, the findings of sound philosophy.

From a skeptical point of view, which does not acknowledge divine revelation, this Thomist conception amounts to faith as belief that is unevidenced or that is stronger than the evidence warrants, the gap being filled by the believer's own will to believe. As such it attracts the charge that belief upon insufficient evidence is always wrong.

Faith as a rational wager

In response to this kind of attack the French philosopher Blaise Pascal (1623–62) proposed a voluntarist defense of faith as a rational wager. Pascal assumed, in disagreement with Thomas Aquinas but in agreement with much modern thinking, that divine existence can neither be proved nor disproved; and he reasoned that if one decides to believe in God and to act on this basis, one gains eternal life if right but loses little if wrong, whereas if one decides not to believe, one gains little if right but may lose eternal life if wrong. In these circumstances, he concluded, the rational course is to believe. The argument has been criticized theologically for presupposing an unacceptable image of God as rewarding such calculating worship and also on the philosophical ground that it is too permissive in that it could justify belief in the claims, however fantastic, of any person or group who threatened nonbelievers with damnation or other dangerous consequences.

The American philosopher William James (1842–1910) refined this approach by limiting it, among matters that cannot be determined by proof or evidence, to belief-options that one has some real inclination or desire to accept, carry momentous implications, and are such that a failure to choose constitutes a negative choice. Theistic belief is for many people such an option, and James claimed that they have the right to make the positive decision to believe and to proceed in their lives on that basis. Either choice involves unavoidable risks: on the one hand the risk of being importantly deluded and on the other the risk of missing a limitlessly valuable truth. In this situation each individual is entitled to decide which risk to run. This argument has also been criticized as being too permissive and as constituting in effect a license for wishful believing, but its basic principle can perhaps be validly used in the different context of opting to base beliefs upon one's religious experience.

The element of risk in faith as a free cognitive choice was emphasized, to the exclusion of all else, by Kierkegaard in his idea of the leap of faith. He believed that without

Kierkegaard's leap of faith

risk there is no faith, and that the greater the risk the greater the faith. Faith is thus a passionate commitment, not based upon reason but inwardly necessitated, to that which can be grasped in no other way.

The epistemological character of faith as assent to propositions, basic to the Thomist account, is less pronounced in the "betting one's life" conceptions of Pascal and James in that these accept not a system of doctrines but only the thought of God as existing—though of course that thought itself has conceptual and hence implicitly propositional content. Kierkegaard's self-constituting leap of faith likewise only implicitly involves conceptual and propositional thought. The same is true of the account of faith based upon Ludwig Wittgenstein's concept of seeing-as (*Philosophical Investigations,* 1953). Wittgenstein pointed to the epistemological significance of puzzle pictures, such as the ambiguous duck-rabbit that can be seen either as a duck's head facing one way or a rabbit's head facing another way. The enlarged concept of experiencing-as (developed by the British philosopher John Hick) refers to the way in which an object, event, or situation is experienced as having a particular character or meaning such that to experience it in this manner involves being in a dispositional state to behave in relation to the object or event, or within the situation, in ways that are appropriate to its having that particular character. All conscious experience is in this sense experiencing-as. The application of this idea to religion suggests that the total environment is religiously ambiguous, capable of being experienced in both religious and naturalistic ways. Religious faith is the element of uncompelled interpretation within the distinctively religious ways of experiencing—for theism, experiencing the world or events in history or in one's own life as mediating the presence and activity of God. In ancient Hebrew history, for example, events that are described by secular historians as the effects of political and economic forces were experienced by some of the great prophets as occasions in which God was saving or punishing, rewarding or testing, the Israelites. In such cases religious does not replace secular experiencing-as but supervenes upon it, revealing a further order of meaning in the events of the world. And the often unconscious cognitive choice whereby someone experiences religiously constitutes, on this view, faith in its most epistemologically basic sense.

For these voluntarist, existentialist, and experiential conceptions of faith the place of reason in religion, although important, is secondary. Reason cannot directly establish the truth of religious propositions. Its function is rather to defend the rational propriety of trusting one's deeper intuitions or one's religious experience and basing one's beliefs and life upon them. These schools of thought assume that the philosophical arguments for and against the existence of God are inconclusive, and that the universe is capable of being consistently thought of and experienced in both religious and naturalistic ways. This assumption, however, runs counter to the long tradition of natural theology.

CHRISTIAN PHILOSOPHY AS NATURAL THEOLOGY

Natural theology is generally characterized as the project of establishing religious truths by rational argument and without reliance upon alleged revelations, its two traditional topics being the existence of God and the immortality of the soul.

Arguments for the existence of God. *The design (or teleological) argument.* St. Paul, with many others in the Greco-Roman world, believed that the existence of God is evident from the appearances of nature: "Ever since the creation of the world his invisible nature, namely, his eternal power and deity, has been clearly perceived in the things that have been made" (Romans 1:20). The most popular, because the most accessible, of the theistic arguments is that which identifies evidences of design in nature, inferring from them a divine designer. The argument was propounded by medieval Christian thinkers and was developed in great detail in 17th- and 18th-century Europe by such writers as Robert Boyle, John Ray, Samuel Clarke, and William Derham and at the beginning of the 19th century by William Paley. Such writers asked: Is not the eye as manifestly designed for seeing, and the ear for hearing, as a pen for writing or a clock for telling the time; and does not such design imply a designer? The fact that the universe as a whole is a coherent and efficiently functioning system likewise, in this view, indicates a divine intelligence behind it.

Evidence of God in nature

This kind of argument was powerfully criticized by the Scottish philosopher David Hume in his *Dialogues Concerning Natural Religion* (1779). Hume granted that the world constitutes a more or less smoothly functioning system; indeed, he points out, it could not exist otherwise. He suggests, however, that this may have come about as a result of the chance permutations of particles falling into a temporary or permanent self-sustaining order, which thus has the appearance of design. A century later the idea of order without design was rendered more plausible by Charles Darwin's discovery that the adaptations of the forms of life are a result of the natural selection of inherited characteristics having positive, and the elimination of those having negative, survival value within a changing environment. Hume also pointed out that, even if one could infer an intelligent designer of the world, one would not thereby be entitled to claim that such a designer is the infinitely good and powerful Creator who is the object of Christian faith. For the world is apparently imperfect, containing many inbuilt occasions of animal pain and human suffering, and one cannot legitimately infer a greater perfection in the cause than is observed in the effect.

In the 20th century, however, the design argument has been reformulated in more comprehensive ways, particularly by the British philosophers Frederick R. Tennant (*Philosophical Theology,* 1928–30) and Richard Swinburne (using Bayes's probability theorem in *The Existence of God,* 1979), taking account not only of the order and functioning of nature but also of the "fit" between human intelligence and the universe, whereby one can understand its workings, as well as human aesthetic, moral, and religious experience. There are also attempts to show that the evolution of the universe, from the "big bang" of some 15,000,000,000 years ago to the present state that includes conscious life, required the conjunction of so many individually improbable factors as to be inexplicable except as the result of a deliberate coordinating control. If, for example, the initial heat of the expanding universe, or its total mass, or the strength of the force of gravity, or the mass of neutrinos, or the strength of the strong nuclear force, had been different by a small margin, there would have been no galaxies, no stars, no planets, and hence no life. Surely, it is argued, all this must be the work of God creating the conditions for human existence.

Probability arguments

These probability arguments have, however, been strongly criticized. A basic consideration relevant to them all is that there is by definition only one universe, and it is difficult to see how its existence, either with or without God, can be assessed as having a specific degree of probability in any objective sense. It can of course be said that any form in which the universe might be is statistically enormously improbable as it is only one of a virtual infinity of possible forms. But its actual form is no more improbable, in this sense, than innumerable others. It is only the fact that humans are part of it that makes it seem so special, requiring a transcendent explanation. The design argument is thus an area in which debate continues.

The cosmological argument. St. Thomas Aquinas gave the first-cause argument and the argument from contingency—both forms of cosmological reasoning—a central place for many centuries in the Christian enterprise of natural theology. (Similar arguments were also used in parallel strands of Islāmic philosophy.) Thomas' formulations (*Summa theologiae,* I, Q. 2, art. 3) have been refined in modern neo-Thomist discussions and continue to be topics of Christian philosophical reflection.

The first-cause argument begins with the fact that there is change in the world. A change is always the effect of some cause or causes. Each cause is itself the effect of a further cause or set of causes; this chain moves in a series that either never ends or is completed by a first cause, which must be of a radically different nature in that it is not itself caused. Such a first cause is an important aspect, though not the entirety, of what Christianity means by God.

Change and causation

The argument from contingency follows by another route the same basic movement of thought from the nature of the world to its ultimate ground. It starts with the fact that everything in the world is contingent for its existence upon other factors. Its presence is thus not self-explanatory but can only be understood by reference beyond itself to prior or wider circumstances that have brought it about. These other circumstances are likewise contingent; they too point beyond themselves for the ground of their intelligibility. If this explanatory regress is unending, explanation is perpetually postponed and nothing is finally explained. The existence of anything and everything thus remains ultimately unintelligible. But rational beings are committed to the search for intelligibility and cannot rest content until it is found. The universe can only finally be intelligible as the creation of an ontologically necessary being who is eternal and whose existence is not contingent upon anything else. This is also part of what Christianity has meant by God.

Criticism of these arguments points to the possibility that there is no first cause because the universe had no beginning, having existed throughout time, and is thus itself the necessary being that has existed eternally and without dependence upon anything else. Proponents of the cosmological argument reply that the existence of such a universe, as a procession of contingent events without beginning, would still be ultimately unintelligible. On the other hand, a personal consciousness and will, constituting a self-existent Creator of the universe, would be intrinsically intelligible; for human beings have experience in themselves of intelligence and free will as creative. Critics respond that insofar as the argument is sound it leaves one with the choice between believing that the universe is ultimately intelligible, because created by a self-existent personal will, or accepting that it is finally unintelligible, simply the ultimate given brute fact. The cosmological argument does not, however, compel one to choose the first alternative; logically, the second remains equally possible.

The ontological argument. The ontological argument, which proceeds not from the world to its Creator but from the idea of God to the reality of God, was first clearly formulated by St. Anselm (1033/34–1109) in his *Proslogion* (1077–78). Anselm began with the concept of God as that than which nothing greater can be conceived (*aliquid quo nihil majus cogitari possit*). To think of such a being as existing only in thought and not also in reality involves a contradiction. For an X that lacks real existence is not that than which no greater can be conceived. A yet greater being would be X with the further attribute of existence. Thus the unsurpassably perfect being must exist—otherwise it would not be unsurpassably perfect.

The necessity of God's existence

This argument has intrigued philosophers ever since. After some discussion in the 13th century it was reformulated for the modern world by Descartes in his *Meditations* (1641). Descartes made explicit the assumption, implicit in Anselm's reasoning, that existence is an attribute that a given X can have or fail to have. It follows from this—together with the assumption that existence is an attribute that is better to have than to lack—that God, as unsurpassably perfect, cannot lack the attribute of existence.

It was the assumption that existence is a predicate that has, in the view of most subsequent philosophers, proved fatal to the argument. The criticism was first made by Descartes's contemporary Pierre Gassendi and later and more prominently by the German philosopher Immanuel Kant (1724–1804) in his *Critique of Pure Reason* (1781). Putting their point as it has come to be further clarified by Bertrand Russell and others in the 20th century, to say that something with stated properties (whether it be a triangle, defined as a three-sided plane figure, or God, defined as an unsurpassably perfect being) exists, is not to attribute to it a further property, namely existence, but is to assert that the concept (of a triangle, or of God) is instantiated—that there actually are instances of that concept. But whether or not a given concept is instantiated is a question of fact. It cannot be determined a priori but only by whatever is the appropriate method for discovering a fact of that kind. This need for, in the broadest sense, observation cannot be circumvented by writing existence into the definition of the concept ("an existing three-sided plane figure," "an existing unsurpassably perfect being"), for the need arises again as the question of whether this enlarged concept is instantiated.

In the 20th century several Christian philosophers (notably Charles Hartshorne, Norman Malcolm, and Alvin Plantinga) have rediscovered and claimed validity for a second form of Anselm's argument. This hinges upon "necessary existence," a property with even higher value than "existence." A being that necessarily exists cannot coherently be thought not to exist. And so God, as the unsurpassably perfect being, must have necessary existence—and therefore must exist. This argument, however, has been criticized as failing to observe the distinction between logical and ontological, or factual, necessity. Logically necessary existence, it is said, is an incoherent idea, for logical necessity applies to the relations between concepts, not to their instantiation. God's necessity, then, must be an ontologically, or factually, rather than a logically, necessary existence: God exists as the ultimate fact, without beginning or end and without depending upon anything else for existence. But whether this concept of an ontologically necessary being is instantiated cannot be determined a priori. It cannot be validly inferred from the idea of an eternal and independent being that there actually is such a being.

Logical and ontological necessity

Moral arguments. Moral theistic argument belongs primarily to the modern world and perhaps reflects the modern lack of confidence in metaphysical constructions. Kant, having rejected the cosmological, ontological, and design proofs, argued in the *Critique of Practical Reason* (1788) that the existence of God, though not directly provable, is a necessary postulate of the moral life. To take seriously the awareness of a categorical imperative to act rightly is to commit oneself to work for an ideal state of affairs in which perfect goodness and happiness coincide. But as this universal apportioning of happiness to virtue is beyond human power, a divine agent capable of bringing it about must be assumed.

Other Christian thinkers, particularly during the 19th and early 20th centuries, have developed the theme that to accept the absolute demands of ethical obligation is to presuppose that this is a morally structured universe; and that this in turn implies a personal God whose commands are reflected in the human conscience. It cannot be proved that this is such a universe, it is said, but it is inevitably assumed in acknowledging the claims of morality.

The basic criticism of all attempts to trace ethical obligation to a transcendent divine source has been that it is possible to account for morality without going beyond the human realm. It is argued that the exigencies of communal life require agreed codes of behaviour, which become internalized in the process of socialization as moral laws; and the natural affection that develops among humans produces the more occasional sense of a call to heroic self-sacrifice on behalf of others. It seems, then, that the moral arguments for divine existence do not rise to the level of strict proofs.

Arguments from religious experience and miracles. Religious experience is used in Christian apologetics in two ways—in the argument from religious experiences to God as their cause and in the claim that it is (in the absence of contrary indications) as reasonable to trust religious as it is to trust nonreligious experience in forming beliefs about the total environment. (The first use is considered here among the traditional theistic arguments; for the second, see below *Contemporary discussions*.)

The argument maintains that special episodes, such as seeing visions of Christ or Mary or hearing a voice speaking with apparently divine authority, as well as the more pervasive experience of "living in God's presence" or of "absolute dependence upon a higher power," constitute evidence of God as their source. The criticism of this reasoning is that although such experiences may be accepted as having occurred, their cause might be purely natural. To establish that the experiences are real, as experiences, is not to establish that they are caused by an infinite, omnipotent, omniscient, divine being. As Thomas Hobbes succinctly put it, when someone says that God has spoken

to him in a dream, this "is no more than to say he dreamed that God spake to him" (*Leviathan,* Pt. III, ch. 32).

God as the agent of miracles

The analogous argument, from miracles to God as their cause, is more complex, involving two sets of problems. The argument may assert that the children of Israel were miraculously rescued from Egypt or Jesus was miraculously raised from the dead and therefore that God must exist as the agent of these miracles. The first problem concerns the reports. Whereas in the case of private religious experiences the skeptic (to whom the argument is addressed) may well be willing to grant that such experiences occurred, in the case of public miracles the skeptic will require adequate evidence for the described event; and this is not forthcoming for the classic miracle stories referring to alleged extraordinary events of many centuries ago. There are, however, well-evidenced contemporary and recent accounts of "miraculous" healings and other remarkable happenings. On the assumption that some of these, and also some of the classic miracle stories, are historically accurate, the second problem arises. How can it be established that these events were caused by supernatural divine intervention rather than by the operation of natural psychic laws, such as seem to be indicated by the phenomena of telepathy and telekinesis?

Once again, any kind of strict proof seems to be lacking. These arguments can, however, still be seen as displaying aspects of the explanatory power of the idea of God. Divine activity is not the only possible way of understanding the ordered and developing character of the universe, its contingent existence, the unconditional claims of morality, or the occurrence of religious experiences and "miracles." Nevertheless, the concept of deity offers a possible, satisfying answer to the fundamental questions to which these various factors point. They may thus be said to open the door to rational theistic belief—but still leaving the nonbeliever waiting for a positive impetus to go through that door. Some of the contemporary work by Christian philosophers has been in search of such a positive impetus.

The immortality of the soul. Human beings seem always to have had some notion of a shadowy double that survives the death of the body. But the idea of the soul as a mental entity, with intellectual and moral qualities, interacting with a physical organism but capable of continuing after its dissolution, derives in Western thought from Plato and entered into Judaism during approximately the last century before the Common Era and thence into Christianity. In Jewish and Christian thinking it has existed in tension with the idea of the resurrection of the person conceived as an indissoluble psychophysical unity. Christian thought gradually settled into a pattern that required both of these apparently divergent ideas. At death the soul is separated from the body and exists in a conscious or unconscious disembodied state. But on the future Day of Judgment souls will be re-embodied (whether in their former but now transfigured earthly bodies or in new resurrection bodies) and will live eternally in the heavenly kingdom.

Within this framework philosophical discussion has centred mainly on the idea of the immaterial soul and its capacity to survive bodily death. Plato, in the *Phaedo,* argued that the soul is inherently indestructible. To destroy something, including the body, is to disintegrate it into its constituent elements; but the soul, as a mental entity, is not composed of parts and is thus an indissoluble unity. Although Thomas Aquinas' concept of the soul, as the "form" of the body, was derived from Aristotle rather than Plato, he too argued for its indestructibility (*Summa theologiae,* I, Q. 76, art. 6). The French philosopher Jacques Maritain (1882–1973), a modern Thomist, summarized the conclusion as follows: "A spiritual soul cannot be corrupted, since it possesses no matter; it cannot be disintegrated, since it has no substantial parts; it cannot lose its individual unity, since it is self-subsisting, nor its internal energy since it contains within itself all the sources of its energies" (*The Range of Reason,* 1952). But though it is possible to define the soul in such a way that it is incorruptible, indissoluble, and self-subsisting, critics have asked whether there is any good reason to think that souls as thus defined exist. If, on the other hand, the soul means the conscious mind or personality—something whose immortality would be of great interest to human beings—this does not seem to be an indissoluble unity. On the contrary, it seems to have a kind of organic unity that can vary in degree but that is also capable of fragmentation and dissolution.

The indestructibility of the soul

Much modern philosophical analysis of the concept of mind is inhospitable to the idea of immortality, for it equates mental life with the functioning of the physical brain (see MIND, THE PHILOSOPHY OF). Impressed by evidence of the dependence of mind on brain, some Christian thinkers have been willing to accept the view—corresponding to the ancient Hebrew understanding—of the human being as an indissoluble psychophysical unity, but these thinkers have still maintained a belief in immortality, not as the mind surviving the body, but as a divine resurrection or re-creation of the living body-mind totality. Such resurrection persons would presumably be located in a space different from that which they now inhabit and would presumably undergo a development from the condition of a dying person to that of a viable inhabitant of the resurrection world. But all theories in this area carry with them their own difficulties, and discussion continues.

Kant offered a different kind of argument for immortality—as a postulate of the moral life. The claim of the moral law demands that human beings become perfect. This is something that can never be finally achieved but only asymptotically approached, and such an unending approach requires the unending existence of the soul. This argument also is open to criticism. Are humans indeed subject to a strict obligation to attain moral perfection? Might not their obligation, as finite creatures, be to do the best they can? But this does not seem to entail immortality.

It should be noted that in the case of all these arguments, both for the immortality of the soul and for the existence of God, the debate has been as much among Christian philosophers as between them and non-Christian skeptics. It is by no means the case that Christian thinkers have all regarded the project of natural theology as viable. There have indeed been, and are, many who hold that divine existence can be definitively proved or shown to be objectively probable. But there are many others who not only hold that the attempted proofs all require premises that a disbeliever is under no rational obligation to accept but who also question the evidentialist assumption that the only route to rational theistic belief is by inference from previously accepted evidence-stating premises.

CONTEMPORARY DISCUSSIONS

Contemporary discussion among Christian philosophers is predominantly epistemological. Among Roman Catholic thinkers it includes the original work of Bernard Lonergan in *Insight* (1957), which has stimulated considerable discussion. Lonergan argued that the act of understanding, or insight, is pivotal for the apprehension of reality, and that it implies in the long run that the universe is itself due to the fiat of an "unrestricted act of understanding," which is God. Other Roman Catholic thinkers have continued to refine and extend the Thomistic approach, particularly the idea of analogical predication in statements about God. Others, in common with non-Catholic philosophers, have discussed the traditional divine attributes—omniscience, omnipotence, eternity, immutability, personality, goodness. The concept of a finite deity developing through time has also been proposed (*e.g.,* by Charles Hartshorne) to meet objections to some of these concepts: If God is immutable, how can God be aware of successive events in time? If God has absolute self-existence, how can God respond with sympathy to the pains of creaturely life? Others have defended the traditional attributes as logically coherent, both individually and in their relationship to one another, and as allowing for divine awareness of the created universe, God's activity in history, and divine sympathy with human suffering.

Influence of logical positivism

Perhaps the largest body of work, however, has been generated in dialogue with the new linguistic turn of philosophy in the English-speaking world, particularly since World War II, concentrating on the analysis of language in its various uses. The logical positivist movement originated in the 1920s with the Vienna Circle. Although

mainly concerned with the philosophy of science, it posed by implication a major challenge to the logical meaningfulness of religious language. The positivist position, in its developed form, was that a statement has factual meaning only if it is capable in principle of being verified or falsified, or at least in some degree confirmed or disconfirmed, within human experience; otherwise it is meaningless, or cognitively vacuous. In the years immediately after World War II this account of factual meaning was applied (*e.g.,* by Antony Flew) to theological statements, raising such questions as: What observable difference does it make whether it is true or false that "God loves us"? Whatever tragedies occur, do not the faithful still maintain their belief, adding perhaps that the divine love is beyond human comprehension? But if it is not possible to conceive of circumstances in which "God loves us" would have to be judged false, is not the statement factually empty, or meaningless?

This challenge evoked three kinds of response. Some Christian philosophers have declared it to be a non-challenge, on the ground that the positivists never succeeded in finding a precise formulation of the verification criterion that was fully satisfactory even to themselves. Others have held that this does not block the central thrust of the positivist challenge. Does it really make no difference within actual or possible human experience whether or not God exists and loves us; and if so, is not the significance of the belief thereby fatally damaged? Among those who felt it necessary to face this challenge, one group granted that theological statements lack factual meaning and suggested that their proper use lies elsewhere, as expressing a way of looking at the world (*e.g.,* Richard M. Hare) or a moral point of view and commitment (*e.g.,* R.B. Braithwaite). The other group claimed that theism is ultimately open to experiential confirmation. The theory of eschatological verification (developed by John Hick) holds that the belief in future postmortem experiences will be verified if true (though not falsified if false), and that in a divinely governed universe such experiences will take forms confirming theistic faith. Thus although the believer and the disbeliever do not have different expectations about the course of earthly history, they do expect the total course of the universe to be radically different.

In the late 20th century, under the stimulus of Wittgenstein's posthumously published works, attention has been directed to the multiple legitimate uses of language in the various language games developed within different human activities and forms of life; and it has been urged (*e.g.,* by D.Z. Phillips) that religious belief has its own autonomous validity, not subject to verificationist or scientific or other extraneous criteria. Statements about God and eternal life do not make true-or-false factual claims but express, in religious language, a distinctive attitude to life and way of engaging in it. This suggestion forms part of the broader non-realist interpretation of religion, holding that its beliefs do not refer to putative transcendent realities but are instead expressive of human ideals, desires, hopes, attitudes, and intentions. Such thinking goes back to the German philosopher Ludwig Feuerbach (*The Essence of Christianity,* 1841) in the 19th century and to George Santayana, John Dewey, and J.H. Randall, Jr., in the early 20th century and is advocated today by some Christian writers, notably D.Z. Phillips and Don Cupitt. According to them, true Christianity consists in the inner purity of an unself-centred attitude to life and does not involve belief in the objective reality of God or of a life after death. The criticism this view inevitably attracts is that to deny the transcendent reference of religious language empties it of any substantial meaning. The issue is the focus of considerable contemporary discussion.

In addition to this and other work concerning religious language there has been a renewal of fundamental discussion of Christian, and more broadly religious, epistemology. The natural theology tradition held that, in order to be rational, religious belief must be supported by adequate evidences or arguments. It was assumed that God's existence must be validly inferred from generally acceptable premises. This evidentialist principle has been questioned, however, not only by such earlier thinkers as Pascal and William James but also by a number of contemporary Christian philosophers. Evidentialist thinking was foundationalist in granting that there are some beliefs that can be reasonably held directly and not by inference from other evidence-stating beliefs. Thomas Aquinas, for example, recognized self-evident truths and the reports of the senses as basic in the sense that they do not need support from other beliefs. They thus provide the foundations on which a belief structure can properly be built. Belief in the existence of God was not regarded as basic or foundational in this way but was thought to require adequate evidence or arguments. It has been argued (by Alvin Plantinga) that the range of properly basic beliefs is wider than classic foundationalism had recognized. It can include not only beliefs about the past and the existence of other persons but also belief in the reality of God. Such beliefs can be basic (*i.e.,* not inferred), and they are properly basic if held in appropriate circumstances. Thus, the belief that "There is a tree before me" is properly basic for one who is having the experience of seeing a tree; and the belief that "God exists" is properly basic for one who experiences God's judgment, forgiveness, love, claim, providential care, or some other mode of divine presence.

Challenges to the evidentialist principle

Discussion of this proposal centres upon the criteria for proper basicality: In what circumstances is it appropriate, and in what circumstances not, to hold the basic belief in God or the basic beliefs of other religions or of the naturalistic worldviews?

A related contemporary development, pursued by William Alston and others, is the claim that religious experience constitutes an entirely proper basis for religious beliefs. The claim is not that one can validly infer God as the cause of theistic religious experience, but that one who participates in such experience is entitled to trust it as a ground for belief. It is argued that human beings all normally operate with a "principle of credulity" whereby they take what seems to be so as indeed so, unless they have some positive reason to doubt it. Accordingly, one who has the experience of living in the presence of God can properly proceed in both thought and life on the basis that God is real. Such belief inevitably involves epistemic risk—the risk of error versus the risk of missing the truth. But perhaps the right to believe that was defended by William James applies in this situation.

The principle of credulity

The discussion focuses on the analogies between religious forms of experience and the kinds of sensory experience in relation to which the principle of credulity is virtually universally accepted. It is uncontroversially proper to hold beliefs reflecting sense experience, but what of beliefs reflecting religious experience? Whereas all human beings hold the former and could not survive without doing so, the latter type of belief seems to be optional. Although beliefs regarding physical objects can be empirically confirmed or disconfirmed, religious beliefs cannot. Acknowledging these significant differences, some Christian philosophers have argued that they are the kinds of differences that are to be expected, given the difference between the human relationship to the world and to God. It is necessary to human existence as physical organisms that a consciousness of the material environment should be forced upon human beings. On the other hand, it is necessary for existence as relatively autonomous and responsible beings that consciousness of God should not be forced upon them, for to be compulsorily aware of God's universal presence as limitless goodness and power, making a total claim upon human life, would deprive them of creaturely freedom. Humans are accordingly set at an epistemic distance from God that is overcome only by faith, which can be identified with the voluntary interpretive element within the experience of God's presence.

The central Christian doctrine of the divinity of Christ is another topic of current discussion. Philosophical questions concerning this were debated intensively in the 3rd to 5th centuries, as noted above, in terms of the key notion of ousia/substantia. The concept of substance, however, although confidently used throughout the medieval period, has been widely questioned within modern thought and no longer figures in the distinctively 20th-century streams of philosophy. There have consequently

been a variety of attempts, in which theology and philosophy mingle inextricably, to find an interpretation that is intelligible today. Instead of the basically static notion of substance—Jesus qua human being of human substance and qua divine of God's substance—many have preferred the more dynamic idea of divine action. From this point of view Jesus was divine in the sense that God was acting redemptively through him; or, instead of a *homo-ousion*, identity of substance, between Jesus and the heavenly Father, there was a *homo-agapion*, an identity of divine loving. Others, however, have criticized such alternatives to the older substance language, often on the ground that, whereas "being of the same substance as" is an all-or-nothing concept, divine activity in and through a human life is capable of degrees, so that the divinity of Christ may in principle be de-absolutized. The intertwining theological and philosophical issues continue to be strongly debated.

Questions of religious pluralism

The problems of religious pluralism are increasingly being seen as requiring the attention of Christian philosophers. One reason arises from the kind of apologetic described above, hinging upon the reasonableness of basing beliefs upon religious experience. It is evident that there are many forms of religious experience, giving rise to many forms of religious belief. There is considerable variety within the Christian tradition itself, and in the world as a whole Muslim forms of religious experience give rise to and justify Islāmic beliefs, Jewish forms of experience to Jewish beliefs, Hindu to Hindu beliefs, Buddhist to Buddhist beliefs, and so on. These different belief systems include mutually incompatible doctrines. Thus the experiential solution to the problem of justifying Christian beliefs has given rise to a new problem constituted by the conflicting truth-claims of the different religious traditions.

The other reason the great world faiths provide new issues for Christian philosophy is that some of their belief systems challenge long-standing Christian assumptions. Whereas Judaism and Islām raise theological questions, the most challenging philosophical issues are raised by Buddhism. The belief in God as the personal ultimate is challenged by the idea of the ultimacy of the nonpersonal *dharma-kāya*. The idea of the immortal soul is challenged by the *anattā* ("no soul") doctrine, with its claim that the personal mind or soul is not an enduring substance but a succession of fleeting moments of consciousness. And yet Buddhism, teaching as it does doctrines that are radically different from those of the Christian faith, also challenges Christianity by the centrality within it of compassion, peaceableness, and a respect for all life.

These and other issues raised by the fact of religious plurality are ones that Christian philosophers have only begun to face but that suggest the possibility of major developments in Christian thinking. (J.Hi.)

Christian mysticism

Christian mysticism refers to the human being's direct experience or consciousness of ultimate reality, understood as God within the context of Christian faith. The essence of mysticism is the sense of some form of contact with the divine or transcendent, frequently understood in its higher forms as involving union with God. Mysticism has played an important role in the history of Christian religion, and it has once again become a noticeably living influence in recent times.

In the modern period mysticism has been studied from many perspectives: psychological, comparativist, philosophical, and theological, to name only the most vital. The mystical text has been the subject of new attention sparked by hermeneutical and deconstructionist philosophies. Among the theoretical questions that have been much debated are such issues as whether mysticism constitutes the core or essence of personal religion or whether it is better viewed as one element interacting with others in the formation of concrete religions. Those who emphasize a strong distinction between mystical experience and subsequent interpretation tend to search for a common core of all mysticism; others insist that experience and interpretation cannot be so easily sundered and that mysticism is in most cases tied to a specific religion and contingent upon its teachings. Both those who search for the common core, such as the British philosopher Walter T. Stace, and those who emphasize the differences among forms of mysticism, such as the British historian of religion Robert C. Zaehner, have made use of typologies of mysticism, often based on the contrast between introvertive and extrovertive mysticism developed by the comparativist Rudolf Otto. Studies have criticized the typological approach, but many scholars still find it useful.

The cognitive status of mystical knowing and its clash with the mystics' claims about the ineffability of their experiences have also been topics of interest for modern students of mysticism. Among the most important investigations of mystical knowing are those of the Belgian Jesuit Joseph Maréchal and the French philosophers Henri Bergson and Jacques Maritain.

The relation between mysticism and morality has been a topic of scholarly debate since the time of William James, but certain questions have concerned Christian mystics for centuries. Does mystical experience always confirm traditional religious ideas about right and wrong, or is mysticism totally independent of moral issues? The problems regarding mysticism are fairly easy to identify; definitive solutions seem far off.

Mysticism's role in Christianity

The role of mysticism in Christianity has been variously evaluated by modern theologians. Many Protestant thinkers, from Albrecht Ritschl and Adolf von Harnack through Karl Barth and Rudolf Bultmann, have denied mysticism an integral role in the Christian religion, claiming that mystical union was a Greek import incompatible with saving faith in the Gospel word. Other Protestant theologians, such as Ernst Troeltsch in *The Social Teaching of the Christian Churches* (trans. 1931) and Albert Schweitzer in *The Mysticism of Paul the Apostle* (trans. 1931), were more sympathetic. Anglican thinkers, especially William R. Inge, Evelyn Underhill, and Kenneth E. Kirk, championed the importance of mysticism in Christian history. Orthodox Christianity has given mysticism so central a role in Christian life that all theology in the Christian East by definition is mystical theology, as the Russian emigré thinker Vladimir Lossky showed in *The Mystical Theology of the Eastern Church* (trans. 1957).

The most extensive theological discussions of mysticism in Christianity have been found in modern Roman Catholicism. In the first half of the 20th century Neoscholastic authors—invoking the authority of Thomas Aquinas and the Spanish mystics Teresa of Ávila and John of the Cross—debated whether mystical contemplation was the goal of all Christians or a special grace offered only to a few. The discrimination of the various forms of prayer and the distinction between acquired contemplation, for which the believer could strive with the help of grace, and infused contemplation, which was a pure and unmerited gift, framed much of this discussion. Other Roman Catholic theologians, such as Cuthbert Butler in *Western Mysticism* (1922) and Anselm Stolz in *Theologie der Mystik* (1936), broke with the narrow framework of Neoscholasticism to consider the wider scriptural and patristic tradition. In the second half of the century Roman Catholic theologians including Karl Rahner and Hans Urs von Balthasar addressed key theological issues in mysticism, such as the relation of mystical experience to the universal offer of grace and the status of non-Christian mysticism.

HISTORY OF CHRISTIAN MYSTICISM

Early church. Although the essence of mysticism is the sense of contact with the transcendent, mysticism in the history of Christianity should not be understood merely in terms of special ecstatic experiences but as part of a religious process lived out within the context of the Christian community. From this perspective mysticism played a vital part in the early church. Early Christianity was a religion of the spirit that expressed itself in the heightening and enlargement of human consciousness. It is clear from the Synoptic Gospels (*e.g.*, Matthew 11:25–27) that Jesus was thought to have enjoyed a sense of special contact with God. In the primitive church an active part was played by prophets, who were believed to be recipients of a revelation coming directly from the Holy Spirit.

The mystical aspect of early Christianity finds its fullest expression in the letters of Paul and the Gospel According to John. For Paul and John mystical experience and aspiration are always for union with Christ. It was Paul's supreme desire to know Christ and to be united with him. The recurring phrase, "in Christ," implies personal union, a participation in Christ's death and Resurrection. The Christ with whom Paul is united is not the man Jesus who is known "after the flesh." He has been exalted and glorified, so that he is one with the Spirit.

Christ-mysticism

Christ-mysticism finds renewed embodiment in the Gospel According to John, particularly in the farewell discourse (chapters 14–16), where Jesus speaks of his impending death and of his return in the Spirit to unite himself with his followers. In the prayer of Jesus in chapter 17 there is a vision of an interpenetrating union of souls in which all who are one with Christ share his perfect union with the Father.

In the early Christian centuries the mystical trend found expression not only in the stream of Pauline and Johannine Christianity (as in the writings of Ignatius of Antioch and Irenaeus of Lyon) but also in the Gnostics (early Christian heretics who viewed matter as evil and the spirit as good). Scholars still debate the origins of Gnosticism, but most Gnostics thought of themselves as followers of Christ, albeit a Christ who was pure spirit. The mysticism of the Gnostics can be seen in the religion of Valentinus, who was excommunicated in about AD 150. He believed that human beings are alienated from God because of their spiritual ignorance; Christ brings them into the gnosis (esoteric revelatory knowledge) that is union with God. Valentinus held that all human beings come from God and that all will in the end return to God. Other Gnostic groups held that there were three types of people—"spiritual," "psychic," and "material"—and that only the first two can be saved. The *Pistis Sophia* (3rd century) is preoccupied with the question of who finally will be saved. Those who are saved must renounce the world completely and follow the pure ethic of love and compassion. They will then be identified with Jesus and become rays of the divine Light.

Eastern Christianity. The classic forms of Eastern Christian mysticism appeared toward the end of the 2nd century, when the mysticism of the early church began to be expressed in categories of thought explicitly dependent on the Greek philosophical tradition of Plato and his followers. This intermingling of primitive Christian themes with Greek speculative thought has been variously judged by later Christians, but contemporaries had no difficulty in seeing it as proof of the new religion's ability to adapt and transform all that was good in the world. The philosophical emphasis on the unknowability of God found an echo in many texts of the Old and New Testaments, affirming that the God of Abraham and the Father of Jesus could never be fully known. The understanding of the role of the preexistent Logos, or Word, of the Gospel According to John in the creation and restoration of the universe was clarified by locating the Platonic conception of Ideas in the Logos. Greek emphasis on the vision or contemplation (*theōria*) of God as the goal of human blessedness found a scriptural warrant in the sixth Beatitude: "Blessed are the pure in heart, for they shall see God" (Matthew 5:8). The notion of deification (*theiosis*) fit with the New Testament emphasis on becoming sons of God and such texts as 2 Peter 1:4, which talked about sharing in the divine nature. These ecumenical adaptations later provided an entry for the language of union with God, especially after the notion of union became more explicit in Neoplatonism, the last great pagan form of philosophical mysticism. Many of these themes are already present in germ in the works of Clement of Alexandria, written in about 200. They are richly developed in the thought of Origen, the greatest Christian writer of the pre-Constantinian period and the earliest major speculative mystic in Christian history.

Origen and monasticism

Origen's mystical theology, however, required a social matrix in which it could take on life as formative and expressive of Christian ideals. This was the achievement of early Christian monasticism, the movement into the desert that began to transform ideals of Christian perfection at the beginning of the 4th century. The combination of the religious experience of the desert Christians and the generally Origenist theology that helped shape their views created the first great strand of Christian mysticism, one that remains central to the East and that was to dominate in the West until the end of the 12th century. Though not all the Eastern Christian mystical texts were deeply imbued with Platonism, all were marked by the monastic experience.

The first great mystical writer of the desert was Evagrius Ponticus (346–399), whose works were influenced by Origen. His writings show a clear distinction between the ascetic, or "practical," life and the contemplative, or "theoretical," life, a distinction that was to become classic in Christian history. His disciple, John Cassian, conveyed Evagrian mysticism to the monks of western Europe, especially in the exposition of the "degrees of prayer" in his *Collations of the Fathers,* or *Conferences.* Gregory of Nyssa, the younger brother of Basil, sketched out a model for progress in the mystical path in his *Life of Moses* and, following the example of Origen, devoted a number of homilies to a mystical interpretation of the Song of Solomon, showing how the book speaks both of Christ's love for the church and of the love between the soul and the Divine Bridegroom.

Perhaps the most influential of all Eastern Christian mystics wrote in the 5th or 6th century in the name of Dionysius the Areopagite, Paul's convert at Athens. He was probably a Syrian monk. In the chief works of this Pseudo-Dionysius, *Mystical Theology* and *On the Divine Names,* the main emphasis was on the ineffability of God ("the Divine Dark") and hence on the "apophatic" or "negative" approach to God. Through a gradual process of ascension from material things to spiritual realities and an eventual stripping away of all created beings in "unknowing," the soul arrives at "union with Him who transcends all being and all knowledge" (*Mystical Theology,* chapter 1). The writings of the Pseudo-Dionysius also popularized the threefold division of the mystical life into purgative, illuminative, and unitive stages. Later Eastern mystical theologians, especially Maximus the Confessor in the 7th century, adopted much of this thought but corrected it with greater Christological emphasis, showing that union with God is possible only through the action of the God-man.

Eastern mystics distinguish between the essence of God and divine attributes, which they regard as energies that penetrate the universe. Creation is a process of emanation, whereby the divine Being is "transported outside of Himself . . . to dwell within the heart of all things . . . " (Pseudo-Dionysius the Areopagite, *On the Divine Names,* iv. 13). The divinization of humanity is fundamental to Eastern mysticism.

Divinization of humanity

Divinization comes through contemplative prayer, and especially through the method of Hesychasm (from *hesychia,* "stillness") adopted widely by the Eastern monks. The method consisted in the concentration of the mind on the divine Presence, induced by the repetition of the "Jesus-prayer" (later formalized as "Lord Jesus Christ, Son of God, have mercy on me a sinner"). This culminated in the ecstatic vision of the divine Light and was held to divinize the soul through the divine energy implicit in the name of Jesus. Much of this program can already be found in the writings of Symeon the New Theologian (*c.* 949–1022), a monk of Constantinople. It reached its theologically most evolved form in Gregory Palamas (1296–1359), who defended the Hesychast tradition against its opponents. This rich form of Christian mysticism found a new centre in the Slavic lands after the conquest of the Greek East by the Turks. It experienced a flowering in Russia, beginning with the *Philokalia,* an anthology of ascetical and mystical texts first published in 1782, and continuing to the Revolution of 1917. Eastern Christian mysticism is best known in the West through translations of the anonymous 19th-century Russian text *The Way of the Pilgrim,* but noted Russian mystics, such as Seraphimof Sarov (1759–1833) and John of Kronshtadt (1829–1909), are gradually becoming better known in the West.

In the Eastern as in the Western Church mystical reli-

gion received at times heretical expressions. These trends begin with the Messalians (Syriac for "praying people") of the 4th century, who were accused of neglecting the sacraments for ceaseless prayer and of teaching a materialistic vision of God. Later mystics, both orthodox and suspect, have been accused of Messalianism. Other mystic sects grew up in Russia. The Dukhobors, who originated in the 18th century among the peasants, resemble the Quakers in their indifference to outer forms, standing for the final authority of the Inner Light. They were severely persecuted in Russia and migrated to Canada early in the 20th century. (S.Sp./B.J.McG.)

Western Catholic Christianity. The founder of Latin Christian mysticism is Augustine, bishop of Hippo (354–430). In his *Confessions* Augustine mentions two experiences of "touching" or "attaining" God. Later, in the *Literal Commentary on Genesis,* he introduced a triple classification of visions—corporeal, spiritual (*i.e.,* imaginative), and intellectual—that influenced later mystics for centuries. Although he was influenced by Neoplatonist philosophers such as Plotinus, Augustine did not speak of personal union with God in this life. His teaching, like that of the Eastern Fathers, emphasized the ecclesial context of Christian mysticism and the role of Christ as mediator in attaining deification, or the restoration of the image of the Trinity in the depths of the soul. The basic elements of Augustine's teaching on the vision of God, the relation of the active and contemplative lives, and the sacramental dimension of Christian mysticism were summarized by Pope Gregory I the Great in the 6th century and conveyed to the medieval West by many monastic authors.

Two factors were important in the development of this classic Augustinian form of Western mysticism. The first was the translation of the writings of Pseudo-Dionysius the Areopagite and other Eastern mystics by the 9th-century thinker Johannes Scotus Erigena. In combining the Eastern and Western mystical traditions, Erigena created the earliest version of a highly speculative negative mysticism that was later often revived. The other new moment began in the 12th century when new forms of religious life burst on the scene, especially among monks and those priests who endeavoured to live like monks (the canons). The major schools of 12th-century mysticism were inspired by new trends in monastic piety, especially those introduced by Anselm of Canterbury, but they developed these in a systematic fashion unknown to previous centuries. The great figures of the era, especially Bernard of Clairvaux among the Cistercians and Richard of Saint-Victor among the canons, have remained the supreme teachers of mystical theology in Catholic Christianity, along with the Spanish mystics of the 16th century.

Monastic piety

What the Cistercian and Victorine authors contributed to the development of Catholic mysticism was, first, a detailed study of the stages of the ascent of the soul to God on the basis of a profound understanding of the human being as the image and likeness of God (Genesis 1:26) and, second, a new emphasis on the role of love as the power that unites the soul to God. Building on both Origen and Augustine, Bernard and his contemporaries made affective, or marital, union with God in oneness of spirit (1 Corinthians 6:17) a central theme in Western mysticism, though along with Gregory the Great they insisted that "love itself is a form of knowing," that is, of vision or contemplation of God.

The great mystics of the 12th century contributed to an important expansion of mysticism in the following century. For the first time mysticism passed beyond the confines of the monastic life, male writers, and the Latin language. This major shift is evident not only in the life of Francis of Assisi, who emphasized the practical following of Jesus and came to be identified with him in a new form of Christ-mysticism, manifested in his reception of the stigmata, or wounds of the crucified Christ, but also in the remarkable proliferation of new forms of religious life and mystical writing in the vernacular on the part of women. Though female mystics such as Hildegard von Bingen were not unknown in the 12th century, the 13th century witnessed a flowering of interest in mysticism among women, evident in the Flemish Hadewijch of Brabant, the German Mechthild von Magdeburg, the French Marguerite Porete, and the Italians Clare of Assisi and Àngela da Foligno.

Among the important themes of the new mysticism of the 13th century was a form of Dionysian theology in which the stage of divine darkness surpassing all understanding was given a strong affective emphasis, as well as the emergence of an understanding of union with God that insisted upon a union of indistinction in which God and the soul become one without any medium. The first of these tendencies is evident in the writings of Bonaventure, the supreme master of Franciscan mysticism; the second is present in some of the women mystics but finds its greatest proponent in the Dominican Meister Eckhart, who was condemned for heresy in 1329.

Eckhart's mysticism

Eckhart taught that "God's ground and the soul's ground is one ground," and the way to the realization of the soul's identity with God lay less in the customary practices of the religious life than in a new state of awareness achieved through radical detachment from all created things and a breakthrough to the God beyond God. Though Eckhart's thought remained Christological in its emphasis on the necessity for the "birth of Son in the soul," his expressions of the identity between the soul that had undergone this birth and the Son of God seemed heretical to many. Without denying the importance of the basic structures of the Christian religion, and while insisting that his radical preaching to the laity was capable of an orthodox interpretation, Eckhart and the new mystics of the 13th century were a real challenge to traditional Western ideas of mysticism. Their teaching seemed to imply an autotheism in which the soul became identical with God, and many feared that this might lead to a disregard of the structures and sacraments of the church as the means to salvation and even to an antinomianism that would view the mystic as exempt from the moral law. The Council of Vienne condemned such errors in 1311, shortly after Marguerite Porete was burned as a heretic for continuing to disseminate her book, *The Mirror of Simple Souls.* The council associated these views with the Beguines, groups of religious women who did not live in cloister or follow a recognized rule of life. In the centuries that followed, some mystics were condemned and others executed on this basis, though evidence for a widespread "mystical heresy" is lacking.

The great mystical writers of the late Middle Ages, however, took pains to prove their orthodoxy. Eckhart's followers among the Rhineland mystics, especially Heinrich Suso and Johann Tauler, defended his memory but qualified his daring language. Texts such as the anonymous *Theologia Germanica* of the late 14th century, which reflects the ideas of the loose groups of mystics who called themselves the Friends of God, conveyed this German mysticism to the Reformers. In the Low Countries, the rich mystical literature that developed reached its culmination in writings of Jan van Ruysbroeck (1293–1381). In Italy two remarkable women, Catherine of Siena in the 14th century and Catherine of Genoa in the 15th, made important contributions to the theory and practice of mysticism. The 14th century also saw the "Golden Age" of English mysticism, as conveyed in the writings of the hermit Richard Rolle; the canon Walter Hilton, who wrote *The Scale* (or *Ladder*) *of Perfection;* the anonymous author of *The Cloud of Unknowing;* and his contemporary, the visionary recluse Mother Julian of Norwich, whose *Revelations of Divine Love* is unsurpassed in English mystical literature. Julian's meditations on the inner meaning of her revelations of the crucified Christ express the mystical solidarity of all humanity in the Redeemer, who is conceived of as a nurturing mother.

16th-century Spanish mystics

In the 16th century the centre of Roman Catholic mysticism shifted to Spain, the great Roman Catholic power at the time of the Reformation. Important mystics came both from the traditional religious orders, such as Francis de Osuna among the Franciscans, Luis de León among the Augustinians, and Luis de Grenada among the Dominicans, and from the new orders, as with Ignatius of Loyola, the founder of the Jesuits. The two pillars of Spanish mysticism, however, were Teresa of Avila (1515–

82) and her friend John of the Cross (1542–91), both members of the reform movement in the Carmelite order. Teresa's *Life* is one of the richest and most convincing accounts of visionary and unitive experiences in Christian mystical literature; her subsequent synthesis of the seven stages on the mystical path, *The Interior Castle,* has been used for centuries as a basic handbook. John of the Cross was perhaps the most profound and systematic of all Roman Catholic mystical thinkers. His four major works, *The Dark Night of the Soul, The Ascent of Mount Carmel, The Spiritual Canticle,* and *The Living Flame of Love,* constitute a full theological treatment of the active and passive purgations of the sense and the spirit, the role of illumination, and the unification of the soul with God in spiritual marriage.

In the 17th century France took the lead with figures such as Francis of Sales, Pierre de Bérulle, Brother Lawrence (the author of *The Practice of the Presence of God*), and Marie Guyard. At this time concentration on the personal experience of the mystic as the source for "mystical theology" (as against the common scriptural faith and sacramental life of the church) led to the creation of mysticism as a category and the description of its adherents as mystics. This century also saw renewed conflict over mysticism with the rise of the Quietist controversy. A Spaniard resident in Rome, Miguel de Molinos, author of the popular *Spiritual Guide* (1675), was condemned for his doctrine of the "One Act," that is, the teaching that the will, once fixed on God in contemplative prayer, cannot lose its union with the divine. In France Mme Guyon and her adviser, François Fénelon, archbishop of Cambrai, were also condemned for Quietist tendencies emphasizing the role of pure love to the detriment of ecclesiastical practice. These debates cast a pall over the role of mysticism in Roman Catholicism into the 20th century, though important mystics continued to be found. (B.J.McG.)

Protestant Christianity. The chief representatives of Protestant mysticism are the continental "Spirituals," among whom Sebastian Franck (*c.* 1499–*c.* 1542), Valentin Weigel (1533–88), and Jakob Böhme (1575–1624) are especially noteworthy. Among traditional Lutherans Johann Arndt (1555–1621) in his *Four Books on True Christianity* took up many of the themes of medieval mysticism in the context of Reformation theology and prepared the way for the spiritual revival known as Pietism, within which such mystics as Count von Zinzendorf flourished. In England the Anglican divines known as the Cambridge Platonists, the Quakers headed by George Fox (1624–91), and William Law (1686–1761) were important. In Holland a mystical group known as Collegiants, similar to the Quakers, broke away from the Remonstrant (Calvinist) Church. Other mystical bodies were the Schwenckfeldians, founded by Kaspar Schwenckfeld, and the Family of Love, founded in Holland by Hendrik Niclaes early in the 16th century before moving to England about 1550. The religion of the Ranters and other radical Puritans in 17th-century England had mystical aspects.

The cardinal feature of Protestant mysticism is the emphasis laid on the divine element in humanity variously known as the "spark" or "ground" of the soul, the "divine image" or "holy self," the "Inner Light," or the "Christ within." This was one of the essential elements of Rhineland mysticism and shows the connection between medieval and Reformation mysticism. For Böhme and the Spirituals, essential reality lies in the ideal world, which Böhme described as "the uncreated Heaven." Böhme took over the Gnostic belief that the physical world arose from a primeval fall, renewed with the Fall of Adam. His teaching was the main formative influence on the developed outlook of William Law and William Blake (1757–1827).

The mystical view of sin

For Protestant as well as for Roman Catholic mystics, sin is essentially the assertion of the self in its separation from God. The divine life is embodied in "the true holy self that lies within the other" (Böhme, *First Epistle*). When that self is manifested, there is a birth of God (or of Christ) in the soul. Protestant mystics rejected the Lutheran and Calvinist doctrine of the total corruption of human nature. William Law remarked: "the eternal Word of God lies hid in thee, as a spark of the divine nature" (*The Spirit of Prayer,* I.2.). "The eternal Word of God" is the inner Christ, incarnate whenever people rise into union with God. By the Spirituals Christ was viewed as the ideal humanity born in God from all eternity. This conception received its greatest emphasis with Kaspar Schwenckfeld, who, unlike Protestant mystics generally, taught that humans as created beings are totally corrupt; salvation means deliverance from the creaturely nature and union with the heavenly Christ.

Protestant mystics explicitly recognize that the divine Light or Spark is a universal principle. Hans Denck in the early 16th century spoke of the witness of the Spirit in "heathens and Jews." Sebastian Franck, like the Cambridge Platonists, found divine revelation in the work of the sages of Greece and Rome. George Fox appealed to the conscience of the American Indians as a proof of the universality of the Inner Light. William Law described non-Christian saints as "apostles of a Christ within." Protestant mystics stated plainly that, for the mystic, supreme authority lies of necessity not in the written word of Scripture but in the Word of God in the self. Fox said: "I saw, in that Light and Spirit that was before the Scriptures were given forth" (*Journal,* chapter 2). It was especially on this ground that the mystics came into conflict with the established church, whether Roman Catholic or Protestant.

The Ranters provide a good example of the conflict between mysticism and established religion. They held, with Fox and Hendrik Niclaes, that perfection is possible in this life. Puritan leaders under the Commonwealth denounced them for their "blasphemous and execrable opinions," and there was, no doubt, an antinomian tendency among them that rejected the principle of moral law. Some rejected the very notion of sin and believed in the universal restoration of all things in God.

STAGES OF CHRISTIAN MYSTICISM

Christian mystics have described the stages of the return of the soul to God in a variety of ways. Following the Belgian Jesuit Joseph Maréchal, it can be suggested that Christian mysticism includes three broadly defined stages: (1) the gradual integration of the ego under the mastery of the idea of a personal God and according to a program of prayer and asceticism, (2) a transcendent revelation of God to the soul experienced as ecstatic contact or union, frequently with a suspension of the faculties, and (3) "a kind of readjustment of the soul's faculties" by which it regains contact with creatures "under the immediate and perceptible influence of God present and acting in the soul" (Maréchal, *Studies in the Psychology of the Mystics*). It is this final stage, which almost all of the greatest Christian mystics have insisted upon, that belies the usual claim that mysticism is a selfish flight from the world and an avoidance of moral responsibility.

The dying to self. The mystics agree on the necessity of dying to the false self dominated by forgetfulness of God. In order to attain the goal, it is necessary to follow the way of purgation: the soul must be purified of all those feelings, desires, and attitudes that separate it from God. This dying to the self implies the "dark night of the soul" in which God gradually and sometimes painfully purifies the soul to ready it for the divine manifestation.

Christ as the model of the purified soul

Christian mystics have always taken Christ, especially the crucified Christ, as the model for this process. According to the *Theologia Germanica,* "Christ's human nature was so utterly bereft of self, and apart from all creatures, as no man's ever was, and was nothing but a 'house and habitation of God' " (chapter 15). The following of Christ involves a dying to self, a giving up of oneself wholly to God, so that one may be possessed by the divine Love. Such detachment and purgation were frequently expressed in extreme terms that imply the renunciation of all human ties. Paradoxically, those who insist upon the most absolute detachment also emphasize that purifying the self is more a matter of internal attitude than of flight from the world and external penance. In the words of William Law: "The one true way of dying to self wants no cells, monasteries or pilgrimages. It is the way of patience, humility and resignation to God" (*The Spirit of Love,* Part 1).

The practice of meditation and contemplative prayer,

leading to ecstasy, is typical of Christian and other varieties of theistic mysticism. This usually involves a process of introversion in which all images and memories of outer things must be set aside so that the eye of inner vision may be opened and readied for the appearance of God. Introversion leads to ecstasy in which "the mind is ravished into the abyss of divine Light" (Richard of Saint-Victor, *The Four Grades of Violent Love*). Illumination may express itself in actual radiance. Symeon the New Theologian speaks of himself as a young man who saw "a brilliant divine Radiance" filling the room. In the path to union many of the Christian mystics experienced unusual and extraordinary psychic phenomena—visions, locutions, and other altered states of consciousness. The majority of mystics have insisted that such phenomena are secondary to the true essence of mysticism and can even be dangerous. "We must never rely on them or accept them," as John of the Cross said in *The Ascent of Mount Carmel,* 2.11.

The union with God. Christian mystics claim that the soul may be lifted into a union with God so close and so complete that it is in some way merged in the being of God and loses the sense of any separate existence. Jan van Ruysbroeck wrote that in the experience of union "we can nevermore find any distinction between ourselves and God" (*The Sparkling Stone,* chapter 10); and Eckhart speaks of the birth of the Son in the soul in which God "makes me his only-begotten Son without any difference" (German *Sermons,* 6). These strong expressions of a unity of indistinction have seemed dangerous to many, but Eckhart and Ruysbroeck insisted that, properly understood, they were quite orthodox. Bernard of Clairvaux, who insisted that in becoming one spirit with God the human "substance remains though under another form" (*On Loving God,* chapter 10), and John of the Cross, who wrote "the soul seems to be God rather than a soul, and is indeed God by participation" (*The Ascent of Mount Carmel* ii, 5:7), express the more traditional view of loving union.

The readjustment. The goal of the mystic is not simply a transient ecstasy; it is a permanent state of being in which the person's nature is transformed or deified. This state is frequently spoken of as a spiritual marriage that weds God and the soul. This unitive life has two main aspects. First, while the consciousness of self and the world remains, that consciousness is accompanied by a continuous sense of union with God, as Teresa of Ávila clearly shows in discussing the seventh mansion in *The Interior Castle.* Brother Lawrence wrote that while he was at work in his kitchen he possessed God "in as great tranquillity as if I were upon my knees at the Blessed Sacrament" (*The Practice of the Presence of God,* chapter 4). Second, the spiritual marriage is a theopathic state: the soul is felt to be in all things the organ or instrument of God. In the unitive life Mme Guyon says that the soul "no longer lives or works of herself, but God lives, acts and works in her." In this state the mystic is able to engage in manifold activities without losing the grace of union. In the words of Ignatius of Loyola, the mystic is "contemplative in action."

The spiritual marriage

FORMS OF CHRISTIAN MYSTICISM

Christian mysticism has expressed itself in many forms during the last two millennia. Three broad types characterize much of Christian mysticism, though these should not be seen as mutually exclusive. Some mystics tend to emphasize one form over the others, while others make use of all three.

Christ-mysticism. The earliest form of Christian mysticism was the Christ-mysticism of Paul and John. Although Christian mysticism in its traditional expression has centred on aspiration for union with God, Christ-mysticism has always been present in the church. In the Eastern Church emphasis was placed on the divine Light that appeared to the disciples at the Transfiguration, and mystics sought to identify with this light of Christ in his divine glory. Symeon says of a certain mystic that "he possessed Christ wholly. . . . He was, in fact entirely Christ." In the Catholic West, with reference to the founding figure of Augustine, it is evident that it is in and through the one Christ, the union of Head and body that is the church, that humans come to experience God. For Augustine the mystical life is Christ "transforming us into himself" (*Homily on Psalm,* 32.2.2). In the medieval period some of the most profound expressions of Christ-mysticism are found in the women mystics, such as Catherine of Siena and Julian of Norwich. Luis de León spoke of the theopathic life in terms of Christ-mysticism: "The very Spirit of Christ comes and is united with the soul—nay, is infused throughout its being, as though he were soul of its soul indeed."

With Protestants the attempt to return to primitive Christianity has led to strong affirmations of Christ-mysticism. The early Quaker George Keith wrote that Christ is born spiritually in humanity when "his life and spirit are united unto the soul." The chief representative of Christ-mysticism among the early Protestants was Kaspar Schwenckfeld. For him Christ was from all eternity the God-man, and as such he possessed a body of spiritual flesh in which he lived on Earth and which he now possesses in heaven. In his exalted life Christ unites himself inwardly with human souls and imparts to them his own divinity.

Trinitarian mysticism. Pure God-mysticism is rare in Christianity, though not unknown, as Catherine of Genoa shows. Christ as God incarnate is the Word, the second Person of the Trinity, and Christian mysticism has, from an early era, exhibited a strong Trinitarian dimension, though this has been understood in different ways. What ties the diverse forms of Trinitarian mysticism together is the insistence that through Christ the Christian comes to partake of the inner life of the Trinity. The mysticism of Origen, for example, emphasizes the marriage of the Word and the soul within the union of Christ and the church but holds out the promise that through this action souls will be made capable of receiving the Father (*First Principles,* 3.6.9). The mystical thought of Augustine and of such medieval followers as Richard of Saint-Victor, William of Saint-Thierry, and Bonaventure is deeply Trinitarian. Meister Eckhart taught that the soul's indistinction from God meant that it was to be identified with the inner life of the Trinity—that is, with the Father giving birth to the Son, the Son being born, and the Holy Spirit proceeding from both. A similar teaching is found in Ruysbroeck. John of the Cross wrote of mystical union that "it would not be a true and total transformation if the soul were not transformed into the three Persons of the Most Holy Trinity" (*Spiritual Canticle,* stanza 39.3). Such strong Trinitarian emphasis is rarer, but not absent from Protestant mysticism.

Negative mysticism: God and the Godhead. The most daring forms of Christian mysticism have emphasized the absolute unknowability of God. They suggest that true contact with the transcendent involves going beyond all that we speak of as God—even the Trinity—to an inner "God beyond God," a divine Darkness or Desert in which all distinction is lost. This form of "mystical atheism" has seemed suspicious to established religion; its adherents have usually tried to calm the suspicions of the orthodox by an insistence on the necessity, though incompleteness, of the affirmative ways to God. The main exponent of this teaching in the early centuries was the Pseudo-Dionysius, who distinguished "the super-essential Godhead" from all positive terms ascribed to God, even the Trinity (*The Divine Names,* chapter 13). In the West this tradition is first found in Erigena and is especially evident in the Rhineland school. According to Eckhart, even being and goodness are "garments" or "veils" under which God is hidden. In inviting his hearers to "break through" to the hidden Godhead, he daringly exclaimed, "let us pray to God that we may be free of 'God,' and that we may apprehend and rejoice in that everlasting truth in which the highest angel and the fly and the soul are equal" (German *Sermons,* 52). The notion of the hidden Godhead was renewed in the teaching of Jakob Böhme, who spoke of it as the *Ungrund*—"the great Mystery," "the Abyss," "the eternal Stillness." He stressed the fact of divine becoming (in a nontemporal sense): God is eternally the dark mystery of which nothing can be said but ever puts on the nature of light, love, and goodness wherein the divine is revealed to human beings.

The unknowability of God

SIGNIFICANCE OF CHRISTIAN MYSTICISM

The study of Christian mysticism presents both the unity of mysticism as an aspect of religion and the diversity of expression that it has received in the history of Christian faith. The mystic claims contact with an order of reality transcending the world of the senses and the ordinary forms of discursive intellectual knowing. Christian mystics affirm that this contact is with God the Trinity and can take place only through the mediation of Christ and the church, whether explicitly or implicitly at work. The claim is all the more significant in that Eastern Orthodox Christians, Roman Catholics, and Protestants are here in agreement.

Without in any way affirming that all mysticism is everywhere one and the same, it can be said that the Christian mystics take their stand with the mystics of other traditions in pointing to "the Beyond that is within." In an age when the claims of established religion are so widely questioned, the witness of the mystics is of particular appeal; but it should be remembered that most mystics have not been rebels against their respective religious confessions. Another great question that confronts the present age is the relation of Christianity to other world religions. If Christianity is to embark upon truly cooperative relations with other religions, it must be deeply imbued with the insight and experience of the mystics. Even if it is to attempt to plumb the depths of its own history, it cannot neglect its mystical dimensions. (S.Sp./B.J.McG.)

Christian myth and legend

Myths and legends number among the most creative and abundant contributions of Christianity to the history of human culture. They inspire artists, dramatists, clerics, and others to contemplate the wondrous effects of Christian salvation on the cosmos and its inhabitants. They conjoin diverse cultural horizons, taking those worldviews bounded by Christian revelation and fusing them creatively with the religious histories that exist prior to and alongside the orthodox Christian world. Even for the less pious and the nonbelievers, the distinctive visions of reality presented in Christian legend or myth and the symbolic actions based upon them have helped to form the fundaments of Western civilization. Pilgrimage to the shrines of legendary saints, to mention but one example, touches economic and political life, military history, visual and musical arts, popular devotion, and the exchange of scientific information. Moreover, the content of the legends and myths themselves has contributed directly to theories about religion, society, politics, art, astronomy, economics, music, and history.

CHARACTERISTICS OF CHRISTIAN MYTH AND LEGEND

An appreciation of the positive role of myth and legend in culture has been long in coming. Christian theology, taking its lead from Greek philosophy, at first denigrated the value of myth. In constructing the Christian canon and in choosing authoritative interpretations of it, the early church suppressed or excluded myth and legend in favour of the genres of philosophy, history, and law. The opinion expressed in the First Letter of Paul to Timothy only echoes the prevalent Hellenistic view of myth: "Have nothing to do with godless and silly myths" (1 Timothy 4:7). In spite of that, a number of important mythical themes remain central to the New Testament—*e.g.*, Christ as the second Adam (Romans 5:12–14), the heavenly spheres (2 Corinthians 12:2–4), and the celestial battle between angels and demons. Still visible, but barely so, in the writings of Paul (Galatians 3:28) is the early Christian theme of the androgyny of Christ and of his spiritually accomplished disciples.

Early exclusion of myth and legend

The Apologists from the 2nd to the 5th centuries used legend and myth. Clement of Alexandria employed them as allegories to make Christian concepts intelligible to Greek converts. But Clement (*e.g.*, in his *Protreptikos* ["Exhortation"]) and other Church Fathers roundly condemned the belief that Greek myths might be autonomous sources of truth. In spite of its ambiguous use of mythic symbols and themes, the history of Christian doctrine testifies to the systematic excision of legendary and mythical elements from Christian orthodoxy. Even folk practices, based on legend, were policed and suppressed. In 692, for example, the Quinisext Council (also known as the Trullan Synod), a precedent-setting episcopal council convoked by the Byzantine emperor Justinian II, prohibited baking bread in the form of the Virgin Mary's placenta, as was the custom on the afterbirth day (that is, the day after Christ's birth). This ambiguous, but ultimately negative, evaluation of Christian myth and legend lingers to this day.

A second cause for the delay in evaluating the positive contributions of myth and legend to religious life is the theories of religion that have flourished since the time of the European Enlightenment. These theories treated myths as infantile projections of the prerational childhood of the human race (projections surpassed by the mature rationalism of the Enlightenment). More intimate knowledge of mythic traditions in Africa, India, Oceania, and the Americas, however, has disclosed the important role myth plays in culture and highlighted the coherence and sophisticated order of myth.

Role of myth in society

Myths narrate the sacred events that unfolded in the first time, the epoch of creative beginnings. In that primordial period supernatural beings brought reality—in part or in whole—into existence. In that sense, myth relates only those things that have really occurred—that is, those realities that have revealed themselves completely. These realities become the foundation of the world, society, and human destiny. Myths manifest the acts and beings that are sacred, that are completely other than the world encountered in day-to-day experience. Myths are always paradoxical because realities that are other than those of this world have nonetheless established it. The intervention of sacred and supernatural beings accounts for the conditions of the world and humanity today. Myth describes the acts and beings whose appearance shaped material existence in all its concrete specificity.

Legends are episodic continuations of mythic narratives, for they describe the effects of primordial events on history—a history revealed through the imagination and one as fabulous as the primordial mysteries that brought that history into being. Legends must describe history in fantastic terms in order to clarify the significance of the powers that underlie it. The repetitiveness and redundancy of legends emphasize the fact that many different legends spring from the same mythic sources—that is, from the same primordial events and creative powers. But variants of legend are reminders that myths and their outcomes are historically conditioned and questioned. Christian legend contends with the question of what the Christian mystery means here and now, in these particular, everyday circumstances. Because of their local frame of reference, legends vary incessantly, and widely different accounts emerge from diverse locales and periods. Favourite legendary themes are the struggles and miraculous adventures of heroes in the faith. Such accounts edify the faith and bolster the courage of the listener.

There is no complete account of Christian legend and myth, nor is there a full outline of the mythic world engendered by the economy of salvation set in motion with the life of Christ and his disciples. Above all, the theologies of rural populations and oral traditions have been slighted in the study of Christian thought. A historical interpretation of the full mythical and legendary expression of Christianity would probably reveal a surprising adherence to tradition even while it uncovered startling reinterpretations of the Christian message over time. Christian myths and legends exuberantly express the truths of Christian existence, viewed as a religious situation in the social and physical world. The mystery of salvation unfolds when the eternal God dramatically enters the created universe in the form of an incarnate, mortal creature. "Like us in all things but sin," God's presence among human beings is mysterious, and the meaning of this mystery risks remaining hidden and undeciphered. Legends and myths spell out the effects of these salvific secrets not only for human individuals but also for all realms of reality—animal, vegetal, astral, material, corporeal, social, and intellectual. By quickening the listeners' religious awareness of the salvation unfold-

ing around them, the symbols of legend and myth often aimed to further the redemptive effects of the mysteries and wonders they describe. (L.E.S.)

HISTORY OF CHRISTIAN MYTH AND LEGEND

The early church. Early Christianity appropriated mythological motifs and genres from the Greek and Middle Eastern cultures that dominated the Hellenistic Age (*c.* 300 BC–*c.* AD 300). Among them was the miraculous birth of a deity; the virgin birth of a god or goddess was a theme common in the mythology of the Hellenistic world. Aphrodite (Venus), the goddess of sexual love, for example, emerged from sea foam. Athena sprang, in full battle array, from the head of Zeus, her father. The legend of the virgin birth of Alexander the Great (4th century BC) from his mother, Olympias, whose reputation was not that of a virgin, demonstrated Alexander's divinity. Mithra, the Iranian god of light and of sacred contracts, is described as a divine child of radiant heavenly beams. Mithra was born from the rock of a cave, the birth witnessed by shepherds on a day (December 25) that was later claimed by Christians as the Nativity of Christ.

Influence of Judaism

Hellenistic Judaism had already reinterpreted many Gentile motifs and set them within a biblical context. From Greek and Jewish sources Christians adopted and adapted some favourite mythical themes: the creation of the world, the end of the paradisal condition and the fall of humankind, the assumption of human form by a god, the saved saviour, the cataclysm at the end of time, and the final judgment. Christians reframed these motifs within their new images of history and their doctrines concerning the nature of God, sin, and redemption. As it spread beyond Palestine and the Hellenistic world over the course of time, Christianity continued to develop mythical themes important to the religious consciousness of converted peoples.

The ages of the world. One fascinating mythical theme in the New Testament is that time consists of a series of ages. Each age of the world (or kingdom) is dominated by a powerful force or figure. This motif exists throughout the globe with a range of specific cultural meanings. In the 8th century BC in Greece, the poet Hesiod described the ages of the world as four in number and symbolized by gold, silver, bronze, and iron, each age successively declining in morality. In India the four *yuga*s (Sanskrit: "world ages"), symbolized by the four throws of a dice game, also are viewed as descending—though in repetitive cycles—from perfection to moral chaos. Other original schematizations of this theme can be found in the mythologies of Chinese, Polynesian, and American Indian cultures.

By the time the New Testament was written, Jewish apocalyptic writings (symbolic or cryptographic literature portraying God's dramatic intervention in history and catastrophic dramas at the end of a cosmic epoch) had already produced theories of history that reworked Indo-Iranian notions about the ages of the world. Iranian concepts most influenced Christian views of time, history, and ultimate human destiny. The prophet Zoroaster (*c.* 7th century BC) and his followers in Iran taught a doctrine of the four ages of the world in which each age was a different phase in the struggle between two kinds of powers—light and darkness, goodness and evil, spirit and matter, infinity and finitude, health and sickness, time and eternity. The forces of good and evil battled for the allegiance and the souls of human beings. In the last days a promised saviour (Saoshyant) would pronounce final judgment and announce the coming of a new world without end in which truth, immortality, and righteousness would have everlasting reign.

Stages of the Christian apocalypse

Drawing on Jewish apocalyptic literature (exemplified in the Book of Daniel), early Christian apocalypse (exemplified in the Book of Revelation) elaborated the theme of the ages of the world as a series of historical periods in which good struggles against evil: (1) from the creation of the world and of humanity to the Fall into sin and out of Eden; (2) from the Fall to the first coming of Christ; (3) from the first to the second advent of Christ, which includes the 1,000-year reign of Christ and his saints and the Last Judgment; and (4) the creation of a new heaven and a new earth in which those who have chosen the good (*i.e.*, Christ) will live in eternity. Within this framework of the mythical history of the ages of the world, Christian apocalyptic re-envisions a number of themes important to Jewish apocalypticism: the Son of man and the great tribulation prior to the judgment of the world; the battle between Christ and the Antichrist, a false messiah or "great liar" who denies that Jesus is the Christ and who pitches the world into moral confusion and physical chaos; and the ultimate triumph over Satan, who appears as a dragon but who no longer deceives the nations of the world.

The theme of the several ages of the world has a long and fruitful life in Christian thought and undergirds many Western concepts of progress toward a better state of existence or of decline toward extinction. Montanus, a heretical Christian prophet of the early 2nd century, claimed that history progressed from an age of the Father to an age of the Son to an age of the Holy Spirit, of whom Montanus was the manifestation. One could fruitfully explore the degree to which such apocalyptic myths underlie not only the religious theories of a multistage history, as propagated by Martin Luther, the early Jesuits, Christopher Columbus (in his *Book of Prophecies*), and Giambattista Vico, but also the more secular philosophies of history developed by Gotthold Ephraim Lessing, the comte de Saint-Simon, Auguste Comte, Johann Gottlieb Fichte, G.W.F. Hegel, Friedrich Schelling, and Karl Marx.

Messianic secrets and the mysteries of salvation. New Testament references to the "mysteries of the kingdom of heaven" (for example, Matthew 13:11; Mark 4:11; Luke 8:10) generated myth and legend. The New Testament emphasis on secrecy and on the mysteries of salvation became fertile ground for the exfoliations of myth and legend. Things hidden from the beginning of the world now blossomed in the signs of the new messianic age. These truths, now come to light, should be proclaimed to the whole world. Through myth and legend Christians transmitted and explored, with the full force of the imagination, the wonders revealed in Christ and the secrets of his salvation.

Esoteric traditions, especially those based on apocalypses and apocrypha (such as the *Apocalypse of Peter, Gospel of Thomas, Secret Gospel of Mark,* and *Gospel of Philip*) preserve some legends and myths descending from the early Christian centres of Edessa, Alexandria, and Asia Minor.

The childhood of Jesus

The *First Gospel of the Infancy of Jesus* (known also as the Arabic Infancy Gospel) recounts that, one day, Jesus and his playmates were playing on a rooftop and one fell down and died. The other playmates ran away, leaving Jesus accused of pushing the dead boy. Jesus, however, went to the dead boy and asked, "Zeinunus, Zeinunus, who threw you down from the housetop?" The dead boy answered that Jesus had not done it and named another (*I Infancy* 19:4–11). This and other such narratives describe the "hidden life" of Jesus in the 30 years before his public ministry began. The *Acts of Paul and Thecla* narrates the story of a friend of Paul who was thrown to the lions—one of which defended her in a manner similar to that of the lion in the story of Androcles, a well-known legend. Other exemplary legends appear in the *Acts of the Martyrs* and other histories. After Christian theologians defined orthodoxies in terms of Greek philosophy or Roman juridical code, these mythic themes appeared clumsy or tasteless and, in retrospect, heterodox or even heretical.

Groups of Gnostics and heretics who based their ideas on alternative mythologies of the economy of Christian salvation furnished exotic Christian myths, legends, and practices. In the 2nd and 3rd centuries these groups often subscribed to theories of dualism: the world of matter created by an evil god (of the Book of Genesis) and the realm of the spirit created by a good god (revealed in the New Testament) were irreconcilably pitted against one another. The many Gnostic sects—among them the Valentinians, Basilidians, Ophites, and Simonians—developed a variety of myths. Valentinus lived in Rome and Alexandria in the mid-2nd century. Valentinian myths describe how the pleroma (spiritual realm) that existed in the beginning was disrupted by a Fall. The Creator God of Genesis, aborted from the primordial world, became a Demiurge and cre-

ated the material universe. He deliberately created two kinds of human being and animated them with his breath: the hylics and the psychics. Unknown to the Demiurge, however, certain remnants of pleromic wisdom contained in his breath lodged as spiritual particles in matter and produced a third group of beings called pneumatics. The God of Genesis now tries to prevent Gnostics from discovering their past origins, present powers, and future destinies. Gnostics (the pneumatics) contain within themselves divine sparks expelled from the pleroma. Christ was sent from the pleroma to teach Gnostics the saving knowledge (gnosis) of their true identities and was crucified when the Demiurge of Genesis discovered that Christ (the male partner of the feminine Holy Spirit) was in Jesus. After Christ returned to the pleroma, the Holy Spirit descended.

Myths of the Ophites

The Ophites (from the Greek word *ophis,* "serpent") reinterpreted the mythological theme of the Fall of Man in Genesis. According to the Ophite view, the serpent of the Garden of Eden wanted Adam and Eve, the first man and woman, to eat from the tree of knowledge (*gnosis*) so that they would know their true identities and "be like God" (Genesis 3:5). The serpent, thus, is interpreted as a messenger of the spiritual god, and the one who wanted to prevent Adam and Eve from eating the fruit of the tree of knowledge is viewed as the Demiurge. In their rejection of the God of the Old Testament, who gave the Ten Commandments, the Ophites flaunted their sexual freedom from the law and conventionality by extreme sexual license, a trait common to other Gnostic groups as well.

The Phibionites in Alexandria were a Gnostic sect described by Epiphanius. They gathered at banquets that became ecstatic orgies. Married couples changed partners for dramatic sexual performances. Sperm and menstrual blood were gathered and offered as a gift to God before being consumed as the Body and Blood of Christ. By such erotic communions they sought to regather the elements of the world-soul (*psyche*) from the material forms into which it had been dispersed through a cosmic tragedy at the beginning of time. The regathering amounted to salvation, for all things would be gathered up into the one glorious body of Christ. (L.F./L.E.S.)

The Magi and the Child of Wondrous Light. The legend of the Magi-Kings was embellished in apocryphal books and Christian folklore. The *Protogospel of James* and the *Chronicle of Zuqnin* describe the birth of the Saviour. Like the god Mithra, the divine child is consubstantial with celestial light and was born in a mountain cave on December 25. Such imagery of the Nativity of Christ and the symbolism of the royal visitors may originally have descended from Iranian accounts of the birth of the cosmic saviour, for the accounts seem to owe a great deal to Iranian theologies of light. But the themes have been recast in Christian terms. The *Opus imperfectum in Matthaeum* relates that 12 Magi-Kings lived near the Mountain of Victories, which they climbed every year in the hope of finding the messiah in a cave on the mountaintop. Each year they entered the cave and prayed for three days, waiting for the promised star to appear. Adam had revealed this location and the secret promises to his son Seth. Seth transmitted the mysteries to his sons, who passed the information from generation to generation. Eventually the Magi, sons of kings, entered the cave to find a star of unspeakable brightness, glowing more than many suns together. The star and its bright light led to, or became, the Holy Child, the son of the Light, who redeems the world.

Relics and saints. The cult of saints gained momentum from the 4th to the 6th century. The bones of martyrs gave stirring evidence of God's power at work in the world, producing miracles and spectacles of the effectiveness of faith. The martyrs had imitated Christ even unto death, and the remains of their holy bodies served as contacts between earth and heaven. On the model of Christ's Incarnation, the bones of martyred saints embodied God's salvific power and thus became the centre of active cults. Relics were installed in special churches called martyria or in basilicas. The tombs of martyrs, on the margins of cities and towns, attracted pilgrims and processions. Legends described the prodigious virtues of martyrs and saints, as well as the dreams or visions that revealed the resting places of still more powerful relics. Each discovery (*inventio*) promised new and effective signs of divine redemption. Returning from distant places, especially Rome, pilgrims brought relics to their home churches. Thus, during the 8th century, bones and other relics were moved from southern Europe to the north and west. During the Middle Ages especially, deities and cultural heroes became elements of Christian hagiography.

The True Cross and the World Tree

Of all discovered relics the most impressive was the True Cross, found in September 335 (or in 326, according to other accounts). Prompted by a dream, Helena, mother of the emperor Constantine, located the place where the Cross lay buried and had the wood unearthed. The power of the Cross, the history of the wood, and the story of its discovery became legendary. In Christian myth this relic of Christ's death dated back to the mortal origins of humanity. Innumerable cures attested to the authenticity of the Cross.

Through the symbolism of the Cross early Christian imagery perpetuated, and at the same time transformed, the myths of the World Tree. The sacred drama of Christ's birth, death, and Resurrection participates in the rejuvenating rhythms of the fecund cosmos. Early Christians identified the Cross of Christ as the World Tree, which stood at the centre of cosmic space and stretched from earth to heaven. The Cross was fashioned of wood from the Tree of Good and Evil, which grew in the Garden of Eden. Below the tree lies Adam's buried skull, baptized in Christ's blood. The bloodied Cross-Tree gives forth the oil, wheat, grapes, and herbs used to prepare the materials administered in the sacraments that revitalize a fallen world. The Italian Renaissance painter Piero della Francesca later depicted the myth of the True Cross in his frescoes in Arezzo, Italy. They portray the death of Adam, fallen at the foot of the Tree that provides wood for the crucifix on which Jesus is slain. But the wood of the Cross becomes the instrument of salvation and the holiest matter in Christendom. Fabulous accounts and fantastic historical episodes surround the Cross.

Another 4th-century event, the discovery of Christ's tomb, the Holy Sepulchre in Jerusalem, also became a highlight of Christian legend. Like the body of the Saviour, the tomb is a "holy of holies." Its discovery was tantamount to the Resurrection, for its reemergence into the light of day was seen as a restoration of life where before only darkness reigned. The Cross and the tomb were woven together in legend. The desire to regain possession of the True Cross and the Holy Sepulchre eventually fueled the territorial expansion of Christian empires and spurred Christian knights to crusade. (L.E.S.)

The Middle Ages. As Christianity expanded from the cultural milieu of the Mediterranean area to the north and east, the various converted tribes and peoples did not, understandably, forget their own religious heritages. Just as attributes of the Roman god of war, Mars, had been transferred to Michael, the archangel who is the leader of the heavenly hosts, in the early centuries of the church,

so also the attributes of the gods of the Germanic, Baltic, Slavic, and other peoples were transferred to angels and saints during the Middle Ages. For example, St. George, who rescued a maiden after slaying a dragon, became the patron saint of England and one of the most popular saints among the Balts (among whom St. George replaced the god Kalvis, the heavenly smith and dragon slayer).

Prester John and the Holy Grail

Nor were saints the only legendary figures important to Christendom. Prester (Presbyter) John, a fabled Christian priest-king of the Orient, became so believable a figure in the Middle Ages that Pope Alexander III dispatched a letter to him in 1177. Similarly, the legend of the wandering Jew, who had taunted Jesus on his way to be crucified, was popular in the 13th century and again, from the 17th century on, in the stories about the wanderer Ahasuerus.

For the Christian medieval world the Holy Grail (the chalice used by Jesus at the Last Supper) symbolized the truth and knowledge needed to achieve the experience of salvation. Led in search of the Grail by divine grace, the naive hero Perceval inquired directly about the Grail, a question other knights had failed to ask. His simplistic question, put to the ailing Fisher King, revitalized not only the royal body but the entire drooping cosmos. The human condition is rejuvenated by the graceful quest for the truth of salvation. Perceval was superseded by Galahad as the winner of the Holy Grail in later variations, Galahad being viewed as a descendant of Joseph of Arimathea (the member of the Jerusalem council in whose tomb the body of Jesus was laid), who was believed to have gone to Glastonbury, Eng., with the Holy Grail. (L.F./L.E.S.)

Probably under the influence of Bogomil and Cathar heretical tendencies toward dualism, apocryphal books of Christian legends (such as *The Wood of the Cross, Gospel of Nicodemus, How Christ Became a Priest, Adam and Eve,* and *Interrogatio Iohannis*) circulated in both eastern and western Europe. They usually stressed the role of Satan as co-creator of the world or as a being whose fall is responsible for the evil world that exists. The devil plays a major role in legend, and his activity usually exhausts the creative energies of the good God, who falls into passivity.

A number of Christian myths, legends, and works of art were aimed at awakening religious capacities, turning the viewer or listener against repulsive forms of evil, and hastening the effects of the salvation achieved in Christ. Nowhere is this better illustrated than in the bestiaries, fables, and cosmic dramas sculpted into Romanesque cathedrals. Christ, the glorious King, and his saintly cohorts confront armies of monsters and demons. Together the two sides show forth the full spectrum of the imaginary world of Christian legend and myth of the day.

Christ being tempted by a devil, "Temptation of Christ," engraving by Master LCZ (Lorenz Katzheimer), *c.* 1492.

Christian legends and myths were also woven into long-lived literary creations: the late medieval chansons de geste yielded to the epic tales, lyric poetry, and songs that conducted audiences into an enchanted symbolic world that paralleled their mundane one. Such are the enigmatic poems of the 12th-century Court of Love and the literature patronized by Eleanor of Aquitaine and her daughter, Marie, countess of Champagne. Similarly the troubadours of 12th-century Provence creatively refashioned, in Christian terms, the inspirations they received from the Arabic poetry of Spain and the influences of Celtic, Gnostic, and Oriental themes in circulation at the time. These tendencies toward the fantastic in Christian expression reached their literary peak in the works of Dante (1265–1321), whose *Divine Comedy* depicts the terrifying and attractive visions of Paradise, Purgatory, and Hell in such a way as to quicken the ultimate powers of the imagination and thereby draw the reader toward the effective images of the mystery of their own salvation.

King Arthur and the Round Table

In the place of Charlemagne, a favourite hero of the old chansons de geste, the legendary cycles of the 12th century spawned a new generation of romantic heroes—King Arthur and the knights of his Round Table. Marie, countess of Champagne, sponsored Chrétien de Troyes, the poet who composed five long romances that became the mythic foundation for chivalry. These cycles interweave Christian, Muslim, and Gnostic elements into a singular cosmic vision. Suffering ordeals during their adventures, the knights of the Arthurian cycle (Arthur, the Fisher King, Perceval, and Lancelot) journey through the Wasteland on their heroic quests for the Holy Grail and for the cure that will revitalize king and cosmos. Wolfram von Eschenbach offers the most coherent mythology of the Grail in his *Parzival,* a refinement of Christian legends that draws on the worlds visited by the crusaders and by Italian merchants—Syria, Persia, India, and China. At the conclusion of many of these cycles, the Holy Grail, often in the image of the chalice of salvation in Christ, is transported to a fabulous mythical location in the Orient.

Joachim of Fiore's universal history

The 12th century also witnessed the rise of a new mythology of Christian history. Joachim of Fiore (1130/35–1201/02) was an abbot of the Calabrian monastery of Fiore and was well-known in the Christian world of his day. On the vigil of Easter and on Pentecost Sunday, God infused him with special knowledge, which enabled him to decode history as a series of divine signs. According to Joachim, universal history has three stages, each age (*status*) corresponding to a person of the Holy Trinity. The first age, presided over by God the Father, was ruled by married men and propelled by their labour. Jesus Christ presided over the age of the New Testament, an epoch ruled by the clergy and driven forward by the power of science and discipline. The two testamental periods featured the two kinds of people chosen in each, the Jews and the Gentiles. Joachim fascinated the faithful of his day with a prediction that the second age, the age of the New Testament presided over by Jesus Christ, would end in 1260. Then would dawn a new epoch, the third age, presided over by the Holy Spirit, guided by monks and fueled by their contemplation. It was to be an epoch of total love, joy, and freedom. But three and one-half years of cataclysm ruled by the Antichrist would precede entrance to this bliss.

Joachim promised that God's mysterious saving power would burst fully into history in the immediate future and would change forever the fundamental structures of the cosmos as well as the social and ecclesiastical world. Joachim's new vision of history generated critiques of the 13th-century church and society. His doctrine of the Trinity was condemned at the fourth Lateran Council in 1215. In 1255 Pope Alexander IV suppressed a collection of his written works, and in 1263 the regional Council of Arles condemned many of Joachim's most stirring ideas.

His notions of an impending third epoch, in which history would come to complete fulfillment, lived on.

Renaissance magic and science. Christian legend and myth also found fertile ground in the practices of alchemy. Through the perfection of metals the alchemists sought their own perfection and, indeed, the salvation of all matter. Through the mysterious and great work (magnum opus) of alchemy the alchemist dissolved, then fused, his own physical matter and spirit with the prime matter of the universe. These initiatory experiences of reduction into prime matter made possible the re-creation of individual and cosmos as a single, pure element. Even the philosopher's stone or elixir was reinterpreted so that Christ appeared as the perfect matter produced by the alchemical process—that is, Christ was the stone of all wisdom and knowledge. In the alchemist's spiritual forge, the Stone reemerged from the Matrix, the crucible containing the so-called Bath of Mary, whose amniotic fluids dissolved all impurities. This dissolution prepared one for rebirth as a perfect being. All matter was redeemed by immersion in the fluids of the womb where Jesus took flesh. Mystical union with Christ's death and physical regression to that same uterus where God became matter empowered the Christian alchemist to effect a new fusion of redeemed realities, freed of all impure dross. Scientists secretly continued the alchemical tradition. Among them numbered the foremost pioneers of modern physics and chemistry: Robert Fludd, Robert Boyle, and Sir Isaac Newton.

Legends of alchemy

Legends also found their place in the growing science of astronomy. In the Middle Ages it was learned that conjunctions of planets occur every 20 years on a minor scale and every 960 years on a major scale. This theory, described in the *Liber magnarum coniunctionum,* was advocated by Albumazar (787–886), a disciple of al-Kindī (?–*c.* 870), a Muslim philosopher who assimilated Greek philosophy to Islām. Roger Bacon used this theory to work out the chronology of great personalities in history and to map the chronological relationship of true prophets (Alexander the Great, Jesus Christ, Mani, and Muḥammad), one for every 320 years. Based on observations of a supernova in 1604, Johannes Kepler calculated the "true date" of the birth of Jesus. These calculations revitalized an interest in the legendary Magi, who had followed the great star. Kepler believed that the conjunctions were unnatural events brought about by the miraculous acts of God, who had decided to lodge the birth of his son between the significant zodiacal signs of the Fish (Pisces) and the Ram (Aries).

Rosicrucian announcements of the imminent coming of a new world also propagated the theory that great celestial conjunctions appeared at the births of prophets and saviours. The scientific achievements of Kepler became a foundation for the new secret order reputedly founded by Christian Rosenkreuz, for it confirmed their hopes. The editors of Rosicrucian publications dated the death of their founder to 1484 and fixed the time of the discovery of his tomb as 1604 in order to coordinate the events with the last two great conjunctions of stars.

Christian practice in the modern world. The 20th century continues to generate important Christian myths and legend-based practices, including pilgrimages made on Marian feast days to holy wells and fairy rings outside the Irish town of Sneem and devotions at the tomb of Christ in Japan, where, according to local legend, Christ ended the long life of missionary travels he began after his mock death in Jerusalem. These acts and the legendary explanations that accompany them detail the impact of Christian salvation on present-day reality. In all the cultures where Christianity has been propagated, myth and legend express the fulfillment of the religious desires and hopes that constituted the religious traditions before contact with Christian revelation. The following examples suggest their variety and vitality.

Healing of the sick

The healing of sickness is, as it was in the time of the New Testament, a sign of the coming of the Kingdom of Christ in its fullness. In Africa, for example, many so-called Independent Churches creatively reinterpret disease and rites of cure along Christian lines. In Douala, Cameroon, during the 1980s, two healing prophets named Mallah and Marie-Lumière divided their disciples, whom they called the "sick ones of the Father," into groups named for the important categories of illness described in the Gospels: the Blind, the Halt, the Lame, the Deaf, the Epileptic, the Dumb, and the Paralyzed. The disciples evidenced none of these physical symptoms, but they were asked to identify deep within themselves with the affliction described in the Gospel, so that salvation might touch them in their inner being. By becoming sick, they could be healed and thus join the elect. In lengthy sermons the healing prophets reimagined traditional African religious imagery and refashioned it in the light of Christian belief. The experience of their peculiar mystical disorders afforded a basis for social regrouping and for rethinking the past and present.

The Christian expression of sacred music and trance is often grounded in legend or myth. In Brazil, for example, Macumba, Candomblé, and other Afro-Brazilian cults have roots sunk deep into the religions of African slaves transplanted to the New World. Afro-Brazilian rites often centre on possession by a supernatural being, called an *orixá.* The innumerable *orixás* are ranked in hierarchies modeled on the pantheons of the Yoruba people of West Africa, among others. In Brazil (and in much of Afro-American religious life of the Americas), each *orixá* is identified with a specific Christian saint. In the Umbanda cult of Brazil, altars hold small plaster images of the Christian saints associated with the *orixás.* Each one of the saints presides over a domain of human activity or over a disease, social group, geographic area, or craft. For example, Omolú, the god of smallpox, is identified with St. Lazarus, whose body, in Christian legend, is pocked with sores and who heals diseases of the skin. Oxossi, the Yoruba god of hunting, is associated with the bellicose St. George or St. Michael, the slayers of dragons and other demonic monsters. Yansan, who ate the "magic" of her husband and now spits up lightning, is associated with St. Barbara, whose father was struck by lightning when he tried to force her to give up her Christian faith. In the worship site each *orixá* has its own stone, which is peculiarly shaped, coloured, or textured; arranged in a distinctive position on the altar; and identified as the Cross of Christ. A single saint may be identified with several *orixás* or vice-versa. Regions vary the saintly identifications and some designations shift over time. Each *orixá* has its own musical rhythms and sounds. When called by drums, dance, and music, the supernatural being may take over the possessed medium, reveal valued information, and carry out effective symbolic acts on behalf of the community.

The saints of Umbanda

European communities continue to be fascinated with the rigorous asceticism of St. Anthony of Egypt, who repulsed wild beasts, reptiles, and other assaults and remained steadfast in the faith. He is considered the patron of domestic animals, and in many parts of Italy, the drama of the feast of St. Anthony, historically associated with the winter solstice, rivals any other feast day of the Christian calendar. To celebrate that festival in Fara Filiorum Petri, a town in the Abruzzi region of Italy, the townspeople ignite enormous bonfires on the night of January 16. Each of the 12 outlying hamlets brings into the main town's square a bundle (*farchia*) of long poles. Set on end, the bundles are lashed together to form a single tall mass, an act that commemorates the historical union of the mountain settlements as one bonded community. Then the bundles of *farchie,* 15 or more feet high, are set ablaze. The fire cleanses the community and holds at bay the evil forces of sickness and death. As the fire dies down, young men jump through the purifying flames. Spectators carry remnants of the blessed fire back to their homes, spreading the ashes in their stalls and on their fields.

The feast of St. Anthony

The birth of Christ is still a focus for traditions of legends and myths that maintain their autonomous existence outside of ecclesiastical institutions. In rural Romania, for instance, on Christmas Eve groups of young carolers (*colindatori*) proceed from house to house in the village, singing and collecting gifts of food. Often these carolers impersonate the saints, especially John, Peter, George, and Nicholas. The words of their songs (*colinde*) describe legendary heroes who carry the sun and wear the moon

on their clothes. They live in paradisal worlds and subdue monstrous animals in order to leave the world free from harm and ready to renew itself in the fertile acts of spring.

The symbolic reenactments of legend often experiment with alternative social orders and criticize or reverse existing divisions of labour and prestige. In Sicilian-American communities of Texas, Louisiana, California, and elsewhere, the female head of the household dedicates and displays an altar to St. Joseph and thus fulfills a promise made in a moment of need. Normally, in Roman Catholicism, a priest who is a celibate male presides at the liturgy and at devotional services. In this case, however, a woman presides, together with other women who assist her. She prepares fruit, hard-boiled eggs, cakes, fig-filled pastries, pies, and special breads and uses them to decorate a series of tiers stretching from floor to ceiling. She also arranges on this festival altar the figurines of saints, the Virgin Mary, and the Sacred Heart of Jesus. The construction of this panorama of fruitfulness takes nine days, a period that constitutes a ritual novena of prayer and devout action. Representatives who act in the accompanying ceremony play the roles of the Holy Family and other saints important to the altar display. Re-creating the Holy Family's search for room in a Bethlehem inn on the night of the Nativity, the ritual drama builds toward the moment when the altar-giver opens her home to Joseph and Mary. As Mother Mary prepares to give birth to Jesus, the hostess readies her home, heart, and community so that they may become fit dwelling places for the sacred being. The presiding women play the roles of Magi-Kings bearing gifts of food and hospitality to the Holy Family and their entourage, which includes most of the neighbouring community. A single family can host from 500 to 1,000 people in the feast that terminates the celebration.

Sometimes the new Christian mythologies function as counter-theologies or theologies of resistance to the impositions of Christian culture. They criticize the Christian missionary enterprise even while they embrace aspects of the new religion. For instance, biblical and Christian themes now occupy a large part of the mythology of the Makiritare Indians in the upper Orinoco River region of Venezuela. For them, Wanadi is the Supreme Being of great light and, although one being, he exists in three distinct persons (*damodede,* "spirit-doubles"). Over the course of creation and human history, Wanadi has sent his three incarnations to earth in order to create human beings and redeem them from the darkness into which they have fallen. In the end, Wanadi, the god incarnate who comes to save humankind, is crucified by mythical monsters called Fañuru (from the Spanish *españoles:* "Spaniards"), at the instigation of an evil being called Fadre (from the Spanish *padre:* "father" or "priest"). To all appearances, Wanadi was slain by the Fañurus, but, in fact, he cut his own insides out and allowed his inner spirit (*akato*) to dance free of his dead, cast-off body. Before Wanadi's spirit ascends into heaven, he gathers his 12 disciples about him and promises that he will return in a new and glorious body to destroy the evil world and create a new earth.

Unlike the orthodox canon of Christian scripture, which was inscribed and closed in the first centuries, authentic Christian myth and legend have arisen anew in all the centuries of the Christian Era. The course of Christian myth and legend can be traced through the whole of Christian history. It offers a record of the spread of Christianity—through the Mediterranean, eastern and western Europe, Asia, Africa, Oceania, and the Americas—and highlights the diversity of cultures brought into contact with the Christian message of salvation. The diverse religious hopes, heroes, and rites of these cultures continue to shape reinterpretations of the life of Christ and his saintly followers.

Legend and myth constitute a record of critical reflection on Christian reality in all its dimensions—social, political, economic, doctrinal, and scriptural. No social class or geographic region can lay exclusive claim to Christian myth and legend; they fill the stanzas of royally sponsored poets, the visions of utopian philosophers, and the folklore of rural populations. Indeed, many ideas widely held about the workings of salvation (especially regarding the saints, angels, the devil, and the powers of nature) find their origin in legendary episodes rather than biblical text. Through myth and legend, diverse local communities across the globe have creatively absorbed into their rich religious histories the message of Christian salvation and, through the same fabulous means, they have evaluated the impact of Christian temporal power on their world.

(L.E.S.)

THE CHRISTIAN COMMUNITY AND THE WORLD

The relationships of Christianity

From the perspectives of history and sociology, the Christian community has been related to the world in diverse and even paradoxical ways. This is reflected not only in changes in this relationship over time but also in simultaneously expressed alternatives ranging from withdrawal from and rejection of the world to theocratic triumphalism. For example, early Christians so consistently rejected imperial deities that they were known as radical atheists, while later Christians so embraced European monarchies that they were known as reactionary theists. Radical medieval Franciscans proclaimed that true Christians should divest themselves of money at the same time that the papacy expended great sums to manipulate the political landscape of Europe. Another classic example of this paradoxical relationship is the early monastic withdrawal from the world that at the same time preserved and transmitted classical culture and learning to medieval Europe. In the modern period some Christian communities regard secularization as a fall from true Christianity; others view it as a legitimate consequence of a desacralization of the world initiated by Christ.

The Christian community is always part of the world in which it exists. Thus, the church has served the typical religious function of legitimating social systems and values and of creating structures of meaning, plausibility, and compensation for society as it faces loss and death. The Christian community has sometimes exercised this religious function in collusion with tribalistic nationalisms (*e.g.,* the "German Christians" and Nazism) by disregarding traditional church tenets. When the Christian community has held to its teachings, however, it has opposed such social systems and values (*e.g.,* the stance of the Confessing Church of Germany against Nazism). Given the inherent fragility of human culture and society, religion in general and the Christian community in particular frequently are conservative forces.

However, the Christian community is not always a conservative force. Its ability to criticize the world was bitterly acknowledged by those Romans who attributed the fall of their empire to Christian undermining of their "civil religion." Contemporary black theology and Latin-American liberation theology share the conviction that God takes the side of the oppressed against the world's injustices. From the perspective of theology or faith, the criticism of the world of which the Christian community itself is a part is the exercise of its commitment to Jesus Christ. For the Christian community, the death and Resurrection of Jesus call into question all structures, systems, and values of the world that claim ultimacy.

The relationship of the Christian community to the world may be seen differently depending upon one's historical, sociological, and theological perspectives because the Christian community is both a creation in the world and an influence upon it. This complexity led the American theologian H. Richard Niebuhr to comment in *Christ and Culture* (1956) that "the many-sided debate about the relations of Christianity and civilization . . . is as confused as it is many-sided."

Church, sect, and mystical movement

An influential effort to reduce this confusion to manageable and meaningful patterns was articulated by the German scholar Ernst Troeltsch. He organized the complex relationships of the Christian community to the world into three ideal types of religious social organization: church, sect, and mystical movement. The church is described as a conservative institution that affirms the world and mediates salvation through clergy and sacraments. It is also characterized by inclusivity and continuity, signified by its adherence to infant baptism and historical creeds, doctrines, liturgies, and forms of organization. The objective-institutional character of the church increases as it relinquishes its commitment to eschatological perfection in order to create the *corpus Christianum,* the Christian commonwealth or society. This development stimulates opposition from those who understand the Gospel in terms of personal commitment and detachment from the world. The opposition develops into sects, which are comparatively small groups that strive for subjective, unmediated salvation and that are related indifferently or antagonistically to the world. The exclusivity and historical discontinuity of the sect is signified by its adherence to believers' baptism and efforts to imitate what it believes is the New Testament community. Mystical movements are the expression of a radical religious individualism that strives to interiorize and live out the personal example of Jesus. They are not interested in creating a community but strive toward universal tolerance, a fellowship of spiritual religion beyond creeds and dogmas. The Methodist Church exemplifies the dynamic of these types. The Methodist movement began as a sectarian protest against the worldliness of the Church of England; its success stimulated it to become a church, which in turn spawned various sectarian protests, including charismatic communities.

Niebuhr further developed Troeltsch's efforts by distinguishing five repetitive types of the Christian community's relations to the world. Niebuhr's types are: Christ against culture, Christ of culture, Christ above culture, Christ and culture in paradox, and Christ the transformer of culture. The first two are expressions of opposition to and endorsement of the world, while the last three share a concern to mediate in distinctive ways the opposition between the first two.

Opposition to the world is exemplified by Tertullian's question, "What has Athens to do with Jerusalem?" This sharp opposition to the world was expressed in the biblical disjunction between the children of God and the children of the world and between "the light" and "the darkness" (1 John 2:15, 4:4–5; Revelation); and it has continued to find personal exponents, such as Leo Tolstoy, and communal expressions, such as the Hutterites.

Endorsement of the world emerged in the 4th century with the imperial legal recognition of Christianity by the Roman emperor Constantine. Although frequently associated with the medieval efforts to construct a Christian commonwealth, this type is present wherever national, social, political, and economic programs are "baptized" as Christian. Thus, its historical expressions may be as diverse as the Jeffersonian United States and Hitlerian Germany.

The other three types that Niebuhr proposed are variations on the theme of mediation between rejection and uncritical endorsement of the world. The "Christ above culture" type sees a continuity between the world and faith. This was probably best expressed by Thomas Aquinas' conviction that grace or the supernatural does not destroy nature but completes it. The "Christ and culture in paradox" type views the Christian community's relationship to the world in terms of a permanent and dynamic tension in which the Kingdom of God is not of this world and yet is to be proclaimed in it. A well-known expression of this position is Martin Luther's law–gospel dialectic, distinguishing how the Christian community is to live in the world as both sinful and righteous at the same time. The conviction that the world may be transformed and regenerated by Christianity ("Christ the transformer of culture") has been attributed to expressions that have theocratic tendencies, such as those of Augustine and John Calvin.

Efforts by scholars such as Troeltsch and Niebuhr to provide typical patterns of Christian relations to the world enable appreciation of the multiformity of these relationships without being overwhelmed by historical data. These models relieve the illusion that the Christian community has ever been monolithic, homogeneous, or static. This "many-sidedness" may be seen in the Christian community's relationships to the state, society, education, the arts, social welfare, and family and personal life. (C.H.Li.)

CHURCH AND STATE

The relationship of Christians and Christian institutions to forms of the political order has shown an extraordinary diversity in the course of church history; there have been, for example, theocratically founded monarchies, democracies, and communist community orders. In various periods, however, political revolution, based on theological foundations, to eliminate older "Christian" state forms has also belonged to this diversity.

In certain eras of church history the aspiration for the Kingdom of God stimulated political and social strivings for its realization that included elements of power and dominion. The political power of the Christian proclamation of the coming sovereignty of God resided in its promise of both the establishment of a kingdom of peace and the execution of judgment.

The church as an ecclesiastical state

The church, like the state, has been exposed to the temptation of power. The attempt to establish a kingdom of peace resulted in the transformation of the church into an ecclesiastical state. This took place in the development of the Roman Papal States, but it also occurred to a lesser degree in several theocratic churches and was attempted in Calvin's ecclesiastical state in Geneva in the 16th century. In these cases the state declared itself a Christian state and the executor of the spiritual, political, and social commission of the church; it understood itself to be the representative of the Kingdom of God. This development took place in both the Byzantine and the Carolingian empires as well as in the medieval Holy Roman Empire.

The struggle between the church, understanding itself as state, and the state, understanding itself as representative of the church, not only dominated the Middle Ages but also continued into the Reformation period. The wars of religion in the era of the Reformation and Counter-Reformation discredited in the eyes of many the theological and metaphysical rationales for a Christian state. In the period of the Enlightenment, this led to the idea of the relationship of church and state as grounded upon ideas of natural law and, with Friedrich Schleiermacher among others, to the advocacy of legal separation of church and state.

The history of church and state. *The church and the Roman Empire.* In the early church the attitude of the Christian toward the political order was determined by the imminent expectation of the Kingdom of God, whose miraculous power was already beginning to be visibly realized in the figure of Jesus Christ. The importance of the existing political order was, thus, negligible, as expressed in the saying of Jesus, "My kingship is not of this world." Orientation toward the coming kingdom of peace placed Christians in tension with the state, which made demands upon them that were in direct conflict with their faith.

This contrast was developed most pointedly in the rejection of the emperor cult and of certain state offices—above all, that of judge—to which the power over life and death was professionally entrusted. Although opposition to fundamental orderings of the ruling state was not based upon any conscious revolutionary program, contemporaries blamed the expansion of the Christian Church in the Roman Empire for an internal weakening of the empire on the basis of this conscious avoidance of many aspects of public life, including military service.

Despite the early Christian longing for the coming Kingdom of God, even the Christians of the early generations acknowledged the pagan state as the bearer of order in the old eon, which for the time being continued to exist. Two contrary views thus faced one another within the Christian communities. On the one hand, under the influence of Pauline missions, was the idea that the "ruling body"—*i.e.,* the existing political order of the Roman Empire—was "from God . . . for your good" (Romans 13:1–4) and that Christians should be "subject to the govern-

ing authorities." Another similar idea held by Paul (in 2 Thessalonians) was that the Roman state, through its legal order, "restrains" the downfall of the world that the Antichrist is attempting to bring about. On the other hand, and existing at the same time, was the apocalyptic identification of the imperial city of Rome with the great whore of Babylon (Revelation 17:3–7). The first attitude, formulated by Paul, was decisive in the development of a Christian political consciousness. The second was noticeable especially in the history of radical Christianity and in radical Christian pacifism, which rejects cooperation as much in military service as in public judgeship.

The church and the Byzantine, or Eastern, Empire. In the Byzantine Empire the emperor Constantine granted himself, as "bishop of foreign affairs," certain rights to church leadership. These concerned not only the "outward" activity of the church but also encroached upon the inner life of the church—as was shown by the role of the emperor in summoning and leading imperial councils to formulate fundamental Christian doctrine and to ratify their decisions.

In the Byzantine era there evolved the concept of what has been called caesaropapism, a system in which the harmony between church and state shifted more and more in favour (in terms of power) of the emperor. His ecclesiastical authority was endowed with the idea of the divine right of kings, which was symbolically expressed in the ceremony of crowning and anointing the emperor. This tradition was later also continued in the Russian realms, where the tsardom claimed a growing authority for itself even in the area of the church.

The church and Western states. Conversely, the theocratic claim to dominion by the church freely developed in the sphere of the Roman Catholic Church after the state and administrative organization of the Roman Empire in the West collapsed in the chaos following the barbarian ethnic migrations. In the political vacuum that arose in the West because of the invasion by the German tribes, the Roman Church was the single institution that still preserved in its episcopal dioceses the Roman provincial arrangement. In its administration of justice the church largely depended upon the old imperial law and—in a period of legal and administrative chaos—was viewed as the only guarantor of order. The Roman popes used this power, which was in fact allotted to them by circumstances, to develop a specific ecclesiastical state and to base this state upon a new theocratic ideology—the idea that the pope was the representative of Christ and the successor of Peter. From this perspective the Roman popes detached themselves from the power of the Byzantine emperor, to whom they were indeed subordinate according to prevailing imperial law.

The break between Rome and Byzantium

The Roman bishops beginning with Gregory I the Great (reigned 590–604) turned to missionizing the peoples of the West. Under Gregory the church in Spain, Gaul, and northern Italy was strengthened, and England was converted to Roman Christianity. Succeeding popes convinced the rulers of the Frankish (Germanic) kingdom in the 8th century of their leadership role; they also succeeded in winning them as protectors of the papal dominion. These rulers were the first of the German kings to join themselves to the Roman Church. The relationship created a new area of tension. Whereas rulers considered the pope as a member of the Christian state and therefore under its protection and laws, the popes saw rulers as members of the church and therefore subject to the rule of God through St. Peter's successors. Moreover, the emperor Charlemagne claimed for himself the right to appoint the bishops of his empire, who were more and more involved in political affairs. These conflicting perspectives were the cause of interminable struggles between popes and rulers throughout the Middle Ages.

In the course of this development, the process of the feudalization of the church—unique in church history—occurred. Ruling political leaders in this system occupied significant positions in the church; by virtue of patronage this development encompassed the whole imperial church. At the conclusion of this development, bishops in the empire were simultaneously the reigning princes of their dioceses; they often were much more interested in the political tasks of their dominion than in the spiritual.

The feudalization of the church in the West

In the great church-renewal movement, which extended from its beginnings at the monastery at Cluny (France) in the 10th century and lasted until the reign of Pope Gregory VII in the 11th century, the papal church rejected both the sacred position of the king and the temporal position of bishops, who were awarded their rights and privileges by the king. This renewal movement proclaimed the freedom of the church from state authority as well as its preeminence over worldly powers. This struggle, now remembered as the Investiture Controversy, was fought out as a dramatic altercation between the papacy and the empire. The church did not, however, gain a complete victory in terms of papal claims of full authority over the worldly as well as the spiritual realms.

With the weakening of the Holy Roman Empire, the European nation-states arose as opponents of the church. The papal ideology had developed with respect to controlling emperors and was not suited to deal effectively with kings of nation-states. This was first clearly evident with the humiliation of Pope Boniface VIII by King Philip of France and the subsequent Babylonian Captivity of the church, when the papacy was forced to reside in Avignon (1309–77).

Contributing to the strengthening of the nation rulers' right of ecclesiastical supervision was the problem of papal schism, initiated upon the return of the papacy to Rome by the deposition of one pope and the election of another, with both claiming legitimacy. Popes and counterpopes reigning simultaneously mutually excommunicated one another, thus demeaning the esteem of the papacy. The schisms spread great uncertainty among the believers of the empire about the validity of the consecration of bishops and the sacraments as administered by the priests they ordained. The schism also fueled desires for a parliamentary form of church government and contributed to the rise of the 15th-century conciliar movement, which posited the supreme authority of ecumenical councils in the church.

The 16th-century Reformation forced the church to face its purely spiritual tasks and placed Reformation law as well as the legal powers of church leadership in the hands of the princes. Under King Henry VIII a revolutionary dissociation of the English Church from papal supremacy took place. In the German territories the reigning princes became, in effect, the legal guardians of the Protestant episcopate—a movement already in the process of consolidation in the late Middle Ages. The development in the Catholic nation-states, such as Spain, Portugal, and France, occurred in a similar way.

Church leadership under the control of the state

The democratic ideas of the freedom and equality of Christians and their representation in a communion of saints by virtue of voluntary membership had been disseminated in various medieval sects (*e.g.*, Cathari, Waldenses, Hussites, and the Bohemian Brethren) and were reinforced during the Reformation by groups such as the Hutterites, Mennonites, and Schwenckfelders and the followers of Thomas Müntzer. Under the old ideal of an uncompromising realization of the Sermon on the Mount, there arose anew in these groups a renunciation of certain regulations of the state, such as military service and the acceptance of state offices (judgeship), a radical pacifism, and the attempt to structure their own form of common life in Christian, communist communities. Many of their political ideas—at first bloodily suppressed by the Reformation and Counter-Reformation states and churches—were later prominent in the Dutch wars of independence and in the English Revolution, which led to a new relationship between church and state.

In the Thirty Years' War (1618–48), confessional antitheses were settled in devastating religious wars, and the credibility of the feuding ecclesiastical parties was thereby called into question. Subsequently, from the 17th century on, the tendency toward a new, natural-law conception of the relationship between state and church was begun and continued. Henceforth, in the Protestant countries, state sovereignty was increasingly emphasized vis-à-vis the churches. The state established the right to regulate ed-

ucational and marriage concerns as well as all foreign affairs of the church. A similar development also occurred in Roman Catholic areas. In the second half of the 18th century Febronianism demanded a replacement of papal centralism with a national church episcopal system; in the German *Reich* an enlightened state-church concept was established under Josephinism (a view advocated by Joseph II [reigned 1765–90]) through the dismantling of numerous ecclesiastical privileges. The Eastern Orthodox Church also was drawn into this development under Peter the Great.

The separation of church and state

The separation of church and state as proclaimed during the French Revolution in the latter part of the 18th century was the result of Reformational strivings toward a guarantee for the freedom of the church and the natural-law ideas of the Enlightenment; it was aggravated by the social revolutionary criticism against the wealthy ecclesiastical hierarchy. The separation of church and state was also achieved during and after the American Revolution as a result of ideas arising from the struggle of the Puritans against the English episcopal system and the English throne. After the state in France had undertaken the task of creating its own political, revolutionary substitute religion in the form of a "cult of reason," which was foreshadowed by Rousseau's discourse on "la religion civile," a type of separation of church and state was achieved. The French state took over education and other hitherto churchly functions of a civic nature.

From the late 18th century on, two fundamental attitudes developed in matters related to the separation of church and state. The first, as implied in the Constitution of the United States, was supported by a tendency to leave to the church, set free from state supervision, a maximum freedom in the realization of its spiritual, moral, and educational tasks. In the United States, for example, a comprehensive church school and educational system has been created by the churches on the basis of this freedom, and numerous universities have been founded by churches. The separation of church and state by the French Revolution and later in the Soviet Union and the countries under the Soviet Union's sphere of influence was based upon an opposite tendency. The attempt was to totally exterminate the church and to replace it with nationalism.

In contrast to this, National Socialism in Germany under Hitler showed paradoxical contradictions. On the one hand, Nazi propaganda pursued a consciously anti-Christian polemic against the church; it proceeded to arrest those clergy opposed to the Nazi worldview and policies.

Hitler's concordat with the Vatican

On the other hand, Hitler placed the greatest value upon concluding with the Vatican in 1934 a concordat that granted the Roman Catholic Church more special rights in the German *Reich* than had ever been granted it in any earlier concordat. The concordat with the Vatican represented the first recognition of the Hitler regime by a European government and was viewed by Hitler as a method of entrance into the circle of internationally recognized political powers.

In Germany the old state-church traditions had already been eliminated in the revolution of 1918, which, with the abolition of the monarchical system of government, also deprived the territorial churches of their supreme Protestant episcopal heads. In the German Weimar Constitution the revolution had earlier sanctioned the separation of church and state. State-church traditions were maintained in various forms in Germany, not only during the Weimar Republic but also during the Hitler regime and afterward in the Federal Republic of Germany. Thus, through state agreements, definite special rights, primarily in the areas of taxes and education, were granted to both the Roman Catholic Church and the Evangelical (Lutheran-Reformed) churches of the individual states.

Even in the United States, however, the old state-church system, overcome during the American Revolution, still produces aftereffects in the form of tax privileges of the church (exemption from most taxation), the exemption of the clergy from military service, and the financial furtherance of confessional school and educational systems through the state. These privileges have been questioned and even attacked by certain segments of the American public.

Church and state in Eastern and Western theology. The two main forms of the relationship between church and state that have been predominant and decisive through the centuries and in which the structural difference between the Roman Catholic Church and Eastern Orthodoxy becomes most evident can best be explained by comparing the views of two great theologians: Eusebius of Caesarea and Augustine.

The views of Eusebius of Caesarea. Eusebius of Caesarea (*c.* 260–*c.* 340) was the court theologian of Emperor Constantine the Great, who formed the Orthodox understanding of the mutual relationship of church and state. He saw the empire and the imperial church as sharing a close bond with one another; in the centre of the Christian empire stood the figure of the Christian emperor rather than that of the spiritual head of the church.

The mutual relationship of church and state

Eusebius made this idea the basis of his political theology, in which the Christian emperor appears as God's representative on Earth in whom God himself "lets shine forth the image of his absolute power." He is the "Godloved, three times blessed" servant of the highest ruler, who, "armed with divine armor cleans the world from the horde of the godless, the strong-voiced heralds of undeceiving fear of God," the rays of which "penetrate the world." Through the possession of these characteristics the Christian emperor is the archetype not only of justice but also of the love of humankind. When it is said about Constantine, "God himself has chosen him to be the lord and leader so that no man can praise himself to have raised him up," the rule of the Orthodox emperor has been based on the immediate grace of God.

The Orthodox interpretation of the Christian emperor

This religious interpretation of the Christian emperor reinterpreted in the Christian sense the ancient Roman institution of the god-emperor. Some of Eusebius' remarks echo the cult of the Unconquered Sun, the Sol Invictus, who was represented by the emperor according to pagan understanding. The emperor—in this respect he also resembled the pagan god-emperor who played the role of the *pontifex maximus* (high priest) in the state cult—took the central position within the church as well. He summoned the synods of bishops, "as though he had been appointed bishop by God," presided over the synods, and granted judicial power for the empire to their decisions. He was the protector of the church who stood up for the preservation of unity and truth of the Christian faith and who fought not only as a warrior but also as an intercessor, as a second Moses during the battle against God's enemies, "holy and purely praying to God, sending his prayers up to him." The Christian emperor entered not only the political but also the sacred succession of the Roman god-emperor. Next to such a figure, an independent leadership of the church could hardly develop.

Orthodox theologians have understood the coexistence of the Christian emperor and the head of the Christian church as *symphōnia,* or "harmony." The church recognized the powers of the emperor as protector of the church and preserver of the unity of faith and limited its own authority to the purely spiritual domain of preserving the Orthodox truth and order in the church. The emperor, on the other hand, was subject to the spiritual leadership of the church as far as he was a son of the church.

The relationship between patriarch and emperor

The special position of the imperial ruler and the function of the Byzantine patriarch as the spiritual head of the church have been defined in the *Epanagoge,* the judicial ruling establishing this relationship of church and state. The church-judicial affirmation of this relationship in the 6th and 7th centuries made the development of a judicial independence of the Byzantine patriarch in the style of the Roman papacy impossible from the beginning.

The *Epanagoge,* however, did not completely subject the patriarch to the supervision of the emperor but rather directed him expressly "to support the truth and to undertake the defense of the holy teachings without fear of the emperor." Therefore, the tension between the imperial reign that misused its absolutism against the spiritual freedom of the church and a church that claimed its spiritual freedom against an absolutist emperor or tsar was

characteristic for the Byzantine and Slavic political history but not the same as the political tension between the imperial power and the politicized papacy that occurred in the West.

The answers of the *City of God*

The views of Augustine. Augustine's *City of God* attempted to answer the most painful event of his century: the fall of Rome. Augustine responded to the existential shock and dismay his contemporaries experienced with the collapse of their world by a literary demolition of their nostalgic paganism. From Augustine's perspective the "splendid vices" of the pagans had led inexorably to the fall of an idolatrous world. In sharp contrast to this "earthly city," epitomized by Rome but everywhere energized by the same human desires for praise and glory, Augustine projected the "most glorious city" of praise and thanks to God, the heavenly Jerusalem, a historical image of which was the new Rome of the Catholic Church. However, Augustine did not simply identify the state with the earthly city and the church with the city of God. He perceived that the state existed not simply in opposition to God but as a divine instrument for the welfare of humankind. The *civitas dei* and the *civitas terrena* finally correspond neither to church and state nor to heaven and earth. They are rather two opposed societies with antagonistic orders of value that intersect both state and church and in each case show the radical incompatibility of the love of God with the values of worldly society.

Later developments. Based upon Augustine's views, the historical development of the church in the Latin West took a different course, one away from the Byzantine imperial church. In the West a new power was formed—the Roman Church, the church of the bishop of Rome. This church understood itself as the successor of the extinct Roman Empire. In the political vacuum of the West that was created by the invasion of the Germans and the destruction of the Roman state and administrative apparatus, the church became great and powerful as the heir to the Roman Empire. Only within this vacuum could the idea of the papacy develop in which the great popes, as bishops of Rome, stepped into the position of the vanished emperors.

The Donation of Constantine

It was in this context that the judicial pretense of the "Gift of the emperor Constantine"—the Donation of Constantine—became possible, to which the later development of the papacy was connected. The Donation attempted to reconstruct the history of the Roman papacy in retrospect in order to make legitimate the newly gained ecclesiastical and political position of the popes after the extinction of the Western Roman imperial reign. This fabrication entered papal ideology in written form through the mid-9th-century resource for canon law known as the Pseudo-Isadorian Decretals. The exposure of the Donation as a forgery did not occur until the 15th century. The Donation is the account of Constantine's purported conferring upon Pope Sylvester I (reigned 314–335) of the primacy of the West, including the imperial symbols of rulership. The Pope returned the crown to Constantine, who in gratitude moved the capital to Byzantium (Constantinople). The Donation thereby explained and legitimated a number of important political developments and papal claims, including the transfer of the capital to Byzantium, the displacement of old Rome by the new Rome of the church, papal secular authority, and the papal right to create an emperor by crowning him. The latter would be used to great effect when Pope Leo III crowned Charlemagne king of the Romans in 800. The force of this action was of great significance throughout the Middle Ages as popes exerted authority over the emperors of the Holy Roman Empire, and it explains the symbolic significance of Napoleon's taking the crown from Pope Pius VII's hands to crown himself.

This was the point of separation from which the developments in the East and in the West led in two different directions. The growing independence of the West was markedly illustrated by the Donation of Pepin (Pepin, father of Charlemagne, was anointed king of the Franks by Pope Stephen III in 754), which laid the foundation of the Papal States as independent of any temporal power and gave the pope the Byzantine exarchate of Ravenna. At this time the development of two different types of a Christian idea of the state and of the church began, and it subsequently ended in the schism between Rome and Byzantium in 1054.

The idea of the church as a state existed not only in the Roman theocracy and in the papal idea of the church, but it also appeared in a new democratic form and in strict contrast to its absolutist Roman model in some Reformation church and sect developments and in Free churches of the post-Reformation period. The sects of the Reformation period renewed the old idea of the Christian congregation as God's people, wandering on this Earth—a people connected with God, like Israel, through a special covenant. This idea of God's people and the special covenant of God with a certain chosen group caused the influx of theocratic ideas, which were expressed in forms of theocratic communities similar to states and led to formations similar to an ecclesiastical state. Such tendencies were exhibited among radical Reformation groups (*e.g.*, the Münster prophets), Puritans in Massachusetts, and various groups of the American Western frontier. One of the rare exceptions to early modern theocratic theology was Luther's sharp distinction of political and ecclesial responsibilities by his dialectic of law and gospel. He commented that it is not necessary that an emperor be a Christian to rule, only that he possess reason.

The Mormon attempt to establish a theocratic state

The latest attempt to form a church-state by a sect that understood itself as the chosen people distinguished by God through a special new revelation was undertaken by the Mormons, the "Latter-day Saints." Based on the prophetic direction of their leaders, they attempted to found the state Deseret, after their entrance into the desert around the Great Salt Lake in Utah. The borders of the state were expected to include the largest part of the area of the present states of Utah, California, Arizona, Nevada, and Colorado. The Mormons, however, eventually had to recognize the fact that the comparatively small centre state, Utah, of the originally intended larger Mormon territory, could not exist as a theocracy (though structured as other secular models) under a government of Mormon Church leaders. Reports (some apparently spurious) by federal agents hostile to the church and widespread revulsion toward the Mormon practice of polygyny mitigated against federal sanction of the church leadership as the governmental heads of the proposed state. Utah eventually became a federal state of the United States.

The enlightened absolutist state of the 18th century basically took over the secularized form of the old Christian government that consciously took into account the equality of Christian denominations.

CHURCH AND SOCIETY

Preserving or improving the status quo

Ever since the Reformation, the development of Christianity's influence on the character of society has been twofold. In the realm of state churches and territorial churches, its influence has been a strong element in preserving the status quo of society. Thus, in England, the Anglican Church remained an ally of the throne, as did the Protestant churches of the German states. In Russia the Orthodox Church continued to support the feudal society founded upon the monarchy, and even the monarch carried out a leading function within the church as protector.

Though the impulses for transformation of the social order according to the spirit of the Christian ethic came more strongly from the radical Free churches and sects, churches within the established system of state and territorial churches made positive contributions in improving the status quo. In 17th- and 18th-century Germany, Lutheran clergy, such as August Francke (1663–1727), were active in establishing poorhouses, orphanages, schools, and hospitals. In England, Anglican clergymen, such as Frederick Denison Maurice and Charles Kingsley in the 19th century, began a Christian social movement in the throes of the Industrial Revolution. Their movement brought a Christian influence to the conditions of life and work in industry. Johann Hinrich Wichern proclaimed, "There is a Christian Socialism," at the Kirchentag Church Convention in Wittenberg, Ger., in 1848, the year of the publication of the *Communist Manifesto*, and created the

"Inner Mission" in order to address "works of saving love" to all suffering spiritual and physical distress. The diaconal movements of the Inner Mission were concerned with social issues, prison reform, and care of the mentally ill. Only in tsarist Russia did the church fail in matters concerning social problems and the Industrial Revolution.

The Anglo-Saxon Free churches made great efforts to bring the social atmosphere and living conditions into line with a Christian understanding of human life. Methodists and Baptists addressed their message mainly to those segments of society that were neglected by the established church. They recognized that the distress of the newly formed working class, a consequence of industrialization, could not be removed by the traditional charitable means used by the state churches. The fact that in Germany, in particular, the spiritual leaders of the so-called revival movement, such as Friedrich Wilhelm Krummacher (1796–1868) and others, denied the right of self-organization to the workers by claiming that all earthly social injustices would receive compensation in heaven caused Karl Marx and Friedrich Engels to separate themselves completely from the church and its purely charitable attempts at a settlement of social conflicts and to declare religion with its promise of a better beyond as the "opiate of the people." This reproach, however, was as little in keeping with the social-ethical activities of the Inner Mission and of Methodists and Baptists as it was with the selfless courage of the Quakers, who fought against social demoralization, against the catastrophic situation in the prisons, and, most of all, against slavery.

The consequences of industrialization

The problem of slavery and persecution. The fight against slavery has passed through many controversial phases in the history of Christianity. Paul recommended to Philemon that he accept back his runaway slave Onesimus, "no longer as a slave but more than a slave, as a beloved brother . . . both in the flesh and in the Lord" (verse 16). Although the biblical writings made no direct attack upon the ancient world's institution of slavery, its proleptic abolition in community with Christ—"There is neither Jew nor Greek, there is neither slave nor free, there is neither male nor female; for you are all one in Christ Jesus" (Galatians 3:28)—has been a judgment upon the world's and the Christian community's failure to overcome slavery and all forms of oppression. Medieval society made only slow progress in the abolition of slavery. One of the special tasks of the orders of knighthood was the liberation of Christian slaves who had fallen captive to the Muslims; and special knightly orders were even founded for the ransom of Christian slaves.

With the discovery of the New World, the institution of slavery grew to proportions greater than had been previously conceived. The widespread conviction of the Spanish conquerors of the New World that its inhabitants were not really human in the full sense of the word and therefore could be made slaves in good conscience added to the problem. The attempt of missionaries, such as Bartolomé de Las Casas in 16th-century Peru, to counter the inhuman system of slavery in the colonial economic systems finally introduced the great basic debate concerning the question of human rights. A decisive part in the elaboration of the general principles of human rights was taken by the Spanish and Portuguese theologians of the 16th and 17th centuries, especially Francisco de Vitoria. Even modern natural law, however, could still be interpreted in a conservative sense that did not make slavery contrary to its provisions. Puritanism, however, fought against slavery as an institution. In German Pietism, Nikolaus Ludwig, Graf von Zinzendorf, who became acquainted with slavery on the island of Saint Croix in the Virgin Islands, used his influence on the King of Denmark for the human rights of the slaves. The Methodist and Baptist churches advocated abolition of slavery in the United States in the decisive years preceding the foundation of the New England Anti-Slavery Society in Boston in 1832 by William Lloyd Garrison. In regard to the fight against slavery in England and in The Netherlands, which was directed mainly against the participation of Christian trade and shipping companies in the profitable slave trade, the Free churches were very active. The overcoming of the institution of slavery did not end racial discrimination. Martin Luther King, Jr., Baptist pastor and Nobel laureate, led the struggle for civil rights in the United States until his assassination in 1968. In South Africa in the 1980s, Desmond Tutu, Anglican archbishop and Nobel laureate, exemplified a continuing Christian struggle for human rights.

The beginning of the abolition of slavery

The fight against slavery is only a model case in the active fight of the Christian churches and fellowships against numerous other attempts at desecration of a Christian understanding of the nature of humanity, which sees in every human being a neighbour created in God's image and redeemed by Christ. Similar struggles arose against the persecution of the Jews and the elimination of members of society characterized by political or racist ideology as "inferior." In Germany the members of the Confessing Church fought against the practices of National Socialism, which called for the elimination of the mentally ill and the inmates of mental and nursing institutions, who were considered "unfit to live."

Theological and humanitarian motivations. Decisive impulses for achieving changes in the social realm in the sense of a Christian ethic have been and are initiated by men and women in the grasp of a deep personal Christian experience of faith, for whom the message of the coming Kingdom of God forms the foundation for faithful affirmation of social responsibility in the present world. Revival movements have viewed the Christian message of the Kingdom of God mainly as an impulse for reorganization of the secular conditions of society in the sense of a Kingdom of God ethic. Under the leadership of an American Baptist theologian, Walter Rauschenbusch (1861–1918), the so-called Social Gospel movement spread in the Anglo-Saxon countries. A corresponding movement was started with the Christian social conferences by German Protestant theologians, such as Paul Martin Rade (1857–1940) of Marburg. The basic idea of the Social Gospel—*i.e.,* the emphasis on the social-ethical tasks of the church—gained widespread influence within the ecumenical movement and especially affected Christian world missions. In many respects modern economic and other forms of aid to developing countries—including significant ecumenical contributions from the World Council of Churches, the World Alliance of Reformed Churches, the Lutheran World Federation, and the Roman Catholic Church—have now succeeded the Social Gospel.

Decisive impulses for achieving social change

There is concern on the part of some Christians that these developments reduce the Christian message to a purely secular social program that is absorbed by political programs. Others in the Christian community believe that faithful responsibility in and to the world requires political, economic, and social assistance to oppressed peoples with the goal of their liberation to a full human life.

Changes and problems in the Christian social message

CHURCH AND EDUCATION

Intellectualism versus anti-intellectualism. In contrast to Tertullian's anti-intellectual attitude, an exactly opposite attitude toward intellectual activities has also made itself heard from the beginning of the Christian Church (*e.g.,* by Clement of Alexandria). It also has its basis in the nature of Christian faith. In the 11th century Anselm of Canterbury expressed it in the formula *fides quaerens intellectum* ("faith seeking understanding"), a formula that has become the rallying point for scholastics of all times. Because people have been endowed with reason, they have an urge to express their experience of faith intellectually, to translate the contents of faith into concepts, and to formulate beliefs in a systematic understanding of the correlation between God, humankind, and creation. Christians of the 1st century came from the upper levels of society and were acquainted with the philosophy and natural science of their time. Justin Martyr, a professional philosopher, saw Christian revelation as the fulfillment, not the elimination, of philosophical understanding. The Logos term of the opening chapter of the Gospel According to John is the point of departure for the intellectual history of salvation. The light of the Logos (a Greek word meaning "word" or "reason," with the sense of divine or universal reason permeating the intelligible world) had made itself manifest in a number of sparks and seeds in

human history even before its incarnation in the person of Jesus Christ.

These two contrasting opinions have stood in permanent tension with one another. In medieval Scholasticism the elevation of Christian belief to the status of scientific universal knowledge was dominant. Theology became the instructor of the different sciences, organized according to the traditional classification of trivium (grammar, rhetoric, and dialectic) and quadrivium (music, arithmetic, geometry, and astronomy) and incorporated into the system of education as "servants of theology." This system of education became part of the structure of the universities that were founded in the 13th century. The different sciences only gradually gained a certain independence.

Theology as the instructor of the various sciences

With the Reformation there was widespread concern for education because the Reformers desired everyone to be able to read the Bible. Their concern was the beginning of universal, public education. Luther also argued that it was necessary for society that its youth be educated. He held that it was the duty of civil authorities to compel their subjects to keep their children in school so "that there will always be preachers, jurists, pastors, writers, physicians, schoolmasters, and the like, for we cannot do without them."

Open conflict between science and theology occurred only when the traditional biblical view of the world was seriously questioned, as in the case of the Italian astronomer Galileo (1633). The principles of Galileo's scientific research, however, were themselves the result of a Christian idea of science and truth. The biblical faith in God as Creator and incarnate Redeemer is an explicit affirmation of the goodness, reality, and contingency of the created world—assumptions underlying scientific work. Thus, in the 20th century, William Temple, archbishop of Canterbury, could assert that Christianity is an avowedly materialistic religion. Positive tendencies concerning education and science have always been dominant in the history of Christianity, even though the opposite attitude arose occasionally during certain periods. Thus the German astronomer Johannes Kepler (1571–1630) spoke of celebrating God in science.

The attitude that had been hostile toward intellectual endeavours was less frequently heard after the Christian Church had become the church of the Roman Empire. But the relationship between science and theology was also attacked when the understanding of truth that had been developed within theology was turned critically against the dogma of the church itself. This occurred, for instance, after the natural sciences and theology had turned away from total dependence upon tradition and directed their attention toward experience—observation and experiment. A number of fundamental dogmatic principles and understandings were thus questioned and eventually abandoned. The struggle concerning the theory of evolution (*e.g.*, the Scopes Trial in Tennessee in 1925) has been a conspicuous modern symptom of this trend.

The estrangement between theology and science

The estrangement of theology and natural science in the modern period was a complex development related to confessional controversies and wars in the 16th and 17th centuries and philosophical perspectives in the 18th and 19th centuries. The epistemological foundation of faith was radically called into question by the Scottish philosopher David Hume. Building upon Hume's work, the German philosopher Immanuel Kant advocated freedom from any heteronomous authority, such as the church and dogmas, that could not be established by reason alone. Scholars withdrew from the decisions of church authorities and were willing to subject themselves only to critical reason and experience. The rationalism of the Enlightenment appeared to be the answer of science to the claim of true faith that had been made by the churches, which had become untrustworthy through the religious wars and the influence of philosophy.

Forms of Christian education. The Christian Church created the bases of the Western system of education. From its beginning the Christian community faced external and internal challenges to its faith, which it met by developing and utilizing intellectual and educational resources. The response to the external challenge of rival religions and philosophical perspectives is termed apologetics—*i.e.*, the intellectual defense of the faith. Apologetic theologians from Justin Martyr in the 2nd century to Paul Tillich in the 20th have promoted critical dialogue between the Christian community, the educated world, and other religions. The internal challenges to the Christian community were met not only by formulating the faith in creeds and dogmas but also by passing this faith on to the next generations through education.

In the early Middle Ages a system of schools was formed at the seats of bishops to educate clergy and to teach the civil servants of the government and administrative offices. The school at the court of Charlemagne (which was conducted by clergy), the medieval schools of the religious orders, cathedrals, monasteries, convents, and churches, the flourishing schools of the Brethren of the Common Life, and the Roman Catholic school systems that came into existence during the Counter-Reformation under the leadership of the Jesuits and other new teaching orders contributed much to the civilization of the West. Equally important were the schools and educational reforms started by the German Reformers Luther, Philipp Melanchthon, Johann Bugenhagen, John and August Hermann Francke, and the Moravian reformers John Amos Comenius and the Graf von Zinzendorf. The church was responsible for the system of schools even after the Reformation. Only in the 18th century did the school system start to separate itself from its Christian roots and fall more and more under state control.

Effect of the separation of church and state

With the separation of church and state, both institutions have entered into tensely manifold relationships. In some countries the state has taken over the school system completely and does not allow private church schools except in a few special cases in which constant control is maintained regarding religious instruction as a part of the state's educational task. Other countries (*e.g.*, France) maintain school systems basically free of religion and leave the religious instruction to the private undertakings of the different churches. In the American Revolution the concept of the separation of state and church was a lofty goal that was supposed to free the church from all patronization by the state and to make possible a maximum of free activity, particularly in the area of education. On the other hand, the Soviet Union used its schools particularly for an anti-religious education based upon the state philosophy of dialectical materialism, practicing the constitutionally guaranteed freedom of anti-religious propaganda in schools, though the churches were forbidden to give any education outside their worship services.

A second issue that results from the separation of church and state is the question of state subsidies to private church schools. These are claimed in those countries in which the church schools in many places take over part of the functions of the state schools (*e.g.*, in the United States). After the ideological Positivism and the Materialism of the 19th century faded away in many areas, it was realized that religious life had had an important role in the cultural development of the West and the New World and that the practiced exclusion of religious instruction from the curricula of the schools indicated a lack of balance in education. Based on new insights, it has therefore been maintained in the 20th century that religion should be adopted as a subject among the humanities. State universities in the United States, Canada, and Australia, which did not have theological faculties because of the separation of church and state, founded departments of religion of an interdenominational nature and included non-Christians as academic teachers of religion.

The Christian system of education led to the early founding of universities. The university was a creation of medieval Europe and spread from there to other continents after the 16th century. The universities that had been formed in the beginning through the unification of schools for monks and schools for regular clergy succeeded in gaining their relative independence by agreements with church and state. The universities represented the unity of education that was apparent in the common use of the Latin language, the teaching methods of lecture and disputation, the extended communal living in colleges, the

periodically changing leadership of an elected dean, the inner structure according to faculties or "nations," and the European recognition of the academic degrees.

The advent of humanism and the Reformation created a new situation for all systems of education, especially the universities. Humanists demanded plans to provide designated places for free research in academies that were princely or private institutions and, as such, not controlled by the church. On the other hand, the Protestant states of the Reformation created their own new state universities, such as Marburg in 1527, Königsberg in 1544, and Jena in 1558. As a counteraction, the Jesuits took over the leadership in the older universities that had remained Roman Catholic or else founded new ones in Europe and overseas.

In overseas areas, Christian education has had a twofold task. First, its function was to lay an educational foundation for evangelization of non-Christian peoples by forming a system of education for all levels from grammar school to university. Second, its function was to take care of the education of European settlers. To a large extent the European colonial powers had left the formation of an educational system in their colonies or dominions to the churches. In the Spanish colonial regions in America, Roman Catholic universities were founded very early (*e.g.,* Santo Domingo in 1538, Mexico and Lima in 1551, Guatemala in 1562, and Bogotá in 1573). In China, Jesuit missionaries acted mainly as agents of European education and culture (*e.g.,* astronomy, mathematics, and technology) in their positions as civil servants of the court.

Since the 18th century, the activities of competing Christian denominations in mission areas has led to an intensification of the Christian system of education in Asia and Africa. Even where the African and Asian states have their own system of schools and universities, Christian educational institutions have performed a significant function (St. Xavier University in Bombay and Sophia University in Tokyo are Jesuit foundations; Dōshisha University in Kyōto is a Japanese Presbyterian foundation).

Denominational colleges in the United States

In North America, Christian education took a different course. From the beginning, the churches took over the creation of general educational institutions. The various denominations did pioneer work in the field of education; a state school system was established only after the situation had consolidated itself. In the English colonies, later the United States, the denominations founded theological colleges for the purpose of educating their ministers and established universities dealing with all major disciplines, including theology, often emphasizing a denominational slant. Harvard University was founded in 1636 and Yale University in 1701 as Congregational establishments, and the College of William and Mary was established in 1693 as an Anglican institution. They were followed during the 19th century by other Protestant universities (*e.g.,* Southern Methodist University, Dallas, Texas) and colleges (*e.g.,* Augustana College, Rock Island, Ill.). In addition, many private universities were based upon a Christian idea of education according to the wishes of their founders.

Christian education has been undertaken in a variety of forms. The system of Sunday schools is nearly universal in all denominations. Confirmation instruction is more specialized, serving different tasks, such as preparation of the children for confirmation, their conscious acknowledgment of the Christian ethic, of the Christian confessions, of the meaning of the sacraments, and of the special forms of congregational life. (E.W.B./C.H.Li.)

CHURCH AND THE ARTS

The Christian community has fostered the development of a Christian culture in all areas of life. In this development the arts have played major roles in expressing, communicating, and deepening the faith of the community. At times some art has been rejected because either the content or the form was perceived as incompatible with the faith of the community. For example, the antipathy of the early church, especially in Orthodox realms, to theatre was related to the perception that the Greek theatre was preoccupied with ancient myths and deities and that comedy excused immorality. Instrumental music also was rejected in Orthodoxy because of both its accustomed role in pagan cults and the belief that God should not be praised with "dead" materials. The Orthodox community did not completely reject dramatic and musical art, however, but transformed them into the service of the church through rich liturgical dramas and extraordinary choir music.

The didactic use of art

The didactic use of art, succinctly expressed by Pope Gregory I the Great in the phrase "images are the books of the laity," was present in the architecture and art of the churches constructed up to the modern period. The symbolic significance of the church building in the shape of a cross, its deep entrances leading into sacred space, the carefully engineered proportions of the building, the use of light and shadow in relation to statues and stained glass, the smells of candles and incense, not to mention the liturgy itself—all these forms, colours, sights, sounds, and smells worked to communicate a sense of the sacred. The sculptures and stained-glass windows were graphic presentations of biblical stories and moral instructions to which the preacher could point and to which the largely illiterate congregation could return for reflection and edification. The very location of the church in the centre of medieval towns and villages gave physical expression to the community's faith in God's presence in the world.

Until the Renaissance the arts were patronized by and in service to the Christian community. Since then there has been a growing independence of artists from the church. In the modern period the older "Christ against culture" concerns of the early church have once again been raised. The Christian community has by and large not found the criterion of religious subject matter satisfactory for its decisions about art. While the music of Richard Wagner may be regarded as inappropriate for the church because of his preoccupation with Teutonic gods and goddesses, a painting such as Picasso's "Guernica" depicting human sin and evil may be appropriate. At the same time a musical, literary, plastic, or graphic representation of Jesus may either vitiate and trivialize the faith of the community, as in modern sentimentalized "portraits" of Jesus, or profoundly express that faith, as in Matthias Grünewald's "Isenheim Altarpiece" portraying the Crucifixion.

The Christian community, sensitized by its Jewish roots and the Hebrew prohibition of idolatry, has been aware that the beauty of the holy may be twisted into the holiness of beauty. Thus, at various times in history there have been iconoclastic reactions to art. But for the most part the Christian community has appreciated and contributed to the didactic, expressive, and symbolic representation of faith and the human condition. (C.H.Li.)

CHURCH AND SOCIAL WELFARE

Curing and caring for the sick. *Healing the sick.* The Christian Church has administered its concern for the sick in a twofold manner: both by healing the sick and by expressing concern and caring for them. The practice of healing has retreated into the background in modern times, but healing played a decisive role in the success of the early church and was important in missionary apologetics. In the Gospels, Jesus appears as a healer of body and soul. The title "Christ the Physician" was the most popular name for the Lord in missionary preaching of the first centuries. Even the Apostles are characterized as healers. The apologetics of the church of the 2nd to 4th century used numerous miraculous healings as arguments for the visible presence of the Holy Spirit in the church. The Fathers of the first centuries interpreted the entire sphere of charismatic life from the basic concepts that Christ is the physician, the church the hospital, the sacraments the medication, and orthodox theology the medicine chest against heresy. Ignatius of Antioch called the Eucharist the "medication that produces immortality."

The history of charismatic healing has hardly been explored. Miracles of healing remain a characteristic attribute of the great Christian charismatics of the Roman Catholic Church as well as of the Eastern Orthodox. Healing within the church began to retreat only in connection with the transformation of the church into a state church under Constantine and with the replacement of free charismatics by ecclesiastical officials.

The early basis for healing was generally a demonological

The development of exorcism

interpretation of sickness: healing was often carried out as an exorcism—that is, a ceremonial liturgical adjuration of the demon that was supposed to cause the illness and its expulsion from the sick person. The development of exorcism is characteristic in that the office of the exorcist eventually became one of the lower levels of ordination, which led to the priesthood. Traditionally, exorcisms were connected not with the rite of baptism alone; the *Rituale Romanum* (*Roman Ritual*) contains many liturgical formulas for cases of demoniacal possession. Only the Enlightenment in the 18th century repressed the practice of exorcisms within the Roman Catholic Church.

In the churches of the Reformation, exorcism never completely vanished; in Pietistic circles several exorcists have appeared; *e.g.*, Johann Christoph Blumhardt the Elder (1805–80). With the motto "Jesus is Conquerer," Blumhardt transformed his healing centre at Bad Boll, Ger., into an influential resource for international missionary work. His son, Christoph Friedrich Blumhardt (1842–1919), continued his father's work and in sympathy with working-class needs included political action as a member of the Württemberg Diet. Since the latter part of the 19th century, different groups of the Pentecostal and charismatic movements have re-accepted the use of exorcistic rituals with great emphasis and—pointing to the power of the Holy Spirit—they claim the charisma of healing as one of the spiritual gifts granted the believing Christian. After the basic connection between healing of the body and healing of the soul and the psychogenic origin of many illnesses was acknowledged theologically and medically, different older churches, such as the Protestant Episcopal Church and even the Roman Catholic Church in the United States, have reinstituted healing services.

In terms of spiritual healing, one church has stood out in this respect in North America. Mary Baker Eddy (1821–1910), the founder of Christian Science, referred particularly to healing through the Spirit as her special mission. Based on her experience of a successful healing from a serious illness by Phineas Quimby, a pupil of the German hypnotist Franz Mesmer, she wrote her work *Science and Health with Key to the Scriptures* and founded the Church of Christ, Scientist. According to the instructions of its founder, Christian Science today carries out a practice of "spiritual healing" throughout the world.

Care for the sick. From the beginning another concern besides healing was care for the sick, an element of the earliest commandments of Christian ethics. At the Last Judgment, Christ the Judge will say to the chosen ones on his right hand: "I was sick and you visited me," and to the condemned on his left hand: "I was sick and you did not visit me." To the condemneds' surprised questions as to when they saw Christ sick and did not visit him, they will receive the answer: "As you did it not to one of the least of these, you did it not to me."

The concern for the Last Judgment

The first office created by the church in Jerusalem was the diaconate; it spread rapidly throughout the entire church. The care of the sick was carried out by the deacons and widows under the leadership of the bishop. This service was not limited to members of the Christian congregation but was directed toward the larger community, particularly in times of pestilence and plague. Eusebius included in his *Ecclesiastical History* the report that while the heathen fled the plague at Alexandria, "most of our brother-Christians showed unbounded love and loyalty" in caring for and frequently dying with the victims.

During the Middle Ages the monasteries took over the care of the sick and created a new institution, the hospital. The growing number of pilgrims to the Holy Land and the necessity of care of their numerous sick, who had fallen victim to the unfamiliar conditions of climate and life, led to knightly hospital orders, the most important of which was the Order of the Hospital of St. John of Jerusalem (later called the Knights of Malta). The service for the sick, which was carried out by the knights besides their military service for the protection of the pilgrims, was not elaborate.

In connection with the orders of mendicant friars, especially the Franciscans, civil hospital orders were formed. Even the hospital in Marburg that was founded by St. Elizabeth of Hungary (1207–31) on the territory of the Knights of the Teutonic Order was influenced by the spirit of St. Francis. Other hospitals were founded as autonomous institutions under the leadership or supervision of a bishop. The meaningful centralization of the different existing institutions became necessary with the growth of cities and was most frequently undertaken by city councils. The laity began to take over, but the spiritual and pastoral care of the patients remained a major concern.

The development of nursing orders and deaconess orders

In the realm of the Lutheran Reformation, the medieval nursing institutions were adapted to new conditions. The church constitutions in the different territories of Reformed churches stressed the duty of caring for the sick and gave suggestions for its adequate realization. The office of the deacon was supplemented by that of the deaconess; and these offices of service were considered part of the polity of the church of the New Testament. The Counter-Reformation brought a new impulse for caring for the sick in the Roman Catholic Church, insofar as special orders for nursing service were founded—*e.g.*, the Daughters of Charity, a non-enclosed congregation of women devoted to the care of the sick and the poor, by Vincent de Paul, who was a notable charismatic healer. A great number of new orders came into existence and spread the spirit and institutions of ecclesiastical nursing care throughout the world as part of Roman Catholic world missions.

In the realm of Protestantism, the Free churches led in the care of the sick. Methodists, Baptists, and Quakers all had a great share in this development, founding numerous hospitals throughout the world and supplying them with willing male and female helpers. German Lutheranism was influenced by these developments. In 1823 Amalie Sieveking developed a sisterhood analogous to the Daughters of Charity and was active in caring for the cholera victims of the great Hamburg epidemic of 1831. She was an inspiration to Theodor Fliedner, who founded the first Protestant hospital in Kaiserswerth in 1836 and created at the same time the female diaconate, an order of nurses that soon found worldwide membership and recognition. Florence Nightingale received training at Kaiserswerth, which was an important model for modern nursing schools.

Church hospitals and ecclesiastical nursing care still maintain a leading and exemplary role in the 20th century, although along with the general political and social development of the 19th century the city or communal hospital was founded and overtook the church hospital.

The founding of the Red Cross

The most impressive example of the universal spread of care for the sick was the founding of the Red Cross by the Swiss humanitarian Henri Dunant. The religious influence of Dunant's pious parental home in Geneva and the shocking impression he received on the battlefield of Solferino in June 1859 led him to work out suggestions that—after difficult negotiations with representatives of numerous states—led to the conclusion of the "Geneva convention regarding the care and treatment in wartime of the wounded military personnel." In the 20th century the activity of the Red Cross has embraced not only the victims of military actions but also peace activity, which includes aid for the sick, for the handicapped, for the elderly and children, and for the victims of all types of disasters everywhere in the world.

Care for widows and orphans. From the beginning the Christian congregation cared for the poor, the sick, widows, and orphans. The Letter of James says: "Religion that is pure and undefiled before God is this: to visit orphans and widows in their affliction." Widows formed a special group in the congregations and were asked to help with nursing care and other diaconic (from *diakonia,* or faith active in love and service to all) congregational tasks as long as they did not need help and care themselves.

The founding of orphanages and other institutions of mercy

The church had founded orphanages during the 4th century, and the monasteries took over this task during the Middle Ages. They also fought against the practice of abandoning unwanted children and established foundling hospitals. In this area, as in others, a secularization of church institutions took place in connection with the spreading autonomy of the cities. In the Reformed churches the establishment of orphanages was furthered systematically. In Holland almost every congregation had

its own orphanage, which was sustained through the gifts of the members.

Following the great wars of the 17th century, the orphanages were reorganized pedagogically, notably by August Hermann Francke, who connected the orphanage in Glaucha, Ger., which he had founded, with a modern system of secondary schools. Francke's orphanage became a model that was frequently imitated in England and also in North America. An exemplary proponent of comprehensive Christian caring and curing for the whole person and community was the Alsatian Lutheran pastor Johann Friedrich Oberlin (1740–1826). Responsible for a remote and barren area in the Vosges Mountains, Oberlin transformed the impoverished villages into prosperous communities. He led in establishing schools, roads, bridges, banks, stores, agricultural societies (with the introduction of potato cultivation), and industries. His nursery schools were imitated in many areas through "Oberlin Societies." These efforts provided a significant contribution to the development of modern welfare, which in the 20th century is mainly the responsibility of state, communal, or humanitarian organizations but is still characterized strongly by its Christian roots. (E.W.B./C.H.Li.)

Property, poverty, and the poor. The Christian community's relation to the questions of property, poverty, and the poor may be sketched in terms of four major perspectives, which have historically overlapped and sometimes coexisted in mutuality or contradiction. The first perspective, both chronologically and in continuing popularity, is personal charity. This was the predominant form of the church's relationship to the poor from the 1st to the 16th century. The second perspective supplements the remedial work of charity by efforts for preventive welfare through structural changes in society. This concern to remove causes of poverty was clearly expressed in the Reformation but was soon submerged in the profound sociopolitical and economic changes of the time. The third perspective is a retreat into the charity models of the earlier Christian community. Because of the overwhelming effects of the process of secularization and the human misery caused by industrialization, the key to social welfare was expressed in the Pietist maxim that social change depended upon the conversion of individuals. The fourth perspective, present in churches of the modern period, envisions systemic social change to facilitate redistribution of the world's wealth. Personal charity is not neglected, but the major goal is to change the unjust structures of world society.

The relationship of rich and poor

The early Christian community's teachings on property and poverty were marked by the tension between its expectation of support from the wealthy and its biblically rooted criticism of wealth. The solution was to place rich and poor in a symbiotic relationship oriented toward salvation. The rich supply the needs of the poor, who in turn provide the rich with the opportunity for good works and prayers for their salvation.

Augustine's doctrine of charity became the heart of Christian thought and practice. Augustine portrayed the Christian pilgrimage toward the heavenly city by analogy to a traveler's journey home. The city of God, humankind's true home, is characterized by the love of God even to the contempt of self, whereas the earthly city is characterized by the love of self even to the contempt of God. It is the goal—not the journey—that is ultimately important. The world and its goods must be used for the journey, but if they are enjoyed they direct the traveler away from God to the earth. This imagery incorporates into the heart of Christian theology the great medieval themes of pilgrimage, renunciation, alienation, and asceticism; and the biblical and early Christian suspicion of riches receives systematic theological articulation. Pride and covetousness are the major vices; humility and almsgiving are the major virtues; and poverty is endorsed as the favoured status for the Christian life.

This view did not, however, lead to a rejection of property and its importance for society. Against both Marcionite denigration of the world and Gnostic communism, respect for private property was maintained as integral to a comprehensive ethic. It was clear that without property Christians could not care for the needy. And, although Gregory of Nazianzus (*c.* 330–*c.* 389) linked private property to the Fall, he understood that the abolition of private property would not cure sin. Property and wealth should be shared, not relinquished. Yet the paradox of 2 Corinthians 6:10 remained: How could a Christian be poor yet make many rich, have nothing yet possess everything? The answers given were communal property, charity to the needy, avoidance of avarice, and concentration upon heavenly treasure. In this way the early Christian community achieved an aristocratic attitude to riches. The solutions of institutionalizing poverty in priesthood and monasticism, while rationalizing poverty as poverty of the spirit and material wealth as God's provision for ministry, formed the basis for medieval care of the poor.

The medieval Christian community promoted almsgiving within a theological framework oriented to the future salvation of the individual. Although this framework was a stimulus to insightful and humane laws and actions, it did not result in the formulation of policies to deal with the major social and economic changes that accompanied the late medieval shift from rural-agricultural society to urban-commercial society.

The most influential medieval thinker on the problem of property was Thomas Aquinas. Thomas saw community of goods as rooted in natural law because it makes no distinction of possessions. The natural law of common use protects every person's access to earthly goods and requires responsibility by everyone to provide for the needs of others. Private property, on the other hand, is rooted in positive law through human reason. In history, reason leads to the conclusion that the common good is served if everyone has disposition of his own property because there is more incentive to work, goods are more carefully used, and peace is better preserved when all are satisfied with what they have. Private property exists to serve the common good; thus, superfluous property is to be distributed as alms to the needy.

The other major effort to deal with property and poverty at this time was through rational direction and administration. As cities developed into political corporations, a new element entered welfare work: an organizing citizenry. Through their town councils, citizens began to claim the authority to administer the ecclesiastical welfare work of hospitals and poor relief. The process was accelerated by the Reformers, whose theology undercut the medieval idealization of poverty. According to the Reformers, righteousness before God was by faith alone apart from human works, and salvation was perceived as the foundation of life rather than its goal. Thus, the Reformation community found it difficult to rationalize the plight of the poor as a peculiar form of blessedness, and no salvific value either in being poor or in giving alms could be identified. When the Reformers turned to poor relief and social welfare, their new theological perspectives led them to raise questions of social justice and social structures. This was institutionalized in the "common chest" sections of Protestant church legislation, which spread throughout Europe from its origin in Wittenberg. The common chest—funded by church endowments, offerings, and taxes—was the community's financial resource for providing support to the poor, orphans, aged, unemployed, and underemployed through subsidies, low-interest loans, and gifts. The attempt to resolve social problems in the cities was a constitutive part of the early Reformation.

Reformation views of poverty

In the following centuries the heirs of Luther and Calvin, although producing noteworthy examples of compassion and charity for the poor, nevertheless lost their "fathers' " vision of a social ethic that was preventive as well as therapeutic. Like their Roman Catholic counterparts, the Protestants made noteworthy efforts to serve the poor but ignored the root causes of poverty.

In the 18th and 19th centuries the social institutions of Pietism, the Inner Mission, and European revival movements inspired social concern for the masses of people pauperized and proletarianized by industrialism. The Methodists in England undertook adult education, schooling, reform of prisons, abolition of slavery, and aid to alcoholics. Famous missions arose in Basel, London, and Paris. The Young Men's Christian Association (YMCA;

1844), Young Women's Christian Association (YWCA; 1855), and the Salvation Army (1865) were only some of the numerous charitable institutions and organizations created to alleviate modern ills. In 1848 Johann Wichern, founder of the Inner Mission, proclaimed that "love no less than faith is the church's indispensable mark."

Yet this Christian social concern hardly was aware of and rarely attempted to expose the origins of the social ills it strove to remedy. Wichern himself was aware that poverty is social, not natural, but his orientation, like that of others, was toward renewing society through evangelization. This attitude—that society is changed by changing the hearts of individuals—is still prevalent.

In recent years, however, the Christian community, especially in its ecumenical organizations, has begun to analyze the social problems of property and poverty from the standpoint of justice and the perspectives of the poor and oppressed. In 1970 the World Council of Churches (WCC) established the Commission for the Churches' Participation in Development (CCPD). Initially involved in development programs and the provision of technical services, the CCPD focus has shifted to the psychological and political character of the symbiosis of development and underdevelopment. This focus was endorsed at the 1975 WCC Assembly at Nairobi, Kenya, as "a liberating process aimed at justice, self-reliance and economic growth." Other church bodies, such as the Lutheran World Federation and the World Alliance of Reformed Churches, share this perspective. Emergency relief and development projects—the modern equivalents of charity—have not ceased, but there is growing realization, due to the increasing participation of so-called Third World churches, that the biblical themes of justice and liberation entail the creation of social structures to enhance human life, economic structures for just distribution of goods, and political structures to promote participation and minimize dependence. The present WCC paradigm for this mission is the church in solidarity with the poor.

Pastoral care. Pastoral care has always been of special importance in the Christian community. The biographies of the great charismatic ministers, beginning with the Fathers of the Eastern Church and the Western Church, testify to surprising variations of this pastoral care. The principal interest of pastoral care—whether exercised by clergy or laity—is the personal welfare of persons who are hurt, troubled, alienated, or confused within the context of ultimate concerns and meanings. The historical expressions of pastoral care have focused on the predominant—but not exclusive—expressions of ultimate concern characteristic of the period in question. According to Paul Tillich, in *The Courage to Be* (1952), these concerns may be described in terms of the anxieties of death (early church), guilt (Middle Ages), and meaninglessness (modern period). Thus, Ignatius addressed the terror of death when he termed the sacrament "the medicine of immortality"; Luther responded to the conscience tortured by guilt and uncertainty by proclaiming the free forgiveness of sin by grace alone, apart from human accomplishment; and the modern Christian community has utilized the insights of psychology and psychiatry in developing pastoral counseling and therapy responsive to modern anxieties. Fundamentally, however, pastoral care has always attempted to respond to the totality of human needs in every age in consonance with the words of Jesus Christ: "I was hungry and you gave me food, I was thirsty and you gave me drink, I was a stranger and you welcomed me, I was naked and you clothed me, I was sick and you visited me, I was in prison and you came to me" (Matthew 25:35–36).

The purpose of pastoral care

The first influential contribution to pastoral care after the New Testament was by Pope Gregory I the Great. His *Pastoral Care,* written after he became bishop of Rome in 590, was so influential that it became customary to present it to new bishops upon their ordination. This textbook of the medieval episcopate emphasized the role of the pastor as shepherd of souls.

The medieval institutionalization of pastoral care in the sacrament of penance led to certain deficits in practice: the exclusion of the laity by emphasis upon the central role of the priest and the distortion of its original spiritual purposes of prayer, repentance, and forgiveness of sins by the introduction of paid indulgences. The indulgence abuse sparked the Reformation critique of the sacrament of penance. This in turn led to the Reformers' emphasis upon lay as well as clerical responsibility for pastoral care as expressed in their teaching of "the priesthood of all believers." The Reformation insistence upon justification by grace alone shifted the burden of proof for salvation from human accomplishment to divine promise. By "letting God be God," the Reformers claimed that persons were free to be human. This shift of theological focus, from an otherworldly achievement to a this-worldly trust in God, facilitated a renewed holistic awareness of human needs and pointed the way for the Christian community's appreciation of the benefits available in modern medicine and therapy. (C.H.Li.)

CHURCH AND MINORITIES

The tendency to develop an identifiable Christian culture is apparent even where Christian minorities live in a non-Christian environment—*i.e.,* in an environment the life of which has been shaped and is characterized by a non-Christian religion. This is the case with most Christian churches in Asia and Africa.

In some countries Christian minorities have had to struggle for their existence and recognition, and there are cases of persecutions of Christians. On the other hand, in some cases the situation of Christian minorities is ideally suited to demonstrate to outsiders the peculiar style of life of a Christian culture. This is particularly advantageous for the church within a caste state, in which the church itself has developed into a caste, with special extrinsic characteristics in clothing and customs. An example of this phenomenon is the Mar Thoma Church of South India.

The problem of the coexistence of racially different Christian cultures

A special problem presents itself through the coexistence of racially different Christian cultures in racially mixed states. The influence of the Christian black churches, especially of Baptist denominations, has been thoroughly imprinted upon the culture of North American blacks. The churches themselves were founded through the missionary work of white Baptist churches but became independent of their mother churches or were established as autonomous churches within the framework of the Baptist denomination. A similar situation exists in South Africa, where white congregations and separate black congregations have been established within the white mission churches; independent messianic black churches have appeared outside the older organized congregations. In the 20th century much tension exists in this area.

On the one hand, the Christian Church has from the beginning urged the overcoming of racism. In the early church, racism was unknown; the Jewish synagogues allowed black proselytes. The first Jewish proselyte mentioned in the Acts of the Apostles was a governmental administrator from Ethiopia, who was baptized by the Apostle Philip. The early congregations in Alexandria included many Ethiopians and blacks. Among the evangelizing churches, the Portuguese Catholic mission in principle did not recognize differences between races—whoever was baptized became a "human being" and became a member not only of the Christian congregation but also of the Christian society and was allowed to marry another Christian of any race. In contrast to this practice, the Catholic mission of the Spaniards introduced the separation of races under the term *casticismo* (purity of the Castilian heritage) in the American mission regions and sometimes restricted marriage between Castilian Spanish immigrants and native Christians. Like the Portuguese in Africa and Brazil, the French Catholic mission in Canada and in the regions around the Great Lakes in North America did not prohibit marriage of whites with Indians but tolerated and even encouraged it during the 17th and 18th centuries.

Consequently, the Christian churches led in endeavours for racial integration, with the exception of those churches that maintained racial segregation from the beginning, in deference to theological arguments deduced from the "order of the creation" and "predestination." The latter was the case in some Reformed churches of the United States and of South Africa. On the other hand, the ideologically

and politically founded racial theory has been introduced into black churches in recent times. The demand for a black theology with a black Christ in its centre has been made and, just as much as a theologically and ideologically founded racial theory on the part of whites, aggravates the specifically Christian task of racial integration within the church.

The promise of recent liberation theologies such as black theology, Latin-American theology, and feminist theology is that of expanding awareness of the history and praxis of Christianity beyond the history of doctrines, the ideas of the elite, and the institutions that convey these ideas. Such reflection—which arises out of lived situations—reveals roles of the poor, the oppressed, and women that have too often been ignored and suppressed. These new orientations serve the church and the world not only by recalling hitherto unnoticed aspects of the past but also by strengthening peoples' awareness of their own causes.

CHURCH AND FAMILY

The Christian understanding of sexuality, marriage, and family has been strongly influenced by the Old Testament view of marriage as an institution primarily concerned with the establishment of a family, rather than sustaining the individual happiness of the marriage partners. Until the Reformation the patriarchal family structure not only had been preserved but also had been defended from all attacks by sectarian groups. In spite of this, a transformation occurred from the early days of Christianity.

This transformation is evident in the New Testament departure from the Hellenistic understanding of love. The classical understanding of love, expressed in the Platonic concept of eros, was opposed in the Christian community by the biblical understanding of love, agape. Although erotic love has frequently been understood primarily as sexual desire and passion, its classical religious and philosophical meaning was the idealistic desire to acquire the highest spiritual and intellectual good. The early Christian perception of eros as the most sublime form of egocentricity and self-assertion, the drive to acquire the divine itself, is reflected in the fact that the Greek New Testament does not use the word *erōs* but rather the relatively rare word *agapē*. *Agapē* was translated into Latin as *cāritās* and thus appears in English as "charity" and, later, "love." The Christian concept of love understood human mutuality and reciprocity within the context of God's self-giving love, which creates value in the person loved. "We love, because he first loved us. If any one says, 'I love God,' and hates his brother, he is a liar; for he who does not love his brother whom he has seen, cannot love God whom he has not seen. And this commandment we have from him, that he who loves God should love his brother also" (1 John 4:19–21). Love is presented as the greatest of the virtues (1 Corinthians 13:13) as well as a commandment. The Christian community understood faith active in love primarily in terms of voluntary obedience rather than emotion and applied this understanding to every aspect of life, including sexuality, marriage, and family.

The tendency to spiritualize and individualize marriage. Christianity has contributed to a spiritualization of marriage and family life, to a personal deepening of the relations between marriage partners and between parents and children, as well as between heads of households and domestic servants in large families. Marriage can be called the most intimate form in which the fellowship of believers in Christ is realized. In the early church, children were included in this fellowship. They were baptized when their parents were baptized, took part in the worship life of the congregation, and received Holy Communion with their parents. The Eastern Orthodox Church still practices as part of the eucharistic rite Jesus' teaching, "Let the children come to me, and do not hinder them." During the first decades of the church, congregational meetings took place in the homes of Christian families. The family became the archetype of the church. Paul called the members of his congregation in Ephesus "members of the household of God" (Ephesians 2:19).

Deepening of the relations between marriage partners

In the early church the Christian foundation of marriage—in the participation of Christians in the body of Christ—postulated a generous interpretation of the fellowship between a Christian and a pagan marriage partner: the pagan one is saved with the Christian one "for the unbelieving husband is consecrated through his wife, and the unbelieving wife is consecrated through her husband"; even the children from such a marriage in which at least one partner belongs to the body of Christ "are holy" (1 Corinthians 7:14). If the pagan partner, however, does not want to sustain the marriage relationship with a Christian partner under any circumstances, the Christian partner should grant him a divorce.

New Testament views on marriage

Jesus himself based his parables of the Kingdom of God on the idea of love between a bride and groom and frequently used parables of a wedding that describe the messianic meal as a wedding feast. In Revelation the glorious finale of salvation history is depicted as the wedding of the Lamb with the bride, as the beginning of the meal of the chosen ones with the Messiah–Son of man (Revelation 19:9: "Blessed are those who are invited to the marriage supper of the Lamb"). The wedding character of the eucharistic meal is also expressed in the liturgy of the early church. It is deepened through the specifically Christian belief that understands the word of the creation story in Genesis "and they become one flesh" as indicative of the oneness of Christ, the head, with the congregation as his body. With this in mind the Christian demand of monogamy becomes understandable.

In the so-called ethical lists in the Letter of Paul to the Colossians and in 1 Peter, Christian marriage is distinguished from the marriage practices of its pagan environment by its stricter ethical demands. The rules concern the mutual relationship of the marriage partners, fidelity, as well as attitudes toward children and slaves of the house.

The position of women

Christianity did not bring a revolutionary social change to the position of women, but it made possible a new position in the family and congregation. In the world of the early church, women were held in very low esteem, and this was the basis for divorce practices that put women practically at men's complete disposal. With the prohibition of divorce, Jesus himself did away with this low estimation of women. The decisive turning point came in connection with the understanding of Christ and of the Holy Spirit. Even the Jewish view of the patriarchal position of man was substituted by Paul with a new spiritual interpretation of marriage. "There is neither male nor female; for you are all one in Christ Jesus" (Galatians 3:28). In fulfillment of the prophecy in Joel 3:1, the Holy Spirit was poured out over the female disciples of Jesus, as well.

This created a complete change in the position of women in the congregation: in the synagogue the women were inactive participants in the worship service and sat veiled on the women's side, usually separated from the rest by an opaque lattice. In the Christian congregation, however, women appeared as members with full rights, who used their charismatic gifts within the congregation. In the letters of Paul, women are mentioned as Christians of full value. Paul addresses Prisca (Priscilla) in Romans 16:3 as his fellow worker. The four daughters of Philip were active as prophets in the congregation. Peter, in a sermon on Pentecost, spoke about men and women as recipients of the gifts of the Holy Spirit: "Your sons and your daughters shall prophesy" (Acts 2:17). Pagan critics of the church, such as Porphyry (*c.* 234–*c.* 305), maintained that the church was ruled by women. During the periods of Christian persecution, women as well as men showed great courage in their suffering. The fact that they were spontaneously honoured as martyrs demonstrates their well-known active roles in the congregations. In this, representatives of patriarchal, rabbinic, and synagogic traditions within the Christian Church saw a danger to congregational constitutions. Paul, on the one hand, included women in his instruction, "Do not quench the Spirit" (1 Thessalonians 5:19), but, on the other hand, carried over the rule of the synagogue into the Christian congregation that "women should keep silence in the churches" (1 Corinthians 14:34). In the 20th century the Roman Catholic Church still refuses to ordain women as priests.

The tendency toward asceticism. The proponents of an ascetic theology demanded exclusiveness of devotion

The demand for celibacy

by faithful Christians to Christ and deduced from it the demand of celibacy. This is found in arguments for the monastic life and in the Roman Catholic view of the priesthood. The radical-ascetic interpretation stands in constant tension with the positive understanding of Christian marriage. This tension has led to seemingly unsolvable conflicts and to numerous compromises in the history of Christianity. Without doubt, from the beginning a strong ascetic tendency dominant in Christianity was emphatically directed against the oversexualization of the Hellenistic culture, against the decay of marital life in the Hellenistic world, against the spreading of pederasty and its social recognition and open institutionalization, against cultic and non-cultic prostitution, and against the more or less tolerated sodomy that was excused with pagan mythology.

In the light of the beginning Kingdom of God, marriage was understood as an order of the old passing eon, which would not exist in the approaching new age. The risen ones will "neither marry nor are given in marriage, but are like angels in heaven" (Mark 12:25). Similarly, Paul understood marriage in the light of the coming Kingdom of God: "The appointed time has grown very short; from now on, let those who have wives live as though they had none . . . for the form of this world is passing away" (1 Corinthians 7:29–31). In view of the proximity of the Kingdom of God, it was considered not worthwhile to marry; and marriage was seen to involve unnecessary troubles: "I want you to be free from anxieties" (1 Corinthians 7:32). Therefore, the unmarried, the widowers, and widows "do better" if they do not marry, if they remain single. But according to this point of view marriage was recommended to those who "cannot exercise self-control . . . for it is better to marry than to be aflame with passion" (1 Corinthians 7:9). With the waning of the eschatological expectation that formed the original context for the Pauline views on marriage, his writings were interpreted ascetically. While these texts have been used alone in the course of church history, however, they do not stand alone in the New Testament, which also portrays marriage feasts as joyous occasions and sexual intercourse between spouses as good and holy (Ephesians 5:25–33).

The demonization of sex

A demonization of sex in general occurred in dualistic Gnostic movements. This was particularly apparent in the ascetic branches of Gnosticism and especially in Manichaeism (an Iranian dualistic religion). The conscious renunciation by Christians of the customs of their oversexualized pagan environment supported these tendencies. Their motives are apparent in the biographies and letters of the great ascetics, such as Anthony and Jerome. Within the Roman Catholic Church the tension between the Christian high esteem and the ascetic devaluation of marriage led to a constantly challenged compromise: celibacy was demanded not only of ascetics and monks but also more and more of members of the clergy as a duty of their office.

The Reformation rejected clerical celibacy because it removed men and women from service to the neighbour, contravened the divine order of marriage and the family, and denied the goodness of sexuality. Luther viewed marriage as not merely the legitimation of sexual fulfillment but as above all the context for creating a new awareness of human community through the mutuality and companionship of spouses and family. The demand that priests and monks observe celibacy was not fully accepted in the East. The early church, and following it the Eastern Orthodox Church, decided on a compromise at the Council of Nicaea (325): the lower clergy, including the archimandrite, would be allowed to enter matrimony before receiving the higher degrees of ordination; of the higher clergy—*i.e.,* bishops—celibacy would be demanded. This solution has saved the Eastern Orthodox from a permanent fight for the demand of celibacy for all clergymen, but it has resulted in a grave separation of the clergy into a white (celibate) and a black (married) clergy, which led to severe disagreements in times of crisis within Orthodoxy.

Problem of birth control

The early Christian community's attitude to birth control was formed partly in reaction against secular attitudes of indifference to sexual exploitation and infanticide and partly against the Gnostic denigration of the material world and consequent hostility to procreation. In upholding its faith in the goodness of creation, sexuality, marriage, and family, the early church was also influenced by the prevalent Stoic philosophy, which emphasized procreation as the rational purpose in marriage.

The question of birth control entered a new phase through the invention and mass distribution of technical contraceptive devices on the one hand and through the appearance of a new attitude toward sexual questions on the other. In this situation an obvious differentiation of interpretation developed within Christianity: with a few exceptions—*e.g.,* the Mormons—the Protestant churches accepted birth control in terms of a Christian social ethic. In contrast, the Roman Catholic Church, in the encyclical of Pius XI *Casti Connubii* (1930) and in the encyclical of Paul VI *Humanae Vitae* (1968), completely rejected any kind of contraception. Modern economic and population concerns in connection with improved medical care and social and technological progress have once again confronted the Christian community with the issue of contraception.

CHURCH AND THE INDIVIDUAL

Christianity received the main commandment of its ethic from the Old Testament: "You shall love your neighbour as yourself" (Leviticus 19:18), but Jesus filled this commandment with a new, twofold meaning. First, he closely connected the commandment "love your neighbour" with the commandment to love God. In the dispute with the scribes described in Matthew, chapter 22, he quoted the commandment of Deuteronomy 6:5, "You shall love the Lord your God with all your heart, and with all your soul, and with all your might." He spoke of the commandment of love for neighbour, however, as being equal to it. With that he lifted it to the same level as the highest and greatest commandment, the commandment to love God. In the Gospel According to Luke, both commandments have grown together into one single pronouncement with the addition: "Do this, and you will live." Second, the commandment received a new content in view of God and in view of the neighbour through the relationship of the believer with Christ. Love of God and love of the neighbour is possible because the Son proclaims the Gospel of the Father and brings to it reality and credibility through his life, death, and Resurrection. Based on this connection of the Christian commandment of love with the understanding of Christ's person and work, the demand of love for the neighbour appears as a new commandment: "A new commandment I give to you, that you love one another; even as I have loved you, that you also love one another" (John 13:34). The love for each other is supposed to characterize the disciples: "By this all men will know that you are my disciples, if you have love for one another" (John 13:35).

Love as a new commandment

This is an ethic that does not base its norms on social, biologic, psychological, physiological, intellectual, or educational differences and levels but on an understanding and treatment of human beings as created in the image of God. Furthermore, the ethic does not deal with humanity in an abstract sense but with the actual neighbour. The Christian ethic understands the individual always as a neighbour in Christ.

The new element of the Christian ethic is the founding of the individual ethic in a corporate ethic, in the understanding of the fellowship of Christians as the body of Christ. The individual believer is not understood as a separate individual who has found a new spiritual and moral relationship with God but as a "living stone" (1 Peter 2:4), as a living cell in the body of Christ in which the powers of the Kingdom of God are already working.

The realization of Christian love leads to the peculiar exchange of gifts and suffering, of exaltation and humiliations, of defeat and victory; the individual is able through personal sacrifice and suffering to contribute to the development of the whole. In this basic idea of the fellowship of believers as the body of Christ, all forms of ecclesiastical, political, and social communities of Christianity are founded. It also has influenced numerous secularized

forms of Christian society, even among those that have forgotten or denied their Christian origins.

From the beginning, the commandment contains a certain tension concerning the answer to the question: Does it refer only to "the disciples," that is, fellow Christians, or to "all"? The practice of love of neighbour within the inner circle of the disciples was a conspicuous characteristic of the young church. Pagans said: "Look, how they love each other" (Justin). Christian congregations and, above all, small fellowships and sects have stood out throughout the centuries because of the fact that within their communities love of the neighbour was highly developed in the form of personal pastoral care, social welfare, and help in all situations of life.

The Christian commandment of love, however, has never been limited to fellow Christians. On the contrary, the new factor in the Christian ethic was that it crossed all social and religious barriers and saw a neighbour in every suffering human being. Characteristically, Jesus himself explicated his understanding of the practical implications of the commandment of love in the parable of the Good Samaritan, a non-Jew who followed the commandment of love and helped a person in need whom the believing wanderers—a priest and a Levite—had chosen to ignore (Luke 10:29–37). A demand in the Letter of James, that the "royal law" of neighbourly love has to be fulfilled without "partiality" (James 2:9), points to its universal validity.

The universalism of the Christian command to love is most strongly expressed in its demand to love one's enemies. Jesus himself emphasized this with these words: "Love your enemies and pray for those who persecute you, so that you may be sons of your Father who is in heaven; for he makes his sun rise on the evil and on the good, and sends rain on the just and on the unjust" (Matthew 5:44–45). According to this understanding, love of the enemy is the immediate emission of God's love, which includes God's friends and God's enemies.

The Reformation revitalized a personal sense of Christian responsibility by anchoring it in the free forgiveness of sins. Luther summarized this in "The Freedom of a Christian Man" (1520): "A Christian is a perfectly free lord of all, subject to none. A Christian is a perfectly dutiful servant of all, subject to all." The second sentence expressed the theme of Christian vocation developed by Luther and Calvin. While the medieval church understood vocation in terms of the specific religious calling of priesthood and monastery, the Reformers expanded the concept of vocation to all Christians and to everyday responsibility for the neighbour and for the world. The Reformers emphasized that Christian service is not limited to a narrow religious sphere of life but finds means to help others in the everyday relationships of family, marriage, work, and politics.

Personal and social ethics

Later Protestantism under the influence of Pietism and Romanticism restricted the social and communal orientation of the Reformers to a more individualistic orientation. This met, however, with an energetic counterattack from the circles of the Free churches (*e.g.*, Baptists and Methodists) who supported the social task of Christian ethic (mainly through the Social Gospel of the American theologian Walter Rauschenbusch, who attempted to change social institutions and bring about a Kingdom of God), which spread through the whole church, penetrating the area of Christian mission. Love rooted in faith has continued to play an important role in the 20th century in the struggle between Christianity and all ideologies, such as Fascism, Communism, and jingoistic nationalisms.

(E.W.B./C.H.Li.)

Christian missions

In the late 20th century about one-third of the world's people claimed the Christian faith. Christians thus constituted the world's largest religious community and embraced remarkable diversity, with churches in every nation. Christianity's demographic and dynamic centre had shifted from its Western base to Latin America, Africa, Asia, and the Pacific region, where more than half the world's Christians lived. This trend steadily accelerated as the church declined in Europe. The tangibly real universal church represented a new phenomenon in the history of religions. This was the fruit of mission.

BIBLICAL FOUNDATIONS

The word mission (Latin: *missiō*), as a translation of the Greek *apostolē*, "a sending," appears only once in the English New Testament (Galatians 2:8). An apostle (*apostolos*) is one commissioned and sent to fulfill a special purpose. The roots of mission, Christians have believed, lie in God's active outreach to humanity in history—as a call to those able to fulfill the divine purpose, among them Abraham, Moses, Jonah, and Paul. The New Testament designated Jesus as God's apostle (Hebrews 3:1). Jesus' prayer in the Gospel According to John includes the words "As thou didst send me into the world, so I have sent them into the world. . . . [I pray also] for those who believe in me through their word, that they may all be one . . . so that the world may believe that thou hast sent me" (John 17:18, 20–21).

The ground for mission appeared early in the Old Testament in God's concern for all nations (Genesis, chapters 10 [the "Table of Nations"] and 11) and the calling of Abraham—implicitly of Israel (Genesis 12:1–3). The Jews acknowledged God's sovereignty over all the world's peoples but believed God had chosen Israel to be the sign to all nations of the divine will and purpose (compare the "Covenant on Sinai," Exodus 19:5–6). Echoing throughout the Old Testament, this theme found its clearest voice in Isaiah: "I have given you as a covenant to the people, a light to the nations" (42:6); and in God's universal task for Israel as servant to the nations: "I will give you as a light to the nations, that my salvation may reach to the end of the earth" (49:6).

The Maccabean wars filled the Jews with fervent hope for a powerful messiah to bring political triumph to a suffering Israel. Jesus Christ, professed by his followers as Messiah in the role of suffering servant presented in Isaiah (52:13–53:12), found widespread rejection among his people. Yet those from Israel who confessed faith in him as Messiah and Lord saw in Christ's Incarnation, death, and Resurrection God's decisive entry into history—an act in continuity with God's incursions in Israel's past. In that reality they and their successors viewed the Old and New Testaments (or "Covenants") as inseparably united and mutually interdependent. The church was born and grew as the covenanted instrument of and witness to God's mission (*missio Dei*), the human agency of God's outreach to all the peoples of the world.

The Great Commission

The "Great Commission" of Jesus declares: "Go therefore and make disciples of all nations, baptizing them in the name of the Father and of the Son and of the Holy Spirit, teaching them to observe all that I have commanded you; and lo, I am with you always, to the close of the age" (Matthew 28:19–20; compare Mark 16:15, Luke 24:47, John 20:21–22, and Acts 1:8). Not an isolated command, it re-expressed, in Christian perspective, the obedience of a servant in universal witness to the mission of God as declared in the Old and New Covenants.

THE HISTORY OF CHRISTIAN MISSIONS

The Christian mission, the church, and Christianity—each distinguishable, but inseparably related—have experienced across 20 centuries of world history four major transitions.

First transition, to AD 500. Born on Jewish soil but quickly emerging from Palestine to cover the rim of the Mediterranean world, the new missionary faith made its first major transition. The Apostle Paul became the missionary to the Gentile world. With help from Barnabas and a local network of coworkers, many of them women, he evangelized Asia Minor and southern Greece and eventually reached Rome. When Rome destroyed Jerusalem in AD 70, Antioch became Christianity's centre in the Eastern Empire, and mission became one of Gentiles to Gentiles. Thus began the transition.

Dominated politically by the Roman Empire, the new religion benefited from one unifying factor in the Greco-Roman world: common, or koine, Greek provided its lingua franca. Alexandrian Jews had already translated (250 BCE) the Hebrew Bible into koine Greek for dis-

persed Greek-speaking Jews. The New Testament writers also wrote in koine Greek. In that largely literate empire early Christians used and widely distributed the Hebrew Scriptures.

Channels of growth

Several factors brought growth to the faith. From the beginning laypeople—women and men—conducted the largest part of mission. Congregations grew in homes used as churches. Although it was owned by the husband, inside the house the wife was its mistress, and thousands of women opened their homes to newly forming churches. Most evangelization occurred in the daily routine as men and women shared their faith with others. Christianity's monotheism, morality, assurance of eternal life with God, and ancient Scriptures attracted many to the faith.

From the empire-wide occasions of emperor worship, Rome had exempted only the Jews. Christians also refused to engage in emperor worship. Rome declared their faith an illegal religion, and persecutions ensued. In the persecutions so many Christians had borne powerful witness (Greek: *martyria*) that the word martyr quickly evolved into its current meaning. Christian faith—not least that of young women such as Blandina, Perpetua, and Felicity—had made an impact, and many who beheld that witness became Christian. In 313 when the new emperor, Constantine, declared the persecutions ended, Christians probably constituted 10 percent of the empire's population.

Christians daily encountered members of other religions—the mysteries, Gnosticism, and philosophical cults. In the 2nd and 3rd centuries external and internal pressures drove the young church to strengthen itself through creating a structured ministry, formulating beliefs in creeds, and producing a canon of Scripture. That process transformed a movement into a young religious institution. The major thrust of the pre-Constantinian church-mission sprang from the conviction that Christians and congregations were fulfilling a mission and ministry begun in Jesus Christ. Baptism provided induction into the vibrant company of "God's own people" (1 Peter 2:9–10).

By 315 many who saw advantage in belonging to Constantine's new imperial faith poured into the churches. The result was striking: small congregations of convinced Christians serving God's outreach in the world became large churches with many nominal members whose instruction and needs had to be met within the new churches. As multitudes entered the churches, the need for outreach to others was much reduced, and most churches shifted from an outward thrust to an inward focus upon themselves. Mission and service became the province of priests, deacons, and, increasingly, monks. This Constantinian inversion helped shape the churches of Christendom.

Mission outside the empire

At the same time, mission beyond the frontiers of the empire continued. Ulfilas (*c.* 311–*c.* 382), Arian apostle to the Goths, translated the Bible into their tongue. Martin of Tours (*c.* 316–397) served in Gaul, and Patrick (*c.* 389–*c.* 461) laboured in Ireland. In Malabar, South India, a church of ancient tradition, demonstrably present since the 3rd century, held the Apostle Thomas to be its founder. Frumentius (d. *c.* 380) from Tyre evangelized in Ethiopia and became the first patriarch of its church. In the 5th century Nestorians pushed into Central Asia and began a mission that eventually reached the capital of China.

In 410 Rome fell to the barbarians, and by 476 the entire Western Roman Empire had collapsed. In the eyes of many members of the still-pagan Roman nobility, the rise of the Christian faith in the Mediterranean world had caused the empire's downfall. Yet where Constantine had built his capital, Constantinople—the "second Rome"—the Eastern Empire continued.

In its first 500 years Christianity achieved remarkable missionary and theological acculturation. Through the first four ecumenical councils (325–451), and in the Nicene Creed (on the Trinity) and Definition of Chalcedon (on Christology), the church had stated its faith with meaning for the Greek and Latin worlds.

By the close of the period Jerome's Latin translation of the Bible, the Vulgate, had appeared. Church and state already were locked in uneasy embrace. The first great transition of the Christian mission—from Judaic Palestine to the Mediterranean world—had ended.

Second transition, to AD 1500. Rome's urban and literate world quickly disappeared under the barbarians' westward onslaught. These rough conquerors filled Europe's rural lands; however, they recognized in missionary monks the bearers of a new faith and preservers of a higher civilization. The monks instructed them in the faith and in statecraft. The mission thrust of these monks contrasted sharply with that of the tiny persecuted church in the first three centuries. Then, except for the conversions of the city-state of Edessa, in AD 200, and Armenia, declared a Christian nation in AD 300, people joined the new faith individually. In this second transition whole peoples followed their sovereigns into the new faith.

Christianity expanded in the Byzantine Empire, most notably in Russia, but it experienced a widening breach, and a split of the Eastern and Western churches occurred in 1054. Yet the major result of this 1,000-year mission was the creation of European civilization. Its emergence marked the second great transition of the faith.

Western mission. The medieval mission began in 496 with the baptism of Clovis, king of the Franks, and his soldiers. Baptized by a Catholic bishop rather than an Arian one (through the influence of Clovis' Catholic wife), they helped to turn the tide against the Arians.

Celtic missions

Irish Celtic Christianity differed from that on the Continent. It was organized into communalized groups under an abbot and nurtured intense missionary conviction and outreach. It did not recognize Rome's authority. The abbot Columba (*c.* 521–597) built a monastery on Iona, off Scotland's western coast, as a base for mission to Scotland and northern England. From it Aidan (d. 651) traveled to Lindisfarne, off England's northern coast, where he and a successor, Cuthbert (634/635–687), led in evangelizing in Northumbria. Moving southward, the Celtic monks might have evangelized all of Britain, but midway they met Roman missionaries. Other Celtic *peregrini,* or "wanderers," evangelized on the Continent.

Papal mission. Pope Gregory I the Great (reigned 590–604), who possessed the mind of both a statesman and a theologian, operated as a Roman emperor and greatly magnified papal power and temporal involvement. In 596 he launched, through Augustine of Canterbury, a mission to England based on gradualism and accommodation—the first papally sponsored mission. For the next 1,000 years Roman missions operated with the pope's direction, the king's support, and the monks' services.

Augustine's missionaries reached England's southern coast in 597. King Aethelberht of Kent and his wife, Bertha, a Christian, enabled them to make their base at Canterbury. Within the year the King and 10,000 subjects had received baptism. Roman missionaries moving northward met the Celts, and at the Synod of Whitby in 664 the Celts accepted Roman jurisdiction and patterns.

Inspired by Irish missionary enthusiasm, the English Christians began a 500-year mission across northern Europe and finally into Scandinavia. Outstanding in this effort were Willibrord (658?–739), "Apostle to the Frisians" (Friesland, Holland, and Belgium), and Wynfrid, renamed Boniface (*c.* 675–754), one of the greatest of all Roman missionaries. In central and southern Germany Boniface established Benedictine monasteries for evangelization. With full papal trust and Carolingian support he strengthened and reformed the Frankish church.

Boniface also saw the need for women in mission. From England he recruited Lioba (d. 782) and entrusted her with developing Benedictine monasteries for women. Despite her outstanding and unique achievements, with her death that movement ended, and Roman Catholic women reentered mission service only in the 19th century. But the Christian wives of pagan kings, who led their husbands into the faith and through them hastened the Christianizing of whole peoples, also contributed to its spread.

In Rome on Christmas Day, AD 800, Pope Leo III crowned Charlemagne (d. 814) Holy Roman emperor. Leo thus demonstrated the primacy of papal power over temporal rulers and symbolized the growing gulf between the Eastern and Western churches. Charlemagne's missionary zeal and political goals fused. Saxons in his territories faced a choice: become Christian or die.

Mission to eastern Europe and Scandinavia

From the Holy Roman Empire, Catholic outreach into Bohemia took root under King Wenceslas I (*c.* 907–929), with evangelization complete by about AD 1000. In Poland, Mieszko I, under the influence of his wife, accepted baptism in 966 or 967. His reign saw the beginning of the evangelization of the country, which continued under his able son, Boleslav. In 955 the Holy Roman emperor Otto I defeated the Magyars and brought them to Christian faith. Later, the country's first king, Stephen (reigned 1000–38), made Hungary a Christian land.

Early attempts at evangelization in Denmark and Sweden were made by a German monk, Ansgar (801–865). Canute (d. 1035), Danish king of England, of Denmark, and of Norway, was probably raised as a Christian and determined that Denmark should become a Christian country. The archbishop of Canterbury consecrated bishops for him, and he saw his goal realized before he died. Olaf I Tryggvason (reigned 995–*c.* 1000) was baptized by a Christian hermit, returned to Norway and was accepted as king, and sought to make his realm Christian—a task completed by King Olaf II Haraldsson (reigned 1016–30), later St. Olaf. Olaf I also presented Christianity to a receptive Iceland. Leif Eriksson took the faith to Greenland's Viking settlers, who quickly accepted it. After several efforts Sweden became Christian during the reign of Sverker (*c.* 1130–56). Sweden's Eric IX controlled Finland and in 1155 required the Finns to be baptized, but only in 1291, with the appointment of Magnus, the first Finnish bishop, was evangelization completed.

Eastern and Nestorian missions. Removal of the empire's capital from Rome to Constantinople, the "second Rome," in 330 greatly strengthened the temporal power of the bishop of Rome. In the Byzantine Empire the patriarch of Constantinople remained under the political control of the Christian emperor. Cultural, political, philosophical, and theological differences strained relations between the two cities. Rome demanded Latin as the one ecclesiastical language, but Constantinople encouraged national languages for the liturgy and emphasized translation of the Scriptures. In 1054 leaders of the two bodies excommunicated each other.

One reflection of growing difficulties lay in counterclaims to pursue mission in and hold the allegiance of border areas between the two jurisdictions. Rostislav of Great Moravia sought help from the Emperor, who (presumably through the Patriarch) in about 862 sent two brothers, Constantine (later called Cyril; *c.* 827–869) and Methodius (*c.* 825–884), from Constantinople to Moravia. They provided Scriptures and liturgy in the mother tongue of each people evangelized. They also trained others in their methods—a major factor in winning Bulgaria.

Constantinople's greatest mission outreach was to areas that later became Russia. In the 10th century the Scandinavian Rus controlled the areas around Kiev. Undoubtedly influenced by his Christian grandmother Olga and by a proposed marriage alliance with the Byzantine imperial family, Vladimir I (*c.* 956–1015) of Kiev, from among several options, chose the Byzantine rite. Baptized in 988, he led the Kievans to Christianity. His son Yaroslav encouraged translations and built monasteries.

From 1240, and continuing for 200 years, the Mongol Golden Horde was suzerain over Russia but generally allowed freedom to the church. For Russians the church proved to be the one means through which they could express national unity. They moved the metropolitanate from Kiev to Moscow, and their church became and remained the largest of the Orthodox bodies, protector and leader for the others. In 1453 Constantinople fell to the Ottoman Turks. Moscow became "the third Rome" and accepted for itself the mystique, dynamism, and messianic destiny of the first Rome—a reality essential to understanding Russian Orthodoxy and nationalism.

Early missions to China

East of the Euphrates River, Nestorians and Jacobites maintained headquarters in Persia for eastern outreach. The more numerous Nestorians developed a far-flung mission network throughout Central Asia. The Persian bishop A-lo-pen reached China's capital, Ch'ang-an (modern Sian), in 635 and founded monasteries to spread the Christian faith. By the end of the T'ang dynasty (618–907), however, the Nestorian community had disappeared.

In 1289 the Pope—responding to a request made 20 years earlier by Kublai Khan for 100 Christian scholars to be brought by the Polo brothers—sent one Franciscan, Giovanni da Montecorvino (1247–1328). He reached Khanbaliq (Peking) in 1294 and launched a small but successful mission. In 1342 Giovanni dei Marignolli arrived with 32 other missionaries, but their work flourished for less than 25 years. The succeeding Ming dynasty excluded foreigners. Twice Christianity had entered and disappeared from China.

The rise of Islām. Between Muḥammad's death in 632 and the defeat of Muslim forces at Poitiers by Charles Martel's Franks in 732, Arab Muslims had taken the Middle East and Egypt, then swept across North Africa, turned northward through Spain, and ventured briefly into southwestern France. Within a century Islām had eliminated more than half of Christendom.

Encouraged by the papacy, the Iberian reconquest (742–1492) became a crusade against Islām and fused an Iberian Catholicism that Spain and Portugal later transplanted around the globe. In the late 20th century its members represented more than half the world's Roman Catholics. The Crusades (1095–1396) produced among many Christians an adversarial approach to those of other faiths. Ramon Llull (*c.* 1235–1316) pursued a different way. He studied Arabic and sought through dialogue and reason the conversion of Muslims and Jews.

As a result of the second great transition the faith of the Mediterranean world had become that of all Europe and had largely created its civilization. Christendom had lost half its members to Islām, but Europe had become the new centre of the Christian faith.

Third transition, to AD 1950. By 1500 Europe was bursting with new energy and achievement, and from it Christianity spread worldwide. Iberian monks in the 16th century spanned the globe, and 300 years later Protestant missionaries did the same.

Roman Catholic mission, 1500–1950. With Europe cut off from Asia by the Muslims, Portugal's Prince Henry the Navigator (1394–1460) launched exploratory voyages along the western coast of Africa. In 1498 Vasco da Gama reached India; others pushed to Asia's eastern limits. Papal grants in 1454 and 1456 gave Henry all lands, power over the missionary bishops therein, and trading rights south of the Tropic of Cancer. An early Portuguese mission to the Congo produced an African bishop, but the church quickly disappeared. Other efforts on both African coasts also were unsuccessful.

Spain sought a route to India through Columbus' westward voyages. In 1494 a papal grant gave Spain everything west of 47° W longitude (eastern Brazil). Under royal patronage (*patronato real,* or *padroado*), monarchs of both nations accepted responsibility for evangelizing the newly found peoples. Franciscans, Dominicans, Augustinians, and, from 1542, Jesuits staffed the resulting missions.

By 1600 France was becoming the third great imperial Roman Catholic power and was also deeply involved in mission. At the same time England, Holland, and Denmark—all Protestant—began an imperial thrust that challenged the Roman Catholic powers in their own territories.

When the Europeans arrived in the Americas, the Indian population south of the Rio Grande numbered some 35,000,000, but in North America there were at most 1,200,000 Indians—a marked difference. The great majority of European males entering Latin America were unmarried and quickly produced a mestizo, or mixed, population. European settlers, who expected to instruct the Indians in the faith and protect them, gained their labour. The Indians were used widely as slaves and often were treated cruelly. Bartolomé de Las Casas (1474–1566) championed their cause but, ironically, favoured increasing the already growing number of African slaves.

Despite its weaknesses, the Roman Catholic mission gained vast numbers. Although later modified, a 1555 decree which held that Indians, mestizos, and mulattos could not be ordained proved ruinous. Never inspired to produce their own clergy, the new Christians became dependent upon European clergy.

Franciscans and Dominicans traveled widely and built mission churches. The most notable development—used widely but most fully developed by Jesuits in Paraguay—was the appearance of the *reducciones*. In these mission-operated villages Indians were instructed in the faith, taught to develop trades, and protected from the Europeans. Despite good intentions this environment did not produce strong Christians. The movement dissolved when the Jesuits were disbanded in 1773.

Much of the evangelization appeared to be an integral part of military conquest. Yet in whatever way Indians and mestizos intermingled past beliefs and practices with their Christian faith, the majority thought of themselves as Roman Catholic.

Evangelization in French North America followed a somewhat different course. In 1534 Jacques Cartier claimed New France (Canada) for his homeland. A century later French missionaries began to enter the territory. In their work these missionaries sought to reshape Indian life as little as possible.

Efforts of St. Francis Xavier

In Asia, chiefly through the Jesuits, some of the most productive missions appeared. Under a papal commission the Jesuit missionary Francis Xavier (1506–52) reached Goa in 1542. He established Christian communities in India, built a college in Goa for training priests, began a prospering mission in Japan, and died off the coast of China while hoping to enter that land.

By 1600 there were about 300,000 Christians in Japan. Christianity was proscribed, thousands were martyred, and the Japanese sealed themselves off from the West.

China also was closed to foreigners, but the Italian Jesuit missionary Matteo Ricci (1552–1610) arrived in 1582 and eventually reached the capital. His efforts brought success, and other Jesuits followed. An edict of toleration was proclaimed in 1692. Ricci's conviction that the honouring of ancestors and Confucius was a social rite that could be accommodated within the church produced the Chinese Rites Controversy (1634–1742). It brought bitter opposition from Dominicans and Franciscans. Attempts at papal intervention at the beginning of the 18th century angered the Emperor. The Chinese forced missionaries to leave the country and persecuted Christians. Yet by 1800 some 250,000 remained, and since the 16th century the church has been continuously present in China.

In India Jesuits were welcomed to the court during the reign of Mughal emperor Akbar (1556–1605). The noted Jesuit Roberto de Nobili (1577–1656) sought points of agreement between Hinduism and Christianity as a means of evangelization, but this caused difficulty with the church. The missionaries also worked among India's existing Christian communities. In 1599 the Roman Catholic Church brought the South Indian Christians (Nestorians) into its fold, but in 1653 about 40 percent of the Syrian, or Thomas, Christians revolted and linked themselves with the Jacobites. Nevertheless, the Roman Catholics retained a solid base of Christians on which to build.

To provide knowledgeable oversight and to coordinate policy, in 1622 Pope Gregory XV established the Sacred Congregation for the Propagation of the Faith (Propaganda Fide), or the Propaganda. It provided a library for research and a school for training priests and missionaries, assigned territories, and directed ecclesiastical matters overseas. The Foreign Missionary Society of Paris (1663), directed exclusively toward outreach to non-Christian peoples, sought to produce rapidly an indigenous secular clergy (*i.e.*, one not bound to a religious order), and focused its efforts on Vietnam, Cambodia, Laos, and Thailand.

With the suppression of the Jesuits (1773–1814) and the decline of Spanish and Portuguese influence, Roman Catholic missions found themselves at low ebb, but French and other European missionaries steadily took up the slack. Between 1800 and 1950 new vigour paralleled that seen in Protestantism and brought new orders—such as the Society of the Divine Word (1875) and the Catholic Foreign Missionary Society of North America (1911) of Maryknoll fathers and sisters—and voluntary societies to promote and support missions. The missionary force remained overwhelmingly European.

Protestant missions, 1500–1950. Protestant missions emerged some 275 years after Martin Luther launched the Reformation in 1517. Reasons for the delay included Protestantism's thorough rejection of the theocratic and universal claims of the papacy and its rationale for papal mission. It also vigorously rejected monasticism and lacked the structure for mission that monasticism had supplied. Some Protestants—especially the Anabaptist but also other prophetic voices, including Adrian Saravia (1531–1613) and Justinian von Welz (1621–68)—called for mission but were scarcely heard.

Protestant expansion through colonization

Protestants began to expand overseas through migration, notably to North America. To minister to the colonists' needs, individual Anglicans formed the Society for Promoting Christian Knowledge (SPCK; 1698) and the Society for the Propagation of the Gospel in Foreign Parts (SPG; 1701), whose chaplains were also to spread the Gospel among non-Christians. The Dutch East India Company trained ministers in Leiden to serve their employees in Indonesia and Ceylon (Sri Lanka), but they were also encouraged to catechize and baptize local people.

European colonization of North America aroused interest in the American Indians, and the Virginia and Massachusetts charters enjoined their conversion. The mission of John Eliot (1604–90) to the Pequot Iroquois and that of the Thomas Mayhew family encouraged formation of supporting societies in Britain.

The German Lutheran Pietists were the first Protestant group to launch church-supported continuing missions from the Continent. Philipp Jakob Spener (1635–1705) and August Hermann Francke (1663–1727) at the Pietists' University of Halle trained Bartholomäus Ziegenbalg (1683–1719) and Heinrich Plütschau (1678–1747). From 1706 they served the Danish mission of King Frederick IV at Tranquebar, in South India. Also trained at Halle, Nikolaus Ludwig, Count von Zinzendorf (1700–60), received Moravian refugees at his Herrnhut estate and in 1732 molded them into a missionary church. Their small, self-supporting communities spread from Greenland to South Africa.

William Carey's *Enquiry into the Obligations of Christians, to Use Means for the Conversion of the Heathens* (1792) became the "charter" for Protestant missions and produced the Baptist Missionary Society. In 1793 Carey went to India. His first letter to an England stirred by the Evangelical Revival resulted in the formation of the London Missionary Society (1795). The Scottish Missionary Society (1796) and the Netherlands Missionary Society (1797) soon appeared, Anglican evangelicals organized the Church Missionary Society (1799), and many others followed. Like the SPCK and SPG, they were founded not by churches but as autonomous societies supported chiefly by denominational constituencies. Similarly, in Europe these organizations were usually created geographically—such as the Basel (1815), Berlin (1824), and Leipzig (1836) societies.

With separation of church and state in the United States, American churches made plain that mission was the responsibility of each Christian. Most denominations developed their own boards or societies. The American Board of Commissioners for Foreign Missions (1810) was the first, and the pattern of denominational societies spread.

Until 1890 American Protestant missions centred on the new immigrants and those following the westward-moving frontier, but from 1890 they turned their attention to areas abroad. In 20th-century "overseas" missions, English-speaking participants have represented from 80 to 89 percent, and North Americans about 67 percent, of all Protestant missionaries.

Women in Protestant missions

Women have not only provided the major support for mission in the modern era but also early recognized the need to found their own societies and send their own missionaries. In much of the world, because of local customs, women missionaries could perform services for other women and for children, especially in medicine and education, that men could not undertake. Their greatest impact was in the production of vast corps of able and educated women, especially in Asia, who played major roles in the professions and in church leadership.

Nondenominational faith missions viewed J. Hudson

Taylor's China Inland Mission (1865; after 1965 called the Overseas Missionary Fellowship) as the great prototype. Missions such as these often sought to work in areas unoccupied by other missionaries, guaranteed no salaries, and left financial support in God's hands; but most bodies made their financial needs known to a wide constituency. Their chief aim has been to proclaim the Gospel and eschew the provision of social services. These societies joined together in the Interdenominational Foreign Mission Association (IFMA; 1917). Since the 1960s they have cooperated with the Evangelical Foreign Missions Association (EFMA; 1945), the missionary arm of the National Association of Evangelicals (1943), and, at the international level, with the World Evangelical Fellowship (1952).

In the early 19th century in India, William Carey, Joshua Marshman, and William Ward—the Serampore trio—worked just north of Calcutta. Their fundamental approach included translating the Scriptures, establishing a college to educate an Indian ministry, printing Christian literature, promoting social reform, and recruiting missionaries for new areas as soon as translations into that area's language were ready.

Alexander Duff (1806–78) gave India the pattern for an entire educational system, including colleges. By the 1860s education for women had advanced and nurses' training had begun; the education of women physicians began at the turn of the century. The Vellore Medical College is a monument to the missionary physician Ida Scudder (1870–1959). The vast majority of Indian nurses also have been Christian.

In Indonesia, Dutch chaplains established churches in the 17th century. In the mid-19th century, the German Rhenish Missionary Society enabled the Batak Church of Sumatra to grow in size and commitment and to provide leadership for the nation. Other strong churches developed in various parts of predominantly Muslim Indonesia.

Following the Opium War treaties of 1842–44 and 1858–60, China was opened to Westerners. Although Roman Catholics remained from the efforts of the 16th-century Jesuit mission, the Chinese viewed Christianity as entering their homeland at gunpoint. The Boxer Rebellion of 1899–1900 brought death to thousands of Chinese Christians and several hundred missionaries. Yet what Protestant schools, colleges, and hospitals represented attracted Chinese youth to the Christian faith. With the fall of the Ch'ing, or Manchu, dynasty in 1911, Sun Yat-sen, a Christian favouring parliamentary government, became the provisional president. The Christian influence in China, particularly in education, was significant. In 1949, when the People's Republic of China was formed, Christians represented only 1 percent of the Chinese population, but they exercised an influence out of all proportion to their size.

The Chinese government expelled all missionaries in 1950–51, confiscated churches, and brought pressure on Christians. During the Cultural Revolution (1966–76) no churches or other religious bodies could operate. Christians continued to exist in China, but they suffered grievously. From 1976, as the government allowed some churches to open, Christians reemerged throughout the country. Roman Catholic and Protestant churches were filled, and in varied ways "silent" house-churches testified that the underground church had been dynamically growing. The state of the church in China, despite persecution, is considerably larger and stronger than it had been in 1949.

Koreans baptized as Roman Catholics in China returned in 1784 but remained underground when their faith was soon proscribed. A handful of American Presbyterians and Methodists entered Korea in 1884, and the faith they planted flourished through the 20th century, despite Korea's long wartime devastation. Evangelistic and self-supporting Korean churches were known throughout Asia for their effective promotion of Bible study. Helen Kim, a Korean graduate of Ewha College, built it into the world's largest women's university.

Christianity in Korea

Unlike other Asian countries, Korea did not experience Christianity's arrival with Western imperialism but rather saw that faith as reinforcing Korean nationalism against Japanese imperialism from 1910 to 1945. Korean evangelization enabled the church to grow in less than a century to about one-third of the population in South Korea. In the late 20th century, strong annual compounding growth continued—a situation unique among the Asian nations.

The vast Pacific Ocean, with tiny, scattered island kingdoms among the Polynesian, Micronesian, and Melanesian peoples, early attracted missionaries. Most of them were laypeople of deep Christian faith. It was the effort of the Christian islanders, however, that achieved virtually total evangelization of the Pacific.

In the Middle East, Protestants emphasized schools, colleges, and hospitals and witnessed to Muslims, though few Muslims became Christians. Humanitarian assistance by the Near East Relief, begun by American Protestant missions, helped those suffering during and after World War I, but this organization made its greatest efforts to aid the Armenian victims of genocide and forced deportation by the Turks. Later mission work was undertaken by the Near East Christian Council for Missionary Cooperation in Beirut (1924, 1929), which became the broadly ecumenical Near East Council of Churches in 1964.

Three major religions appear in sub-Saharan Africa: African traditional religion, Islām, and Christianity. Protestant missionaries were working in most of the West and Central African colonial nations in the 19th century, but in some parts of East Africa mission began only in the 20th century. After Ghana gained freedom in 1957, many former colonies were granted independence. Cataclysmic change appeared everywhere: in building new nations; rapid shifts from a rural to an urban population; coping with the massive problem, especially in cities, of some 2,500 languages; and developing literacy. Amid all this, Christianity grew with increasing rapidity. By 1980 more than half of the sub-Saharan African population was Christian. African independent, or indigenous nonwhite, churches proliferated, and several of the largest ones joined the World Council of Churches. These churches remain an important factor in African Christianity.

In the 19th century Evangelical churches were begun in Latin America by Protestant missionaries who were largely from the United States but also in some instances from Britain and Germany. Most of these churches have remained small. The exception was the explosion of Pentecostalism throughout the region, with heaviest concentration in Brazil, Chile, and Mexico. Evangelicals also have gained members in Central America.

Cooperation and unity

Protestants quickly discovered the need for cooperation and unity. As tiny minorities in lands of other religions, new Christians and missionaries together saw that denominational separatism hindered evangelization. Four streams led to the cooperation and unity reflected in the World Missionary Conference (WMC) held in Edinburgh in 1910.

First, missionary "field" conferences affirmed comity (separation of spheres of work), cooperation in Bible translation and missionary councils, and shared sponsorship in major enterprises such as hospitals and colleges. A second stream involved missionary conferences in England and the United States from 1854 to 1900. A third force flowed through the missionary concern of the international student Christian and missionary movements. The fourth stream arose in the West from continuing interdenominational conferences of mission leaders to face common concerns and forge common policies. Among others, these included the Continental European Missions Conference (1866) and the Foreign Missions Conference of North America (1893).

The Edinburgh conference was unique—a landmark and watershed for all that was to follow. Largely Western in membership, but with 17 Asian delegates, it created a Continuation Committee that in 1921 became the International Missionary Council (IMC). The IMC consisted of a worldwide network of Christian councils and the Western cooperative agencies. WMC continuation conferences in Asia (1912–13) reproduced the earlier conference in settings that incorporated national leaders of the Asian churches.

From the WMC and IMC also flowed the Faith and Order Movement (concerned with doctrine and ministry), Life and Work Movement (on the churches' moral respon-

sibility in society), and the World Council of Churches (WCC; 1948). The IMC's member bodies became national councils of churches. The IMC and the WCC, officially "in association with" each other, worked closely together. In 1961 the IMC became the Division of World Mission and Evangelism of the WCC.

Orthodox missions. Virtually the entire outreach of the Russian Orthodox mission extended to the peoples of the vast Russian Empire across Asia. Its outstanding missionaries included the linguist and translator Nicholas Ilminsky (d. 1891) and Ivan Veniaminov (1797–1879), who in 1823 went as its first missionary to the Aleutian Islands. Veniaminov eventually became Metropolitan Innocent of Moscow, and in 1870 he founded the Russian Orthodox Missionary Society. The Russian Orthodox Church opened a mission to Japan in 1854 and in 1941 turned over all church property to its members.

For some decades the church appointed missionaries to its highest posts. Tikhon (1865–1923), who in 1917 became the first patriarch in two centuries, and Sergius (Stragorodsky; 1867–1944), who followed him in that post, had both served missions abroad. Following the 1917 Revolution, Russian missions became impossible.

The African Orthodox Church, founded in Uganda in the 1920s by Reuben M. Spartas, spread to Kenya and Tanzania.

Fourth transition, from 1950. During the third transition, Christianity had spread worldwide from a base in Europe. The fourth transition brought the reality that more Christians lived in Asia, the Pacific Islands, Africa, and Latin America than in the old Christendom, part of a long-term, continuing shift in Christianity's numerical and vivifying centre. The growing churches brought new life and dynamism to the faith, along with new theologies and concerns.

Shift in Christianity's centre

The growth of the world Christian community kept pace with the 20th-century population explosion, and in the fastest-growing areas the growth rate in numbers of Christians was almost three times greater than the general population increase. The majority of the world's Christians lived in non-Western nations; a universal church had come into being.

In this transition two issues were especially prominent. First, the church found itself engaged with those of traditional or new religions and those for whom ideologies had become religions. In that setting the Roman Catholic Church and the Orthodox and Protestants in the World Council of Churches affirmed evangelization to be essential but also advanced dialogue for clarity, understanding, and basic engagement with other religions. This effort brought dissent and tension from many.

Second, "Third World theologies" often brought angry debate. The underlying questions concerned the identification of what was essentially Christian in Western Christianity and theology and whether Western church structures and theologies were universally normative. But the most basic question asked how Christians of all races could manifest the unity and obedience for which their Lord prayed.

Another force was the worldwide growth in the number of Pentecostals and charismatics. They formed new churches, appeared in traditional churches, and found outlet in many nonwhite indigenous bodies. Pentecostals and charismatics were most heavily concentrated in Latin America and Africa but also had grown in Asia and in the West. They forced theological reflection—perhaps best developed by Roman Catholics—on the doctrine of the Holy Spirit and on authority within the church.

Vatican II and mission

The second Vatican Council (1962–65) stood as the most important ecclesiological and missiological event for Roman Catholics since the 16th century. Theologically it set itself within the dynamics of the faith's fourth transition. The council's Decree on the Church's Missionary Activity (*Ad Gentes*) built theologically on the council's foundational document, the "Dogmatic Constitution on the Church" (*Lumen Gentium;* "Light of the Nations").

The "Dogmatic Constitution on the Church" rooted the church and mission in the triune Godhead, insisted upon evangelization but presented a larger understanding of God's grace for those outside the church, and urged missionaries to pursue dialogue.

In 1975 Pope Paul VI, responding to the ensuing debate, declared in *Evangelii Nuntiandi* ("Evangelization in the Modern World") that God can achieve salvation in anyone through God's own ways, but that witnessing to and preaching the Gospel is the regular pattern given to Christians. The Pope also presented a theology of liberation. In many respects his statement refined and replaced "The Church's Missionary Activity" (1965).

In 1968 the Latin American Episcopal Conference (CELAM) at Medellín, Colom., worked to apply the insights and intent of Vatican II to Latin America: first, to identify with the aspirations of the masses, and, second, to seek "re-evangelization" and "reconversion" in Latin America. At CELAM III (1979) in Puebla, Mex., the final document, "God's Saving Plan for Latin America," set forth a structure built upon *Evangelii Nuntiandi.*

Scripture translations. The translation of the Holy Scriptures has constituted a basic part of mission. During the Middle Ages few could read the Latin Bible. Within 80 years of the invention of printing in the West, however, Reformation leaders such as Luther and Calvin focused on the Word of God. Their cardinal principle remained that each should be able to read the Bible in his own tongue. The result was the development of education and literacy. The printing press greatly aided Protestantism, and widespread literacy again became the hallmark of a civilized society.

In the 20th century most of the world's people speak one of about 75 primary languages. A small minority speak one of 450 secondary languages, and more than 4,400 other languages are in use. Through Christian world mission, printed Scriptures have become available in the mother tongues of almost 99 percent of the world's people. That unprecedented accomplishment marks the greatest achievement in the history of written communications. Bibles are available in more than 300 languages, complete New Testaments in nearly 700 languages, and some portion of the Scriptures is available in 1,000 other languages. The translation effort, most of which has occurred during the past 200 years, has in many cases reduced a language to writing for the first time. The effort involved the production of grammars and dictionaries of these languages as well as scriptural translations, and an additional benefit has been the written preservation of the cultural heritage by native speakers of the language.

Bible societies, including the United Bible Societies (1946), have coordinated and aided the translation work of missionaries in this task for almost 200 years. Wycliffe Bible Translators (1936) concentrated its work among the language groups having the smallest numbers of speakers. From 1968 Roman Catholics and the United Bible Societies have coordinated their efforts and cooperated in translation and production wherever possible.

Christianity, unlike some of the other world religions, is a translating faith. In that area of God's mission the chief work in recent centuries has come from the Protestant community and has been offered as a gift to the church universal. This constitutes one of the great contributions of Christian mission to the world. (W.R.H.)

Ecumenism

The word ecumenism comes from a family of classical Greek words: *oikos,* meaning a "house," "family," "people," or "nation"; *oikoumenē,* "the whole inhabited world"; and *oikoumenikos,* "open to or participating in the whole world." Like many biblical words, these were invested with Christian meaning. The *oikoumenē* describes the place of God's reconciling mission (Matthew 24:14); the unity of the Roman Empire (Luke 2:1) and of the kingdoms of the earth (Luke 4:5); and the world destined to be redeemed by Christ (Hebrews 2:5). In the biblical community the vision of one church serving the purposes of God in the world came to reflect a central teaching of the early Christian faith, the essence of the church.

In later centuries the word ecumenical was used to denote those councils (*e.g.,* Nicaea, Chalcedon) of bishops whose

decisions represented the universal church, in contrast to other church councils that enjoyed only regional or limited reception. The honorary title of ecumenical patriarch was given to the Greek Orthodox patriarch of Constantinople because his see was located in the capital of the *oikoumenē* and his leadership was accepted as primus inter pares (first among equals) in the faith and mission of the whole church. The Apostles', the Nicene, and the Athanasian creeds are called ecumenical because they witness to the universal faith of all Christians. In the 19th and 20th centuries ecumenism denoted the movement of the renewal, unity, and mission of Christians and churches of different traditions "so that the world may believe."

Ecumenical participation

Ecumenism is a vision, a movement, a theology, and a mode of action. It represents the universality of the people of God, which affects the way Christians think about their faith, the church, and the world. Ecumenism, which is a long process, includes Bible study, dialogue, prayer, eucharistic worship, common witness, diaconal service, and ecclesial unity that draws Christians together, uniting their life and mission and bringing the Body of Christ and the human community closer to the fulfillment of God's purposes. To be involved in ecumenism means to participate in those ideas, activities, and institutions that express a spiritual reality of shared love in the church and the human community. It involves the work of officially organized ecumenical bodies, the confessing and witnessing of Christians in local places, and the spirituality and actions of those who live together in love and prophetic proclamation. Far more than a program or an organization, ecumenism is, according to the British ecumenist Oliver S. Tomkins, "something that happens to the soul of Christians."

Any unity worthy of this vision cannot be identified with political or spiritual coercion, strategies of dominance or superiority, calls for "a return to the mother church," or expectations of monolithic uniformity or a super-church. When serving the cause of faith, the weapons of faith are not those of force or intolerance; neither can divisions be overcome nor authentic unity manifested by syncretism, a least-common-denominator theology, or a casual friendliness. Ecumenism accepts the diversity of God's people, given in creation and redemption, and strives to bring these confessional, cultural, national, and racial differences into one fully committed fellowship.

Ultimately the purpose of ecumenism is to glorify the triune God and to help the one missionary church to witness effectively and faithfully among all peoples and nations. In the last half of the 20th century Christians have learned and confessed new dimensions of this vocation, especially in relation to what divides the churches. Progress has been made on historical theological issues that have alienated Christians through the centuries—baptism, the Eucharist, and ministry. But equally divisive among Christians are the divisions of the human family: racism, poverty, sexism, war, injustice, and differing ideologies. These issues are part of the agenda of ecumenism and bring a particular context, dynamic spirit, and urgency to the pursuit of Christian unity as well as of justice and peace. The church's unity becomes essential for the renewal and unity of the human family. Through its unity the church becomes a sign, the firstfruits of the promised unity and peace among God's peoples and the nations.

THE BIBLICAL PERSPECTIVE

The unity of the church and of all creation is a dominant motif in the Bible. This witness begins in the Old Testament, or Hebrew Scriptures, not the New Testament. God established a covenant with the Hebrew people and gathered the disparate tribes into one religious nation, Israel, taking steps to overcome the alienation between God and humans and to reconcile God's people. The tradition of ancient Judaism, therefore, was based on the reality of the one people of God. Their unity was an expression of their monotheistic faith, the oneness of God (Yahweh). As Genesis records, God created the world as one cosmos, an ordered unity determined by one single will in which all creatures are responsive to the purposes of the Creator. Yahweh chose Israel from all the nations of the world and entered into covenant with its people. Whenever men and women sinned and alienated themselves from God and from one another, God acted to bring about their reconciliation. Israel's mission was to preserve the faithfulness and unity of all God's people and to prepare them for the realization of the Kingdom of God.

The vision of unity is central to the Gospel of Jesus Christ and the teachings of his Apostles. Those who confess Jesus as Lord and Saviour are brought together in a new community: the church. All New Testament writers assume that to be "in Christ" is to belong to one fellowship (Greek: *koinōnia*). Jesus clearly gave the mandate when at the Last Supper he offered his high-priestly intercession, praying that the disciples and all those who believe in him "may all be one; even as thou, Father, art in me, and I in thee . . . so that the world may believe that thou hast sent me" (John 17:21). This unity was evidenced in the miracle of Pentecost (Acts 2) and other actions that constituted the primitive church—*e.g.*, the epoch-making Council of Jerusalem (Acts 15), which negotiated conflicts between Jewish and Gentile Christians.

Christ's mandate for unity

The early church nevertheless had many tensions and conflicts that called for ecumenical proclamations and pleas from the writers and Apostles of the New Testament. Tensions arose between Jewish Christian churches and Gentile Christian churches, between Paul and the enthusiasts, between John and early Catholicism. Peter and Paul disagreed strongly over whether Gentiles had to fulfill Jewish requirements in order to be welcome at the Lord's Supper (Eucharist). That theological aberrations challenged the young church is shown in the New Testament: Colossians refutes Gnosticism; the Johannine Epistles warn against Docetism; 2 Peter and Revelation attack false prophets.

None of this diversity created schism nor allowed a break in fellowship. There were no denominations or divided communities, as were to develop later in the church's history. Division among Christians is a denial of Christ, an unthinkable distortion of the reality of the church. Amid their diversity and conflicts the early Christians remained of "one accord," visibly sharing the one Eucharist, accepting the ministries of the whole church, reaching out beyond their local situation in faith and witness with a sense of the universal community that held all Christians together. As Paul taught the Ephesians, God's ultimate will and plan is "to unite all things in him [Christ], things in heaven and things on earth" (chapter 1, verse 10).

THE HISTORY OF ECUMENISM

While unity is given in Christ, church history chronicles two diametric forces in the church's life. One is the tendency toward sectarianism and division; the other is the conviction toward catholicity and unity. Ecumenism represents the struggle between them. Some of the schisms were theological conflicts foreshadowed in the apostolic church; others were internal quarrels related to liturgical differences, power politics between different patriarchates or church centres, problems of discipline and piety, or social and cultural conflicts. Nevertheless, according to the American historian John T. McNeill, "the history of the Christian Church from the first century to the 20th might be written in terms of its struggle to realize ecumenical unity."

Early controversies. A long and continuing trail of broken relations among Christians began in the 2nd century. Early in the 2nd century the Gnostics presented a serious doctrinal error and broke fellowship. Quartodecimanism, a dispute over the date of Easter, pitted Christians from Asia Minor against those from Rome. Montanism—which taught a radical enthusiasm, the imminent Second Coming of Christ, and a severe perfection, including abstinence from marriage—split the church. The Novatians broke fellowship with those Christians who, under pressure, offered sacrifices to pagan gods during the persecutions of the Roman emperor Decius in AD 250. In the early 4th century the Donatists, Christians in North Africa who prided themselves as the church of the martyrs, refused to share communion with those who had lapsed (*i.e.*, who had denied the faith under threat of death). The church

in Rome received the lapsed back into fellowship after services of repentance. This schism—like many since—reflected regional, national, cultural, and economic differences between the poor, rural North African Christians and the sophisticated, urban Romans.

In each century leaders and churches sought to reconcile these divisions and to manifest the visible unity of Christ's church. But in the 5th century a severe break in the unity of the church took place. The public issues were doctrinal consensus and heresy, yet in the midst of doctrinal controversy alienation was prompted by political, cultural, philosophical, and linguistic differences. Tensions increased as the church began to define—amid critical distortions by some—the relationship between God the Father and God the Son and later the relation between the divine and human elements in the nature and person of Jesus Christ. The first four ecumenical councils—at Nicaea (AD 325), Constantinople (381), Ephesus (431), and Chalcedon (451)—defined the consensus to be taught and believed, articulating this faith in the Nicene Creed and the Chalcedonian Definition, which stated that Jesus is the only begotten Son of God, true man, and true God, one person in "two natures without confusion, without change, without division, without separation." Two groups deviated doctrinally from the consensus developed in the councils. The Nestorians taught that there are two distinct persons in the incarnate Christ and two natures conjoined as one; Monophysites taught that there is one single nature, primarily divine. Several churches refused to accept the doctrinal and disciplinary decisions of Ephesus and Chalcedon and felt that they had no alternative but schism. These churches, called pre-Chalcedonian or Oriental Orthodox, became great missionary churches and spread to Armenia, Egypt, Ethiopia, Syria, Persia, and the Malabar coast of India in isolation from other churches.

Disputes regarding the nature of Christ

The schism of 1054. The greatest schism in church history occurred between the church of Constantinople and the church of Rome. While 1054 is the symbolic date of the separation, the agonizing division was six centuries in the making. The friction was ignited by several issues. The Eastern Church sharply disagreed when the Western Church introduced into the Nicene Creed the doctrine that the Holy Spirit proceeds not from the Father alone—as earlier Church Fathers taught—but from the Father and the Son (Latin: *filioque*). When the Roman Empire was divided into two zones, Latin-speaking Rome began to claim superiority over Greek-speaking Constantinople; disputes arose over church boundaries and control (for example, in Illyricum and Bulgaria). Rivalry developed in Slavic regions between Latin missionaries from the West and Byzantine missionaries from the East, who considered this territory to be Orthodox. Lesser matters related to worship and church discipline—for example, married clergy (Orthodox) versus celibacy (Roman Catholic) and rules of fasting—strained ecclesial relations. The tensions became a schism in 1054, when the uncompromising patriarch of Constantinople, Michael Cerularius, and the envoys of the uncompromising Pope Leo IX excommunicated each other. No act of separation was at this time considered final by either side. Total alienation came a half century later, as a result of the Crusades, when nominally Roman Catholic Christian soldiers made military campaigns to save Jerusalem and the Holy Land from the Muslims. In 1204 the Fourth Crusade was diverted to attack and capture Constantinople brutally. Thousands of Orthodox Christians were murdered; churches and icons were desecrated. As a consequence undying hostility developed between East and West.

Even so, certain leaders and theologians on both sides tried to heal the breach and reunite East and West. In 1274 the second Council of Lyon sought reunion. Agreements among the negotiators were achieved, including Orthodox acceptance of papal primacy and the acceptance of the Nicene Creed with the *filioque* clause. But the agreements were only a rushed action conditioned by political intrigue. As a result, reunion on these terms was fiercely rejected by the clergy and laity in Constantinople and other Orthodox provinces. A second attempt at reunion came at a council that met in Italy at Ferrara in 1438 and Florence in 1439. A formula of union was approved by both delegations, but later it was rejected by rank-and-file Orthodox Christians.

The Reformation. The 16th century experienced the next dramatic church division in the Reformation in the West. Like other schisms this one does not yield to simple analysis or exegesis. The Reformation was a mixture of theology, ecclesiology, politics, and nationalism, all of which led to breaks in fellowship and created institutional alienation between Christians in Germany, France, Switzerland, Scotland, England, and elsewhere. In one sense it was a separation, especially a reaction against the rigid juridical structures of medieval Roman Catholicism and its claim to universal truth and jurisdiction. In another sense, however, the Reformation was an evangelical and ecumenical renewal of the church as the Body of Christ, an attempt to return to the apostolic and patristic sources in order, according to Calvin, "to recover the face of the ancient Catholic Church." All the continental Reformers sought to preserve and reclaim the unity of the church.

Once the separation between the Roman Catholic Church and the emerging Protestant churches was conclusive, irenic persons on both sides tried to restore unity. Roman Catholics such as Georg Witzel and George Cassander developed proposals for unity, which all parties rejected. Martin Bucer, celebrated promoter of church unity among the 16th-century leaders, brought Luther and his colleague Philipp Melanchthon into dialogue with the Swiss Reformer Zwingli at Marburg, Ger., in 1529. In 1541 Calvin (who never ceased to view the church in its catholicity), Bucer, and Melanchthon met with Cardinal Gasparo Contarini and other Roman Catholics at Ratisbon (now Regensburg, Ger.) to reconcile their differences on justification by faith, the Lord's Supper, and the papacy. Another attempt was made in 1559, when Melanchthon and Patriarch Joasaph II of Constantinople corresponded, with the intention of using the Augsburg Confession as the basis of dialogue between Lutherans and Orthodox. On the eve of the French religious wars (1561) Roman Catholics and Protestants conferred without success in the Colloquy of Poissy. It would seem that the ecumenical projects of theologians and princes in 16th-century Europe failed unequivocally, but they kept alive the vision and the hope.

Ecumenical efforts of Bucer and Melanchthon

Ecumenism in the 17th and 18th centuries. During the 17th and 18th centuries storms of contention and division continued to plague the churches throughout Europe. The Church of England, severed from the Roman Catholic Church in the 16th century by Henry VIII and his English theologians, experienced its first internal split when it was unable or unwilling to embrace John Wesley and the Methodist Church's insights for spiritual renewal.

During these two centuries there was an eclipse of official, church-to-church attempts at unity. Instead, ecumenical witness was made by individuals who courageously spoke and acted against all odds to propose Christian unity. John Amos Comenius, a Czech Brethren educator and advocate of union, produced a plan of union for Protestants based upon the adoption of a scriptural basis for all doctrine and polity and the integration of all human culture.

Ecumenical witness by individuals

In England, John Dury, a Scots Presbyterian and (later) an Anglican minister, "a peacemaker without partiality," traveled more extensively than any other ecumenist before the 19th century, negotiating for church unity in his own country and in Sweden, Holland, France, Switzerland, and Germany. Richard Baxter, a Presbyterian Puritan, developed proposals for union, including his Worcestershire Association, a local ecumenical venture uniting Presbyterians, Congregationalists, and Anglicans.

Efforts were undertaken in Germany as well. The German Lutheran George Calixtus called for a united church between Lutherans and Reformed based on the "simplified dogmas," such as the Apostles' Creed and the agreements of the church in the first five centuries. Count Nicholas von Zinzendorf applied his Moravian piety to the practical ways that unity might come to Christians of all persuasions. The philosopher Gottfried Wilhelm Leibniz worked tirelessly for union between Protestants and Roman Catholics, writing an apologia interpreting Roman Catholic doctrines for Protestants.

Orthodox Christians also participated in the search for union. Metropolitan Philaret of Moscow and the Russian Orthodox theologian Aleksey S. Khomyakov expressed enthusiasm for ecumenism. Cyrillus Lukaris, Orthodox patriarch of Alexandria and later of Constantinople, took initiatives to reconcile a divided Christendom. People throughout Europe held tenaciously to the dream of ecumenism, although no attempt at union reached fruition.

19th-century efforts. In the 19th century a worldwide movement of evangelical fervour and renewal, noted for its emphasis on personal conversion and missionary expansion, stirred new impulses for Christian unity. The rise of missionary societies and volunteer movements in Germany, Great Britain, The Netherlands, and the United States expressed a zeal that fed the need for church unity. As missionaries in different countries began to experience the harmful results of Christian divisions, cooperation among Protestant missionaries began to take place in India, Japan, China, Africa, Latin America, and the United States.

Growth of ecumenical societies

In 1804 the British and Foreign Bible Society came into existence to bring Protestants and Anglicans together in the translation and distribution of the Scriptures. This was followed, 40 years later, by the founding of two important Christian organizations in England: the Young Men's Christian Association (1844) and the Young Women's Christian Association (1855). Their international bodies, the World Alliance of YMCAs and the World YWCA, were established in 1855 and 1894, respectively. The Evangelical Alliance, possibly the most significant agent of Christian unity in the 19th century, held a unique place among the volunteer associations of individuals for common service and mission. Founded in London in 1846 (with an American section in 1867), the alliance sought to draw individual Christians into fellowship and cooperation in prayer for unity, Christian education, the struggle for human rights, and mission.

Also pivotal in the 19th century were advocates for the visible unity of the church. In the United States, where the most articulate 19th-century unity movements were heard, the witness to the unity and union was led by three traditions. Among Lutherans, Samuel Simon Schmucker and Philip Schaff pleaded for "catholic union on apostolic principles." Among Episcopalians, the visionaries for unity included Thomas Hubbard Vail, William Augustus Muhlenberg, and William Reed Huntington, who proposed the historic "Quadrilateral" of the Scriptures, the creeds, the sacraments of baptism and the Lord's Supper, and episcopacy as the keystone of unity. Among the Disciples of Christ the biblical vision of unity was dramatically offered by Thomas Campbell and his son, Alexander, and Barton Warren Stone—all of whom taught that "the Church of Christ on earth is essentially, intentionally and constitutionally one." Ecumenism was enflamed in the hearts of 19th-century Christians and in the next century began to shape the churches as never before.

Ecumenism in the 20th century. The 20th century experienced a flowering of ecumenism. Four different strands—the international Christian movement, cooperation in world mission, Life and Work, and Faith and Order—developed in the early decades and, though distinctive in their emphases, later converged to form one ecumenical movement.

The modern ecumenical era began with a worldwide movement of Christian students, who formed national movements in Great Britain, the United States, Germany, Scandinavia, and Asia. In 1895 the World Student Christian Federation, the vision of American Methodist John R. Mott, was established "to lead students to accept the Christian faith" and to pioneer in Christian unity. The

The 1910 Edinburgh conference

World Missionary Conference at Edinburgh (1910) inaugurated another aspect of ecumenism by dramatizing the necessity of unity and international cooperation in fulfilling the world mission of the church. In 1921 the International Missionary Council (IMC) emerged, bringing together missionary agencies of the West and of the new Christian councils in Asia, Africa, and Latin America for joint consultation, planning, and theological reflection. The Life and Work movement was pledged to practical Christianity and common action by focusing the Christian conscience on international relations and social, industrial, and economic problems. Nathan Söderblom, Lutheran archbishop of Uppsala, inspired world conferences on Life and Work at Stockholm (1925) and Oxford (1937). The Faith and Order movement, which originated in the United States, confronted the doctrinal divisions and sought to overcome them. Charles H. Brent, an Episcopal missionary bishop in the Philippines, was chiefly responsible for this movement, although Peter Ainslie, of the Disciples of Christ, shared the same vision and gave significant leadership. World conferences on Faith and Order at Lausanne (1925), Edinburgh (1937), Lund (1952), and Montreal (1963) guided the process of theological consensus-building between Protestants, Orthodox, and Roman Catholics, which led to approval of the historic convergence text on *Baptism, Eucharist, and Ministry* (1982).

The World Council of Churches

The World Council of Churches (WCC) is a privileged instrument of the ecumenical movement. Constituted at Amsterdam in 1948, the conciliar body includes more than 300 churches—Protestant, Anglican, and Orthodox—which "confess the Lord Jesus Christ as God and Saviour according to the Scriptures and therefore seek to fulfill together their common calling to the glory of the one God, Father, Son, and Holy Spirit." Its general secretaries have been among the architects of 20th-century ecumenism: W.A. Visser 't Hooft, (The Netherlands), Eugene Carson Blake (United States), Philip Potter (Dominica), and Emilio Castro (Uruguay). The witness and programs of the WCC include faith and order, mission and evangelism, refugee and relief work, interfaith dialogue, justice and peace, theological education, and solidarity with women and the poor. What distinguishes the WCC constituency is the forceful involvement of Orthodox churches and churches from the Third World. Through their active presence the WCC, and the wider ecumenical movement, has become a genuinely international community.

Roman Catholic ecumenism received definitions and momentum at the second Vatican Council (1962–64), under the ministries of popes John XXIII and Paul VI, and through the ecumenical diplomacy of Cardinal Augustin Bea, the first president of the Secretariat for Promoting Christian Unity. The church gave the ecumenical movement new hope and language in the "Decree on Ecumenism" (1964), one of the classic ecumenical teaching documents. Another result of Vatican II was the establishment of a wide variety of international theological dialogues, commonly known as bilateral conversations. These include Roman Catholic bilaterals with Lutherans (1965), Orthodox (1967), Anglicans (1967), Methodists (1967), Reformed (1970), and the Disciples of Christ (1977). Topics identified for reconciling discussions include baptism, the Eucharist, episcopacy and papacy, authority in the church, and mixed marriage.

Critical to 20th-century ecumenism is the birth of united churches, which have reconciled formerly divided churches in a given place. In Asia and Africa the first united churches were organized in China (1927), Thailand (1934), Japan (1941), and the Philippines (1944). The most heralded examples of this ecumenism are the United Church of Canada (1925), the Church of South India (1947), and the Church of North India (1970). Statistics of other united churches are revealing. Between 1948 and 1965, 23 churches were formed. In the period from 1965 to 1970 unions involving two or more churches occurred in the West Indies in Jamaica and Grand Cayman, Ecuador, Zambia, Zaire, Pakistan, Madagascar, Papua New Guinea, the Solomon Islands, and Belgium. Strategic union conversations were undertaken in the United States by the nine-church Consultation on Church Union (1960) and by such uniting churches as the United Church of Christ (1957), the Presbyterian Church, U.S.A. (1983), and the Evangelical Lutheran Church in America (1988).

Spiritual disciplines play a key role in ecumenism, a movement steeped in prayer for unity. During the Week of Prayer for Christian Unity, celebrated every year (January 18–25), Christians from many traditions engage in prayer, Bible study, worship, and fellowship in anticipation of the unity Christ wills. (P.A.C.)

The Christian church and non-Christian religions

A spiritual encounter and discussion of Christianity with other world religions has begun only during the 20th century as a consequence of change in the general religious, political, and economic situation of the world. The global spread of Christianity through the activity of the European and American churches in the 18th and 19th centuries led to Christianity's immediate encounter with all other existing religions. Until the beginning of the 19th century there were still places on Earth where non-Christian religions never came into contact with Christianity. Since then, Christianity has entered into a direct contact with all living non-Christian religions in the world. The close connection between Christian world missions and political, economic, technical, and cultural expansion has, at the same time, been loosened.

Recent Christianity's contacts with non-Christian religions

After World War II, the former mission churches were transformed into independent churches in the newly autonomous Asian and African states. The concern for a responsible cooperation of the members of Christian minority churches and its non-Christian fellow citizens became the more urgent with a renaissance of the Asian higher religions in numerous Asian states. Since World War II Hinduism, Buddhism, and Islām have been trying to regain their former position of leadership in intellectual and spiritual life, mainly in the educational systems of their countries in the Asian states and—in the case of Islām—in some African states.

All Asian higher religions have also turned to activities in world missions in Christian countries in Europe, the Americas, and Australia. Hinduism, for example, has founded numerous Vedānta centres in North America and Europe within the framework of the Ramakrishna and Vivekananda missions. South Asian Theravāda (Way of the Elders) Buddhism and the Mahāyāna (Greater Vehicle) Buddhism of Japan (mainly Zen Buddhism, an intuitive-meditative sect) have begun world missionary activities under the influence of a Buddhist renaissance. This influence has penetrated Europe and North America not so much in the form of a directly organized mission as in the form of a spontaneously received flow of religious ideas and methods of meditation through literature, philosophy, psychology, and psychotherapy. As a result, Christianity in the latter part of the 20th century found itself forced to enter into a factual discussion with non-Christian religions, particularly because the constitutional privileges once enjoyed by certain religions had been rescinded in most states.

Modern history of religions, on the other hand, has caused a general transformation of religious consciousness in the West since the middle of the 19th century. Until the beginning of the 20th century, the knowledge of non-Christian higher religions was still the privilege of a few specialists. In the meantime, in a second wave of enlightenment, a wide range of people have studied the results of research in the form of translations of source materials from the non-Christian religions. The spreading of the religious art of Tibet, India, and the Far East through touring exhibitions and the possibility of a direct participation in non-Christian religious ceremonies through radio and television has created a new attitude toward the other religions in the broad public of Europe and North America. The knowledge of the plurality of the world religions characterizes the religious consciousness of the 20th century in a way that was unknown in former centuries. In recognition of this fact, numerous Christian institutions for the study of non-Christian religions have been founded: *e.g.*, in Bangalore, India; in Rangoon, Burma; in Bangkok, Thailand; in Kyōto, Japan; and in Hong Kong. There are also a number of more specialized centres in several countries.

The increase of knowledge of non-Western religions in the West

The readiness of encounter or even cooperation of Christianity with non-Christian religions is a phenomenon of modern times, with few precedents in the history of the struggle of Christianity and the non-Christian religions. Until the 18th century, Christianity showed little inclination to engage in a serious study of non-Christian religions. Four hundred years after the beginning of the struggle with the Muslims in Spain, almost half a century after the proclamation of the First Crusade against Islām, Peter the Venerable, abbot of Cluny, issued the first translation of the Qur'ān (the Islāmic scriptures) in 1141 in Toledo; but he was not understood by his contemporaries. Bernard of Clairvaux, the propagator of the Second Crusade, even refused to read it. Four hundred years later, in 1542/43, Theodor Bibliander, a theologian and successor of the Swiss Reformer Zwingli, edited the translation of the Qur'ān by Peter the Venerable again. He was subsequently arrested, and he and his publisher could be freed only through intervention by Luther.

Knowledge of Hinduism was sometimes deliberately delayed by the missionaries. August Hermann Francke, the supporter of the Lutheran Tranquebar mission in India, prevented the publication of the work of the missionary Bartholomäus Ziegenbalg about the religion of the non-Christian Malabarese of India. The name Buddha is mentioned for the first time in Christian literature—and there only once—by Clement of Alexandria about AD 200; and it vanished after that from Christian literature for a full 1,300 years. Pāli, the language of the Buddhist canon, remained unknown in the West until the beginning of the 19th century, when modern Buddhology was founded.

The reasons for such reticence toward contact with foreign religions were twofold: (1) The ancient church was significantly influenced by the Jewish attitude toward the pagan religions of its environment. Like Judaism, it viewed the pagan gods as "nothings" next to the true God, the Creator of the world and, in the case of the Christians, the Father of Jesus Christ; they were offsprings of human error that were considered to be identical with the wooden, stone, or bronze images that were made by humans. (2) Besides this, there was the tendency to degrade the pagan gods as demons, evil demonic forces engaged in mortal combat with the true God. The conclusion of the history of salvation, according to the Christian understanding, was to be a final struggle between Christ and his church on the one side and the forces, powers, and thrones of the Antichrist on the other, culminating finally with the victory of Christ.

Reasons for the reticence of contacts with non-Christian religions

CONFLICTING CHRISTIAN ATTITUDES

The history of religion, however, continued even after Christ. During the 3rd and 4th centuries a new non-Christian world religion appeared in the form of Manichaeism, which countered the Christian Church with new holy books, a new institution, and a new universal claim of validity. The Christian Church never acknowledged Manichaeism as a new religion but considered it a Christian heresy and opposed it as such.

When Islām was founded in the 7th century as a new higher religion, it considered revelation as received by the Prophet Muḥammad to be superior to the former levels of Old and New Testament revelation. Christianity also fought Islām as a Christian heresy. This new threat was seen as the fulfillment of the eschatological prophecies of the Apocalypse concerning the coming of the "false prophet" (Revelation to John). The apocalyptic interpretation of Islām as the religion of the "false prophet" also coined the archetypal struggle of the Christian Church of the Middle Ages against foreign religions, namely, the crusade. The idea of the Crusades deeply influenced the self-consciousness of Western Christianity even in later centuries.

The dialogue of the 15th-century German theologian Nicholas of Cusa on the peace of faith (1453) is the first Christian document that calls for the establishment of an eternal peace among world religions. In spite of this, the idea of the crusade remained the model for the fulfillment of the new missionary task that arose within the Roman Catholic Church with the discovery and exploration of the American continents by Spain and Portugal. Only the penetration of the Islāmic wall that had separated Europe spiritually and economically from the empires of the Asian higher religions and only the encounter with these higher religions in countries such as China and Japan—which could not be subjugated to the rule of Roman Catholic

The peace of faith

kings by the sword—led to a gradual overcoming of the idea of the crusade. In China and Japan the missionaries saw themselves forced into an argument with the indigenous higher religions that could be carried on only with intellectual weapons. The old Logos theory prevailed in a new form that was founded on natural law, particularly among the Jesuit theologians who worked at the Chinese emperor's court in Peking.

The philosophy of the Enlightenment in the 18th century spread the acknowledgment of a plurality of higher religions among the educated in Europe, partly—as in the case of the German philosopher Gottfried Wilhelm Leibniz—in immediate connection with the theories of natural law of the Jesuit missionaries in China. This insight pointed to the striking convergence of non-Christian higher religions with Christianity and in that way prepared the development of the comparative study of religion. Only in the philosophy of the Enlightenment was the demand of tolerance, which thus far in Christian Europe had been applied solely as a postulate of behaviour toward the followers of another Christian denomination, extended to include the followers of different religions.

Pietistic missionary activities

The missions that were carried out in the late 18th and the 19th centuries by pietistically or fundamentally oriented churches ignored this knowledge or consciously fought against it. Simple lay Christianity of revivalist congregations demanded that a missionary denounce all pagan "idolatry." The spiritual and intellectual argument with non-Christian higher religions simply did not exist for this simplified fundamental theology, and in this view a real encounter of Christianity with non-Christian higher religions did not, on the whole, occur in the 18th and 19th centuries. (E.W.B./J.Hi.)

MODERN VIEWS

The 20th century has seen an explosion of publicly available information concerning the wider religious life of humanity, as a result of which the older Western assumption of the manifest superiority of Christianity has lost plausibility in many minds. Early 20th-century thinkers such as Rudolf Otto, who saw religion throughout the world as a response to the Holy, and Ernst Troeltsch, who showed that socioculturally Christianity is one of a number of comparable traditions, opened up new ways of regarding the other major religions.

Exclusivism, inclusivism, and pluralism

Given that the central concern of both Christianity and the other great world faiths is salvation, Christians today adopt one of three main points of view. One is exclusivism, which holds that there is salvation only for Christians. This theology underlay much of the history outlined above, expressed both in the Roman Catholic dogma *extra ecclesiam nulla salus* ("outside the church no salvation") and in the assumption of the 18th- and 19th-century Protestant missionary movements that outside the proclaimed Gospel there is no salvation. The exclusivist outlook was eroded within advanced Roman Catholic thinking in the decades leading up to the second Vatican Council (1962–65) and was finally abandoned in the council's pronouncements. Within Protestant Christianity there is no comparable central authority, but most Protestant theologians, except within the extreme Fundamentalist constituencies, have also moved away from the exclusivist position.

The move, among both Roman Catholics and Protestants, has been toward inclusivism, the view that, although salvation is by definition Christian salvation, brought about by the atoning work of Christ, it is nevertheless in principle available to all human beings, whether Christian or not. The Roman Catholic theologian Karl Rahner expressed the inclusivist view by saying that good and devout people of other faiths may, even without knowing it, be regarded as "anonymous Christians." Others have expressed in different ways the thought that non-Christians also are included within the universal scope of Christ's salvific work and their religions fulfilled in Christianity.

The third position, to which a number of individual theologians have moved in recent years, is pluralism. According to this view, the great world faiths, including Christianity, are valid spheres of a salvation that takes characteristically different forms within each—though consisting in each case in the transformation of human existence from self-centredness to a new orientation toward the Divine Reality. The other religions are thus not secondary contexts of Christian redemption but independently authentic paths of salvation. The pluralist position is controversial in Christian theology because it affects the ways in which the doctrines of the person of Christ, atonement, and the Trinity are formulated.

Christians engage in dialogue with the other major religions through the World Council of Churches' subunit on Dialogue with People of Living Faiths and Ideologies and the Vatican's Secretariat for Non-Christians, as well as a variety of extra-ecclesiastical organizations, such as the World Congress of Faiths. A multitude of interreligious encounters takes place throughout the world, many initiated by Christian and others by non-Christian individuals and groups. (J.Hi.)

MINEAR, *Christian Hope and the Second Coming* (1954); RUDOLF BULTMANN, *History and Eschatology* (U.S. title, *The Presence of Eternity,* 1957, reissued 1975); OSCAR CULLMANN, *Christ and Time: The Primitive Christian Conception of Time and History,* rev. ed. (1962, reprinted 1964; originally published in German, 1946); JÜRGEN MOLTMANN, *Theology of Hope: On the Ground and the Implications of a Christian Eschatology* (1967, reprinted 1975; originally published in German, 1964), and *Hope and Planning,* trans. from German (1971); WILLIAM STRAWSON, *Jesus and the Future Life,* new and rev. ed. (1970); and GEOFFREY WAINWRIGHT, *Eucharist and Eschatology,* 2nd ed. (1978, reprinted 1981).

Church year: LOUIS DUCHESNE, *Christian Worship: Its Origin and Evolution,* 5th ed. (1919, reprinted 1956; originally published in French, 4th rev. and enl. ed., 1908), ch. 8, is fundamental but should be supplemented by later handbooks, such as J.A. JUNGMANN, *Public Worship* (1957, reissued 1966; originally published in German, 1955), ch. 9; and JOHN H. MILLER, *Fundamentals of the Liturgy* (1960, reprinted 1964), ch. 8. Good summary accounts are those of NOËLE M. DENIS-BOULET, *The Christian Calendar* (1960; originally published in French, 1959); A. ALAN MCARTHUR, *The Evolution of the Christian Year* (1953); and ADOLF ADAM, *The Liturgical Year: Its History & Its Meaning After the Reform of the Liturgy* (1981), basic for present Roman Catholic use. THOMAS J. TALLEY, *The Origins of the Liturgical Year* (1986), is a fresh reading of the early evidence. More popular treatments, valuable for their detail of popular observance, are the works of FRANCIS X. WEISER, *The Christmas Book* (1952, reissued 1954), *The Easter Book* (1954), *The Holyday Book* (1956), and *Handbook of Christian Feasts and Customs: The Year of the Lord in Liturgy and Folklore* (1958). See also SUE SAMUELSON, *Christmas: An Annotated Bibliography* (1982). Insights into primitive and non-Christian backgrounds of the church year are contained in MIRCEA ELIADE, *The Myth of the Eternal Return* (1954, reprinted 1974; originally published in French, 1949); and E.O. JAMES, *Seasonal Feasts and Festivals* (1961, reprinted 1963). For Jewish background, see ROLAND DE VAUX, *Ancient Israel: Its Life and Institutions* (1961, reissued 1973; originally published in

French, 2 vol., 1958–60), pt. 4, ch. 15–18. A standard monograph on the origin of the seven-day week is F.H. COLSON, *The Week* (1926, reprinted 1974). EVIATAR ZERUBAVEL, *The Seven Day Circle: The History and Meaning of the Week* (1985), is a comprehensive historical, cultural, and sociological study. More exhaustive and detailed is WILLY RORDORF, *Sunday: The History of the Day of Rest and Worship in the Earliest Centuries of the Christian Church* (1968; originally published in German, 1962). For historical discussions of Holy Week and Easter, see MASSEY H. SHEPHERD, JR., *The Paschal Liturgy and the Apocalypse* (1960); and JOHN WALTON TYRER, *Historical Survey of Holy Week: Its Services and Ceremonial* (1932). CLARENCE SEIDENSPINNER, *Great Protestant Festivals* (1952), defends nontraditional observances in modern Protestant churches.

Canon law: A short introduction is provided by LADISLAS M. ORSY, *From Vision to Legislation: From the Council to a Code of Laws* (1985). The most important modern works on the history of canon law are HANS E. FEINE, *Kirchliche Rechtsgeschichte: Die katholische Kirche,* 5th ed. (1972); WILLIBALD M. PLÖCHLE, *Geschichte des Kirchenrechts,* 2nd enl. ed., 5 vol. (1960–70); and GABRIEL LE BRAS (ed.), *Histoire du droit et des institutions de l'eglise en occident* (1955–), with 12 vol. published by 1987. The articles in R. NAZ (ed.), *Dictionnaire de droit canonique,* 7 vol. (1935–65), although in need of updating, can still provide much historical and doctrinal information. A respected analytical commentary on the 1917 code is A. VERMEERSCH and J. CREUSEN, *Epitome Iuris Canonici,* 7th ed. rev. by R.P. CREUSEN, 3 vol. (1949–56), in Latin. Commentaries on the 1983 code include JAMES A. CORIDEN, THOMAS J. GREEN, and DONALD E. HEINTSCHEL (eds.), *The Code of Canon Law: A Text and Commentary* (1985), intended mainly for practitioners; JOSEPH LISTL, HUBERT MÜLLER, and HERIBERT SCHMITZ (eds.), *Handbuch des katholischen Kirchenrechts* (1983), a doctrinally elaborate, thematically organized work; and KLAUS LÜDICKE (ed.), *Münsterischer Kommentar zum Codex Iuris Canonici* (1985–), kept up to date by frequent loose-leaf supplements concerning official pronouncements and current literature. Bibliographies are found in the series "Repertoire Bibliographique des Institutions Chrétiennes" (1969–), with text in French, English, German, Italian, and Spanish.

Patristic literature: The most important texts on the Church Fathers are BERTOLD ALTANER, *Patrology* (1960; originally published in German, 1938); F.L. CROSS, *The Early Christian Fathers* (1960); and JOHANNES QUASTEN, *Patrology,* 3 vol. (1950–60, reprinted 1983), continued by ANGELO DI BERARDINO (ed.), *Patrology: The Golden Age of Latin Patristic Literature from the Council of Nicea to the Council of Chalcedon* (1986; originally published in Italian, 1978). Other works include HANS VON CAMPENHAUSEN, *The Fathers of the Greek Church* (1959, reissued 1963; originally published in German, 1955), and *The Fathers of the Latin Church* (1964, reprinted 1969; originally published in German, 1960); FRANCES M. YOUNG, *From Nicaea to Chalcedon: A Guide to the Literature and Its Background* (1983), on the chief Greek Fathers from 325 to 451; and BONIFACE RAMSEY, *Beginning to Read the Fathers* (1985). See also the volumes in the series "Message of the Fathers of the Church" (1983–).

Christian philosophy: On the early period, CLAUDE TRESMONTANT, *The Origins of Christian Philosophy* (1962; originally published in French, 1962); A.H. ARMSTRONG and R.A. MARKUS, *Christian Faith and Greek Philosophy* (1960, reissued 1964); and ADAM FOX (ed. and trans.), *Plato and the Christians* (1957), cover the Hebraic and Greek sources of Christian thought. The classic works on the medieval period are ÉTIENNE GILSON, *The Spirit of Mediaeval Philosophy* (1936; originally published in French, 2 vol., 1932), *Reason and Revelation in the Middle Ages* (1938, reprinted 1966), and *History of Christian Philosophy in the Middle Ages* (1955, reissued 1980). See also PHILIPPE DELHAYE, *Medieval Christian Philosophy* (1960; originally published in French, 1959). J.V. LANGMEAD CASSERLEY, *The Christian in Philosophy* (1949, reissued 1955); and GEORGE F. THOMAS, *Religious Philosophies of the West* (1965), and *Philosophy and Religious Belief* (1970), provide broad surveys up to the contemporary period. For existentialism, see DAVID E. ROBERTS, *Existentialism and Religious Belief* (1957). Much of the contemporary discussion takes place in articles, such as those collected in BASIL MITCHELL (ed.), *The Philosophy of Religion* (1971, reprinted 1978), all of whose contributors are Christian philosophers grappling with current issues. Also useful are STUART C. BROWN (ed.), *Reason and Religion* (1977); RICHARD SWINBURNE, *The Existence of God* (1979); HANS KÜNG, *Does God Exist?: An Answer for Today* (1980; originally published in German, 1978); ALVIN PLANTINGA and NICHOLAS WOLTERSTORFF (eds.), *Faith and Rationality: Reason and Belief in God* (1983); and LEROY S. ROUNER (ed.), *Religious Pluralism* (1984). *Faith and Philosophy: Journal of the Society of Christian Philosophers* (quarterly) is another forum of contemporary discussion.

Mysticism: General descriptive approaches include EVELYN UNDERHILL, *Mysticism: A Study in the Nature and Development of Man's Spiritual Consciousness* (1911, reissued 1977); R.C. ZAEHNER, *Mysticism, Sacred and Profane: An Inquiry Into Some Varieties of Praeter-Natural Experience* (1957, reissued 1980); SIDNEY SPENCER, *Mysticism in World Religion* (1963, reissued 1971); and ANDREW LOUTH, *The Origins of the Christian Mystical Tradition from Plato to Denys* (1981, reprinted 1983). A good anthology is that of ELMER O'BRIEN, *Varieties of Mystic Experience* (1964). Many of the texts of the great Christian mystics have been published in new translations in "The Classics of Western Spirituality" series (1978–). Helpful for the serious student are the classic works of WILLIAM JAMES, *The Varieties of Religious Experience: A Study in Human Nature* (1902, reissued 1985); FRIEDRICH VON HÜGEL, *The Mystical Element of Religion: As Studied in Saint Catherine of Genoa and Her Friends,* 2 vol. (1908, reprinted 1961); CUTHBERT BUTLER, *Western Mysticism: The Teaching of SS Augustine, Gregory, and Bernard on Contemplation and the Contemplative Life* (1922, reprinted 1975); JOSEPH MARÉCHAL, *Studies in the Psychology of the Mystics* (1927; originally published in French, 2 vol., 1924–37); ALBERT SCHWEITZER, *The Mysticism of Paul the Apostle* (1931, reissued 1968; originally published in German, 1930); HENRI BERGSON, *The Two Sources of Morality and Religion* (1935; originally published in French, 1932); RUDOLF OTTO, *Mysticism East and West: A Comparative Analysis of the Nature of Mysticism* (1932, reissued 1987; originally published in German, 1926); JACQUES MARITAIN, *Distinguish to Unite: or, The Degrees of Knowledge* (1959; originally published in French, 4th ed., 1946). For recent issues, see STEVEN T. KATZ (ed.), *Mysticism and Philosophical Analysis* (1978); and PHILLIP C. ALMOND, *Mystical Experience and Religious Doctrine: An Investigation of the Study of Mysticism in World Religions* (1982). The most important recent theological contributions have been those of KARL RAHNER, *The Practice of Faith: A Handbook of Contemporary Spirituality* (1983, reprinted 1986; originally published in German, 1982); and HANS URS VON BALTHASAR, *The Glory of the Lord: A Theological Aesthetics,* trans. from German (1981–).

Christian myth and legend: On the nature of myth, see MIRCEA ELIADE, *Myth and Reality* (1963, reprinted 1975; originally published in French, 1963). WILLIAM G. DOTY, *Mythography: The Study of Myths and Rituals* (1986), analyzes a number of important approaches to the study of myth and, in addition, offers extensive bibliographies. Resistance to myth and legend in early Christianity is described in WALTER BAUER, *Orthodoxy and Heresy in Earliest Christianity* (1971, reprinted 1979; originally published in German, 1934). MIRCEA ELIADE, *A History of Religious Ideas,* 3 vol. (1978–85; originally published in French, 3 vol., 1976–83), discusses Christian myth and legend in several chapters.

On the androgyny of Christ, see WAYNE A. MEEKS, "The Image of the Androgyne: Some Uses of a Symbol in Earliest Christianity," *History of Religions,* 13(3):165–208 (Feb. 1974); and CAROLINE WALKER BYNUM, *Jesus as Mother: Studies in the Spirituality of the High Middle Ages* (1982, reprinted 1984). GEO WIDENGREN, *Mesopotamian Elements in Manichaeism (King and Saviour II): Studies in Manichaean, Mandaean, and Syrian-Gnostic Religion* (1946); and ROBERT MURRAY, *Symbols of Church and Kingdom: A Study in Early Syriac Tradition* (1975, reprinted 1977), discuss the origins of sacramental oils. HUGO RAHNER, *Greek Myths and Christian Mystery* (1963, reissued 1971; originally published in German, 1945), traces the theme of the Christian World Tree.

For apocryphal gospels, see MORTON SMITH, *The Secret Gospel: The Discovery and Interpretation of the Secret Gospel According to Mark* (1973, reissued 1982); JAMES M. ROBINSON (comp.), *The Nag Hammadi Library in English* (1977); JACQUES E. MÉNARD, *L'Évangile selon Philippe* (1964, reissued 1967), and *L'Évangile selon Thomas* (1975); and the series "Bibliothèque copte de Nag Hammadi: section textes" (1977–). See also CHARLES W. HEDRICK and ROBERT HODGSON, JR. (eds.), *Nag Hammadi, Gnosticism, & Early Christianity* (1986). For the *Protogospel of James,* the *Chronicle of Zugnin,* and the *Opus Imperfectum in Matthaeum,* see UGO MONNERET DE VILLARD, *Le leggende orientali sui magi evangelici* (1952). On Bogomil and Cathar apocrypha, see ÉMILE TURDEANU, "Apocryphes bogomiles et apocryphes pseudo-bogomiles," *Revue de l'Histoire des Religions* 138:22–52, 176–218 (1950); and EDINA BOZÓKY (ed. and trans.), *Le Livre secret des cathares, interrogatio Iohannis: apocryphe d'origine bogomile* (1980).

On the cult of saints, see H. DELEHAYE, *The Legends of the Saints: An Introduction to Hagiography* (1907, reprinted 1974; originally published in French, 1905); LAWRENCE S. CUNNINGHAM, *The Meaning of Saints* (1980); PETER BROWN, *The Cult of the Saints: Its Rise and Function in Latin Christianity* (1981); DONALD WEINSTEIN and RUDOLPH M. BELL, *Saints & Society: The Two Worlds of Western Christendom, 1000–1700* (1982,

reprinted 1986); and STEPHEN WILSON (ed.), *Saints and Their Cults: Studies in Religious Sociology, Folklore, and History* (1983, reprinted 1985). See also JOHN J. DELANEY, *Dictionary of Saints* (1980); and DAVID HUGH FARMER, *The Oxford Dictionary of Saints*, 2nd ed. (1987), on Irish and English saints.

HENRY KAHANE and RENÉE KAHANE, *The Krater and the Grail: Hermetic Sources of the Parzival* (1965, reprinted 1984), analyzes Wolfram von Eschenbach's *Parzival*. For the Arthurian cycles, see P.B. GROUT *et al.* (eds.), *The Legend of Arthur in the Middle Ages* (1983); and ALFRED NUTT, *Studies on the Legend of the Holy Grail: With Especial References to the Hypothesis of Its Celtic Origin* (1888, reissued 1967).

Christian alchemy is described in C.G. JUNG, *Psychology and Alchemy*, 2nd ed. rev. (1968, reprinted 1980; originally published in German, 2nd rev. ed., 1952). Symbolic astronomy and the mutual refiguration of Christian and pagan legends are treated in a 15th-century text, IOAN P. COULIANO (CULIANU), *Eros and Magic in the Renaissance*, trans. from French (1987). On the alchemical researches of Enlightenment scientists, especially physicists and chemists, see FRANCES A. YATES, *The Rosicrucian Enlightenment* (1972, reissued 1986); and BETTY JO TEETER DOBBS, *The Foundations of Newton's Alchemy: or, "The Hunting of the Greene Lyon"* (1975, reprinted 1983).

Two examples of non-Western materials are ROGER BASTIDE, *The African Religions of Brazil: Toward a Sociology of the Interpenetration of Civilizations* (1978; originally published in French, 1960), especially pp. 260–84 on Afro-Brazilian Christianity; and MARC DE CIVRIEUX, *Watunna: An Orinoco Creation Cycle*, trans. from Spanish (1980).

Roles of Christianity: The relation of the Christian community to the world is discussed in ERNST TROELTSCH, *The Social Teaching of the Christian Churches*, 2 vol. (1931, reprinted 1981; originally published in German, 1912), dated in specifics but still one of the most comprehensive and influential studies of this topic; H. RICHARD NIEBUHR, *Christ and Culture* (1951, reprinted 1975); PAUL TILLICH, *Theology of Culture* (1959, reprinted 1978), essays on philosophy, art, literature, and science; and PETER L. BERGER, *The Sacred Canopy: Elements of a Sociological Theory of Religion* (1967, reprinted 1969; U.K. title, *The Social Reality of Religion*, 1969, reissued 1973). Works on various aspects of Christianity's intersection with the world include, on pastoral care, WILLIAM A. CLEBSCH and CHARLES R. JAEKLE, *Pastoral Care in Historical Perspective* (1964, reissued 1983), including excerpts from primary sources in the history of the church; and RONALD L. NUMBERS and DARREL W. AMUNDSEN (eds.), *Caring and Curing: Health and Medicine in the Western Religious Traditions* (1986), a unique and comprehensive presentation by scholars of various faith traditions, with bibliographies; on poverty, MICHEL MOLLAT (ed.), *Études sur l'histoire de la pauvreté*, 2 vol. (1974), a collection of essays on the history of the church's understanding of poverty from the early church to the modern period—each essay with an English abstract; and CARTER LINDBERG, "Through a Glass Darkly: A History of the Church's Vision of the Poor and Poverty, *The Ecumenical Review*, 33(1):37–52 (Jan. 1981); on birth control, JOHN T. NOONAN, JR., *Contraception: A History of Its Treatment by the Catholic Theologians and Canonists*, enlarged ed. (1986); on the concept of love, ANDERS NYGREN, *Agape and Eros*, 2 vol. in 3 (1932–39, reissued 1982; originally published in Swedish, 2 vol., 1930–36); on black theology, GAYRAUD S. WILMORE and JAMES H. CONE (eds.), *Black Theology: A Documentary History, 1966–1979* (1979); and JAMES H. CONE, *For My People: Black Theology and the Black Church* (1984); on liberation theology, DEANE WILLIAM FERM, *Third World Liberation Theologies: An Introductory Survey* (1986); and LEONARDO BOFF and CLODOVIS BOFF, *Introducing Liberation Theology* (1987; originally published in Portuguese, 1986); and, on feminist theology, ROSEMARY RADFORD RUETHER, *Sexism and God-Talk: Toward a Feminist Theology* (1983); and LETTY M. RUSSELL (ed.), *Feminist Interpretation of the Bible* (1985).

Missions: DAVID B. BARRETT (ed.), *World Christian Encyclopedia: A Comparative Study of Churches and Religions in the Modern World* (1982), is comprehensive and indispensable. See also STEPHEN NEILL, GERALD ANDERSON, and JOHN GOODWIN (eds.), *Concise Dictionary of the Christian World Mission* (1971); and DON M. MCCURRY, *World Christianity* (1979–), with 5 volumes appearing by 1987 on the Middle East, eastern Asia, South Asia, Central America and the Caribbean, and Oceania. KENNETH SCOTT LATOURETTE, *A History of the Expansion of Christianity*, 7 vol. (1937–45, reprinted 1971), is a pioneering classic. STEPHEN NEILL, *A History of Christian Missions*, 2nd ed. rev. by OWEN CHADWICK (1986), is a lively, engaging work. WALTER M. ABBOTT (ed.), *The Documents of Vatican II* (1966), includes the relevant texts. POPE PAUL VI, *On Evangelization in the Modern World* (1975), addresses post-Vatican II debates. R. PIERCE BEAVER (ed.), *American Missions in Bicentennial Perspective* (1977), is a collection of interpretive essays. Volumes in the series "Mission Trends," ed. by GERALD H. ANDERSON and THOMAS F. STRANSKY (1974–), include discussions of current issues, evangelization, Third World theologies, North American and European liberation theologies, and Christianity and other religions. See also MARCELLO DE CARVALHO AZEVEDO, *Inculturation and the Challenges of Modernity* (1982). Useful journals include *International Review of Mission* (quarterly); and *International Bulletin of Missionary Research* (quarterly), which annually updates the statistics in the *World Christian Encyclopedia*.

Ecumenism: Introductions to the topic are provided by PAUL A. CROW, JR., *Christian Unity: Matrix for Mission* (1982); NORMAN GOODALL, *The Ecumenical Movement: What It Is and What It Does*, 2nd ed. (1964); ERNST LANGE, *And Yet It Moves: Dream and Reality of the Ecumenical Movement*, trans. from Swedish (1979); JOHN T. MCNEILL, *Unitive Protestantism: The Ecumenical Spirit and Its Persistent Expression*, rev. ed. (1964); and CHARLES CLAYTON MORRISON, *The Unfinished Reformation* (1953). Historical overviews can be found in MARC BOEGNER, *The Long Road to Unity* (1970; originally published in French, 1968); ROBERT MCAFEE BROWN, *The Ecumenical Revolution: An Interpretation of the Catholic-Protestant Dialogue*, rev. and expanded ed. (1969); WILLIAM ADAMS BROWN, *Toward a United Church: Three Decades of Ecumenical Christianity* (1946); SAMUEL MCCREA CAVERT, *The American Churches in the Ecumenical Movement, 1900–1968* (1968), and *Church Cooperation and Unity in America: A Historical Review: 1900–1970* (1970); HAROLD E. FEY (ed.), *The Ecumenical Advance*, 2nd ed. (1986); AUSTIN FLANNERY (ed.), *Vatican Council II: The Conciliar and Post-Conciliar Documents* (1975, reissued 1984), and a companion volume, *Vatican Council II: More Postconciliar Documents* (1982); NORMAN GOODALL, *Ecumenical Progress: A Decade of Change in the Ecumenical Movement, 1961–71* (1972); WILLIAM RICHEY HOGG, *Ecumenical Foundations: A History of the International Missionary Council and Its Nineteenth Century Background* (1952); HARDING MEYER and LUKAS VISCHER (eds.), *Growth in Agreement: Reports and Agreed Statements of Ecumenical Conversations on a World Level* (1984); CONSTANTIN G. PATELOS (ed.), *The Orthodox Church in the Ecumenical Movement: Documents and Statements, 1902–1975* (1978); RUTH ROUSE and STEPHEN NEILL (eds.), *A History of the Ecumenical Movement, 1517–1948*, 3rd ed. (1986); BARRY TILL, *The Churches Search for Unity* (1972); THOMAS F. TORRANCE, "Ecumenism: A Reappraisal of Its Significance, Past, Present and Future," in his *Theology in Reconciliation: Essays Towards Evangelical and Catholic Unity in East and West* (1975); HENRY PITNEY VAN DUSEN, *One Great Ground of Hope: Christian Missions and Christian Unity* (1961); MAURICE VILLAIN, *Unity: A History and Some Reflections* (1963; originally published in French, 3rd rev. and augmented ed., 1961); W.A. VISSER 'T HOOFT, *Memoirs* (1973), and *The Genesis and Formation of the World Council of Churches* (1982); and HANS-RUEDI WEBER, *Asia and the Ecumenical Movement, 1895–1961* (1966).

The Christian Church and non-Christian religions: The most comprehensive and up-to-date survey of Christian attitudes toward the world religions is PAUL F. KNITTER, *No Other Name?* (1985). A wide range of views is reflected in JOHN HICK and BRIAN HEBBLETHWAITE (eds.), *Christianity and Other Religions: Selected Readings* (1980); and GERALD H. ANDERSON and THOMAS F. STRANSKY (eds.), *Christ's Lordship and Religious Pluralism* (1981). The classic modern statement of a conservative position is that of HENDRICK KRAEMER, *The Christian Message in a Non-Christian World*, 3rd ed. (1956, reprinted 1969). S.J. SAMARTHA (ed.), *Faith in the Midst of Faiths: Reflections on Dialogue in Community* (1977), was produced by the World Council of Churches. ARNULF CAMPS, *Partners in Dialogue: Christianity and Other World Religions* (1983; originally published in Dutch, 3 vol., 1976–78); and HANS KÜNG *et al.*, *Christianity and the World Religions: Paths of Dialogue with Islam, Hinduism, and Buddhism* (1986; originally published in German, 1984), represent different contemporary Roman Catholic standpoints. The pluralistic option is expressed in, for example, WILFRED CANTWELL SMITH, *Towards a World Theology: Faith and the Comparative History of Religion* (1981); JOHN HICK, *God Has Many Names* (1982); and JOHN HICK and PAUL F. KNITTER (eds.), *The Myth of Christian Uniqueness: Toward a Pluralistic Theology of Religions* (1987).

(M.E.M./H.Cha./J.J.Pe./E.W.B./M.H.S./L.M.Ö./J.N.D.K./J.Hi./B.J.McG./L.E.S./C.H.Li./W.R.H./P.A.C.)

Chungking (Chongqing)

Chungking (Wade-Giles romanization: Ch'ung-ch'ing; Pinyin: Chongqing) is the largest city and leading river port and industrial centre of southwestern China. It is located 1,400 miles (2,250 kilometres) from the sea, at the confluence of the Yangtze and Chia-ling rivers. The city proper includes the Old City and adjacent areas, while the much larger Chungking Municipality (Ch'ung-ch'ing Shih) comprises several counties and a number of lesser cities surrounding Chungking city proper. The municipality, created out of the eastern portion of Szechwan Province in 1997, is a province-level entity that is under the direct administration of the central government; with an area of 8,900 square miles (23,000 square kilometres), it is the largest and most populous of China's four province-level municipalities. The city was named Ch'ung-ch'ing ("Double-Blessed") in 1188 under the Nan (Southern) Sung dynasty (AD 1127–1279) because of its commanding position between the cities of Shun-ch'ing (modern Nan-ch'ung) to the north and Shao-ch'ing (modern P'eng-shui) to the south.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

The city site. Chungking is built on and around Mount Chin-pi (Chin-pi Shan), a hilly promontory of red Jurassic sandstone and shale, which reaches a maximum elevation of about 900 feet (275 metres) above sea level. The promontory is bounded on the north by the Chia-ling River (Chia-ling Chiang), with the industrial area of Chiang-pei on its north bank, and on the east and south by the Yangtze. Other hills, southern offshoots of the Hua-ying Mountains (Hua-ying Shan), rise in the city's outskirts and suburbs.

Climate. Chungking is noted for its mild winters and hot, humid summers. It is shielded from the cold northern winds by the Tsinling Mountains and has little or no frost or ice in winter; the mean temperatures in January and February, the only cool months, are 47° F (8° C) and 50° F (10° C), respectively. Summer, which lasts from May through September, is hot and humid; the August mean temperature is 84° F (29° C), and on many days the high temperature exceeds 100° F (38° C). The remaining months are warm, with mean temperatures ranging between 58° and 67° F (14° and 19° C).

The bulk of rain falls from April through October; the average annual total is about 43 inches (1,087 millimetres). Because of the high humidity, fog and mist are particularly heavy. From October to April the city is perpetually blanketed by fog, which hampers inland navigation, aviation, and local traffic. Chungking's climate has earned the city the nickname "furnace of the Yangtze." The aptness of this name has only increased under the conditions of modernity: contaminated by soot, carbon dioxide, and acid rain, the atmosphere of Chungking is among the most polluted of any city in China.

The city plan. *Layout.* The Old City of Chungking (formerly surrounded by a city wall and gates, of which only the names now remain) occupies the eastern third of the rocky promontory and covers an area of about 28 square miles (73 square kilometres). The south and east slopes facing the waterfront form the "lower city," while the remainder is the "upper city." An east–west avenue runs through the middle of each of these areas, and a third runs atop the spine of the promontory's ridge. Cross streets are narrower and often winding; following the topography of the hill, some of them go up and down in flights of hundreds of steps. Chungking's main business district is located around the Liberation Monument (Chieh-fang Pei) in the centre of the Old City.

New districts and suburbs

The new sections of the city on the western part of the promontory spread far along the banks of the two rivers, covering an area considerably larger than the Old City. During World War II the offices of the Nationalist government were located there, and they are now the sites of government office buildings and of museums and exhibition halls. The city has grown so much that the incorporation of numerous industrial towns and suburban communities has extended the city limits to Pei-p'ei in the north and to Pai-shih-i in the southwest. Equally important are the suburban areas on the south shore of the Yangtze. In former times, ferries were the only means by which the rivers could be crossed; now they also may be crossed by way of the Chia-ling Bridge (1966) to the northwest and the Chungking Yangtze Bridge (1980) to the south. A cableway across the Chia-ling River links the Old City with Chiang-pei. The spacious gardens and beautiful residences of the suburban areas contribute much to relieving the crowded conditions of the Old City.

Housing. Before World War II Chungking was a city of narrow streets and crowded housing. Streets and lanes followed the contours of the hills. The houses were constructed of bamboo, wood, or thatch in the poorer residential areas and of brick in the wealthier areas. In all areas there was a high degree of congestion. A vigorous modernization program was introduced when the city became the seat of the Nationalist government. Part of the city wall was demolished to make way for new streets, and existing streets were graded and widened. The tremendous demand for housing created by an influx of government workers and refugees led to the rapid expansion of the sections west of the Old City.

From 1938 to 1942 Chungking was heavily bombarded by the Japanese, causing massive destruction in the city. Parts of the wall and virtually all of the city's historic monuments and temples were damaged or destroyed. Because of the destruction the new Communist government (which came to power in 1949) had little difficulty in carrying forward the tasks of modernization and expansion after the war. Modern buildings now stand throughout the city. In the northern suburbs and adjacent areas large buildings provide living quarters for workers and accommodations for factories and workshops. The large brick apartments, generally four to six stories high, are surrounded by trees and vegetable gardens. Yet Chungking remains a city of

Residential area and (right) the town hall in Chungking.

striking contrasts. Houses of traditional design, blackened by weather, are still to be found on steep hills and along the highways to the suburbs. In many places bamboo structures still line the river bluffs.

Resorts and spas

Outlying suburbs. In contrast to the congested conditions in the city and the industrial districts, the outlying suburbs have a number of delightful resorts and spas. Among the scenic spots on the south shore are the temple in honour of Empress Yü, consort of the Hsia dynasty emperor of the same name, on Mount Tu; the wooded summer resorts of Ch'ing-shui-ch'i ("Clear Water Creek") and Yang-t'ien-wo ("Sky-gazing Hollow") on Mount Huang; and Nan-wen-ch'üan ("South Hot Springs"), which has delightful retreats at Hua-ch'i ("Flower Creek") and Hu-hsiao-k'ou ("Tiger Roar Gap"). A short distance north of the city are the springs of Ko-lo-shan. Farther up the Chia-ling River at Pei-p'ei are the Chin-yün Shih Temple, the celebrated retreat of the Sung dynasty savant Feng Chin-yün, and Pei-wen-ch'üan ("North Hot Springs"), reputedly superior to the South Hot Springs because its water is warmer in winter and cooler in summer.

THE PEOPLE

Before the war with Japan, Chungking had fewer than 250,000 inhabitants. From 1938 onward, people from the Japanese-occupied coastal provinces flocked to the wartime capital at an astonishing rate. A part of Chungking's population increase since 1938 has consisted of government workers, factory personnel, and refugees from other provinces. (In the late 1940s, however, the city's population decreased temporarily with the return of people to the coastal provinces.) The influx of people from downriver has contributed to turning formerly parochial Chungking into a cosmopolitan city; the number of people living in the city proper alone is now many times greater than the population of the Old City before the war. The Szechwan dialect, despite its heavy accent and many regional slang words, is quite intelligible to speakers of Mandarin.

THE ECONOMY

Industry. As early as the middle of the Ming dynasty (1368–1644) workshops for spinning, weaving, silk reeling, and brewing were established in Chungking. The city was opened to foreign trade in 1890, and two metal mills were set up a year later. By 1905 Chungking had spinning and weaving mills, silk-reeling mills, and glassmaking and cigarette plants.

Industrial growth

The foundations of Chungking's modern industry were laid between 1938 and 1945, when factories transplanted from the coastal provinces began production under the Nationalist government; and because coal, iron, and other resources were nearby, industry rapidly expanded. Considerable industrial development was undertaken by the Communist government after 1949. By the late 20th century Chungking had become one of the largest and fastest growing industrial centres in southwestern China.

The city's enormous complex of integrated iron and steel plants is among China's largest facilities. Ore is mined at Ch'i-chiang (in the southern part of the municipality) and at Wei-yüan (a short distance west of Nei-chiang). Coal is mined at several locations in the municipality, including Chiang-pei, Pei-p'ei, Pa-hsien, Pi-shan, and Ho-ch'uan. Oil transported from a major oil field just to the west at Tzu-kung and by pipeline from a field to the north supplies Chungking's oil refinery. Power-generating capacity was greatly enlarged with the completion of the Shih-tze-t'an hydroelectric station on the Lung-ch'i River, northeast of the city.

Other important heavy industries include machine, farm tool, and weapons and munitions factories; automobile, motorcycle, truck, and motor-coach manufacturing plants; and chemical and fertilizer plants (manufacturing soap, candles, acid and caustic soda, fertilizers, plastics, and chemical fibres). The city also has a copper refinery, alcohol plants (making gasoline substitutes), rubber reconditioning plants, and pharmaceutical manufacturing. In light industries Chungking leads the southwest. Noteworthy are the cotton, silk, paper, and leather industries, as well as flour mills, dyeing factories, and vegetable-oil and food-processing plants. Chungking is also noted for its handicrafts, especially lacquer ware and ceramics. More recently, the central government and municipal authorities have built large industrial parks and have established high-technology zones specializing in the software industry. Domestic- and foreign-owned companies are located in both types of areas.

Trade. Chungking is the focal point of trade and transport of Szechwan and the hinterland provinces of Shensi, Yunnan, and Kweichow, as well as the autonomous region of Tibet. Before World War II Chungking imported large quantities of consumer goods from downriver or from abroad, but rapid industrialization brought self-sufficiency in consumer goods to Szechwan and the interior provinces. Since 1979 its port—along with several others on the Yangtze—has been open for direct foreign trade, increasing the city's importance as an international trade centre. Chungking is a major oil port, and other exports to downriver provinces and abroad include rolled steel, chemicals, raw silk, goatskin, wool, hides, hog bristles, salt, sugar, tobacco, tung oil, jute, wax, canned foods, medicinal herbs, rhubarb, and musk.

Transportation. Since 1949 automobiles, motorcycles, motorbikes, bicycles, buses, and taxis, have replaced chairs on bamboo poles and rickshas as the principal means of transport in Chungking. Cable tramways provide cheap and convenient transport over the steep hills.

Chungking is served by two great rivers, the Yangtze and the Chia-ling, and is the leading port of southwestern China. As a result of extensive work carried out since the 1950s—including dredging, clearing shoals, and installing buoys and signals—navigation through the Yangtze Gorges to the sea was rendered easy and safe. Steamers

now make a round trip between Han-k'ou (part of Wu-han) in eastern Hupeh Province and Chungking in less than a week. Above Chungking smaller steamers are able to go up to I-pin on the Yangtze (and beyond to Chia-ting on the Min River) and up to Nan-ch'ung on the Chia-ling. Above these points, smaller vessels can navigate beyond Ch'eng-tu to Kuan-hsien and Mao-hsien on the Min and to Lüeh-yang in southern Shensi on the Chia-ling.

Construction began in 1994 on the massive Three Gorges Project, the centrepiece of which is an enormous dam and hydroelectric generating facility on the Yangtze River several hundred miles east of Chungking. When the project is completed, it will create a huge reservoir that will stretch westward to Chungking and enable oceangoing vessels to reach the city.

Chungking's railroad system developed rapidly after 1949. The Chungking–Ch'eng-tu railroad, completed in 1952, is the vital link between the Ch'eng-tu Plain and the Yangtze; a southern spur extends through Tzu-kung and I-pin. The Ch'eng-tu–Pao-chi line, completed four years later, connects the city with the Lunghai Railroad and the entire Northwest, as well as with Wu-han in Hupeh Province and a major north-south line; the Chungking–An-k'ang railway also directly links the city with Wu-han. All of the lines serving the city have been electrified. The Chungking–Kuei-yang railroad not only connects Chungking with the province of Kweichow to the south but also joins other lines in Yunnan and Kwangsi running to the Vietnamese border.

The first roads for wheeled traffic in the city were built in 1933. As a result of work begun during World War II, Chungking is now the hub of an extensive network of highways which allows access to most parts of the country. Major arterials lead south to Kuei-yang (303 miles), northeast to Wan-hsien (258 miles), and northwest to Ch'eng-tu (275 miles). The Chungking Yangtze Bridge carries highway traffic across the river from the southern Kuei-yang highway to the northern part of the city. An air terminal, located at Pai-shih-i about 17 miles west of the city, provides regular flights to major cities throughout China. The Chiang-pei Airport, located 14 miles north of the city, was completed in 1990 and expanded and improved in 2000 to meet international standards.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Chungking's municipal government is part of the hierarchical structure of the Chinese government that extends from the national organization, through the provincial apparatus, to the municipal and, ultimately, neighbourhood levels. Paralleling this governmental structure is that of the Chinese Communist Party (CCP). As in all of China, real power in Chungking is held by the local CCP, but local government institutions perform various formal functions. The Chungking Municipal People's Congress, the formal governmental decision-making body, follows the guidance of the local CCP in issuing administrative orders, collecting taxes, determining the budget, and implementing economic plans. Under the direction of the local CCP, a standing committee of the Municipal People's Congress recommends policy decisions and oversees the operation of municipal government. Executive authority is formally assigned to the Chungking People's Government, the officers of which are elected by the congress. The local government consists of a mayor, vice mayors, and numerous bureaus in charge of public security, the judicial system, and other civil, economic, social, and cultural affairs.

Municipal government and the CCP

Administratively the city is divided into a number of districts (*ch'ü*), each of which has a mayor. At the next lower level are police substations and street mayors that handle civil affairs in the same subareas. Neighbourhood street committees perform the auxiliary functions of mediating disputes, propagating legal orders, and promoting sanitation and welfare. These committees are quasi-official administrations, consolidated under CCP leadership and covering blocks of streets of varying sizes.

Public utilities. Although an electric-light plant was established in the early 1900s, it was not until the late 1920s and early 1930s that a modernization drive was launched by local leaders in Chungking to improve living conditions. Demolition of the city walls was initiated, streets were widened, and a piped water system and a telephone exchange were introduced. Yet even during the 1940s sanitation and public hygiene were still poor. The city had a large rat population, opium smoking in homes and inns was widespread, and lice-ridden waifs and beggars were a familiar sight. But because of energetic measures carried out since 1949, including the installation of a modern sewer system, these conditions belong to the past. Chungking has now achieved a high degree of cleanliness, although air pollution has become a problem.

Health. Chungking has a considerable number of hospitals. The major share of medical care, however, is provided by clinics and health stations that are operated by neighbourhood street committees. These clinics are equipped with a limited number of beds and are staffed by physicians. Western-style medicine is combined with traditional herb medicine and acupuncture. Family planning is practiced under the government's policy of one child per family, and contraceptives are free. Because the government recognizes that there still is a shortage of medical facilities, it places great emphasis on the drive for physical fitness.

Education. Since 1949 the number of schools at all levels—kindergartens, primary schools, middle schools, and colleges—has increased. The growth of kindergartens, which were little known in prewar years, has enabled many women to obtain proper care for their children and thus become part of the workforce. The government has attached great importance to the establishment of teacher-training schools, vocational-technical schools, and part-time agricultural middle schools.

Institutions of higher learning

The Chungking University (founded in 1929) offers its students a comprehensive range of studies. Other institutions of higher learning include the Southwest Political Science and Law College, the Chungking Institute of Medicine, the Chungking Construction Engineering College, the Southwestern Institute of Agriculture, the Szechwan Institute of Fine Arts, and the Southwest College of Education. The Chungking Library and the Chungking Municipal Museum are among the leading cultural centres in the city.

CULTURAL LIFE

Sports and recreation are dominant features of Chungking's cultural life. The Ta-t'ien-wan Stadium, the city's main sports centre, offers a football (soccer) field; volleyball, basketball, and tennis courts; a track-and-field playground; and a parachute tower. The stadium has a capacity of 100,000. Numerous parks, both in the Old City and in outlying areas, attract large numbers of visitors. Of particular appeal are the hot springs, which are open year-round. South of the city, among well-kept gardens with lakes and pavilions, are the sulfurous springs of Nan-wen-ch'üan Park. To the north of the city are the well-known hot springs of Pei-wen-ch'üan Park along the Chia-ling River. Visitors come to relax, often soaking for hours in one of the numerous baths filled with warm mineral water, or they swim in one of the three Olympic-sized pools, which are also fed by the hot springs.

A noteworthy feature of Chungking's cultural life is its distinctive Szechwan cuisine. This highly spiced food is characterized mainly by the use of hot peppers as well as by such delicacies as tree ears, black mushrooms, and fresh bamboo shoots and peanuts.

History

THE EARLY PERIOD

According to ancient accounts Chungking was the birthplace of the consort of Emperor Yü of the legendary Hsia dynasty, about 4,000 years ago. In the 11th century BC, under the Western Chou dynasty, the region surrounding Chungking became a feudal state known as Pa. In the 5th century BC, Pa established relations with the mid-Yangtze kingdom of Ch'u. It was later incorporated into the Ch'in empire. By the mid-3rd century AD the region became part of the kingdom of Shu and was totally independent of northern and central China.

The swing of the historical pendulum—in which the city's status alternated between being ruled by an empire in northern China, forming part of an empire in central China, and detaching itself to become independent of both northern and central China—continued throughout subsequent centuries. The city finally became an integral part of the unified Chinese empire, first under the Ming dynasty (1368–1644), and then under the Ch'ing, or Manchu, dynasty (1644–1911/12).

The city walls

The first substantial city wall was constructed around 250 BC. It was repaired and expanded during the 3rd century AD and rebuilt with solid stone in 1370. In the 1630s, at the end of the Ming dynasty, the rebellion of Chang Hsien-chung subjected Chungking to plunder, slaughter, and destruction. The city wall was restored in 1663. Some five miles in circumference, it had a total of 17 gates: eight gates remained closed on the advice of geomancers (practitioners of divination by means of figures or lines), while nine were open to traffic. Additional work was done to strengthen the city wall in 1760.

THE MODERN PERIOD

Chungking was opened to British trade in 1890, but navigational difficulties on the Yangtze delayed steamer traffic for more than a decade. Meanwhile, the Treaty of Shimonoseki (1895), which concluded the first Sino-Japanese War (1894–95), gave Japan the right to establish a concession. Accordingly, in 1901, when British trade opened, a Japanese concession was established at Wang-chia-to on the south shore of the Yangtze. This concession lasted until 1937, when it was abandoned by Japan at the outbreak of war.

Chungking, along with the provincial capital, Ch'eng-tu, played a major role in the overthrow of the Manchus in the revolution of 1911; many patriots of the region joined the revolutionary party of the Chinese Nationalist leader Sun Yat-sen. Despite such progressive trends and a nominal allegiance to the central government, Chungking remained in the grip of regional separatism.

Capital of the Nationalist government

In 1938, however, when war again broke out with Japan, Chungking became the capital of the Nationalist government. Hundreds of government offices were moved to the city from Nanking, along with the diplomatic missions of foreign powers; and tens of thousands of people came from coastal provinces, bringing with them arsenals, factories, and schools. Friendly powers, too, rushed supplies to Chungking to bolster China's war effort. Despite the Japanese bombings, the morale of its population—at the time more than 1,000,000—was high. Chiang Kai-shek's failure to control inflation and corruption, however, caused the war effort to falter from 1942 onward. In 1946, on the eve of the renewed civil war against the Communists, the Nationalist capital returned to Nanking. Three years later, in April 1949, Nanking fell. The Nationalist government fled to Canton and then once again—for less than two months—to Chungking (October to December 1949). When the Nationalists fled to Taiwan in December, the Communist victory on the mainland was complete.

Shortly after the Communist takeover in 1949, repair of the war damage began, and expansion of the city's industrial base, established in the early 20th century, was vigorously pursued. Despite the years lost during the Great Leap Forward (1958–60) and the Cultural Revolution (1966–76), the city, nonetheless, succeeded in carrying out extensive modernization projects and significantly raised the standard of living. Now the largest province-level municipality in the country and the economic centre of the southwest, Chungking is playing an important part in the government's plan to develop the interior of the country along the lines of the more economically dynamic coastal regions.

Churchill

Sir Winston Churchill—author, orator, and statesman—led Great Britain from the brink of defeat to victory as wartime prime minister from 1940 to 1945. After a sensational rise to prominence in national politics before World War I, he acquired a reputation for erratic judgment in the war itself and in the decade that followed. Politically suspect in consequence, he was a lonely figure until his response to Adolf Hitler's challenge brought him to leadership of a national coalition in 1940. With Franklin D. Roosevelt and Joseph Stalin he shaped Allied strategy in World War II, and after the breakdown of the alliance he alerted the West to the expansionist threat of the Soviet Union. He led the Conservative Party back to office in 1951 and remained prime minister until 1955, when ill health forced his resignation.

Churchill was born on Nov. 30, 1874, prematurely, at Blenheim Palace, Oxfordshire, and was christened Winston Leonard Spencer Churchill. In his veins ran the blood of both of the English-speaking peoples whose unity, in peace and war, it was to be a constant purpose of his to promote. Through his father, Lord Randolph Churchill, the meteoric Tory politician, he was directly descended from John Churchill, 1st duke of Marlborough, the hero of the wars against Louis XIV of France in the early 18th century. His mother, Jennie Jerome, a noted beauty, was the daughter of a New York financier and horse racing enthusiast, Leonard W. Jerome.

Churchill, photographed by Yousuf Karsh, 1941.

The young Churchill passed an unhappy and sadly neglected childhood, redeemed only by the affection of Mrs. Everest, his devoted nurse. At Harrow his conspicuously poor academic record seemingly justified his father's decision to enter him into an army career. It was only at the third attempt that he managed to pass the entrance examination to the Royal Military College, now Academy, Sandhurst, but, once there, he applied himself seriously and passed out (graduated) 20th in a class of 130. In 1895, the year of his father's tragic death, he entered the 4th Hussars. Initially the only prospect of action was in Cuba, where he spent a couple of months of leave reporting the Cuban war of independence from Spain for the *Daily Graphic* (London). In 1896 his regiment went to India, where he saw service as both soldier and journalist on the North-West Frontier (1897). Expanded as *The Story of the Malakand Field Force* (1898), his dispatches attracted such wide attention as to launch him on the career of authorship that he intermittently pursued throughout his life. In 1897–98 he wrote *Savrola* (1900), a Ruritanian romance, and got himself attached to Lord Kitchener's Nile expeditionary force in the same dual role of soldier and correspondent. *The River War* (1899) brilliantly describes the campaign.

Early career as a soldier and journalist

POLITICAL CAREER BEFORE 1939

The five years after Sandhurst saw Churchill's interests expand and mature. He relieved the tedium of army life in India by a program of reading designed to repair the deficiencies of Harrow and Sandhurst, and in 1899 he resigned his commission to enter politics and make a living by his pen. He first stood as a Conservative at Oldham, where he lost a by-election by a narrow margin, but found quick solace in reporting the South African War for *The Morning Post* (London). Within a month after his arrival in South Africa he had won fame for his part in rescuing an armoured train ambushed by Boers, though at the price of himself being taken prisoner. But this fame was redoubled when less than a month later he escaped from military prison. Returning to Britain a military hero, he laid siege again to Oldham in the election of 1900. Churchill succeeded in winning by a margin as narrow as that of his previous failure. But he was now in Parliament and, fortified by the £10,000 his writings and lecture tours had earned for him, was in a position to make his own way in politics.

A self-assurance redeemed from arrogance only by a kind of boyish charm made Churchill from the first a notable House of Commons figure, but a speech defect, which he never wholly lost, combined with a certain psychological inhibition to prevent him from immediately becoming a master of debate. He excelled in the set speech, on which he always spent enormous pains, rather than in the impromptu; Lord Balfour, the Conservative leader, said of him that he carried "heavy but not very mobile guns." In matter as in style he modeled himself on his father, as his admirable biography, *Lord Randolph Churchill* (1906; revised edition 1952), makes evident, and from the first he wore his Toryism with a difference, advocating a fair, negotiated peace for the Boers and deploring military mismanagement and extravagance.

As Liberal minister. In 1904 the Conservative government found itself impaled on a dilemma by Colonial Secretary Joseph Chamberlain's open advocacy of a tariff. Churchill, a convinced free trader, helped to found the Free Food League. He was disavowed by his constituents and became increasingly alienated from his party. In 1904 he joined the Liberals and won renown for the audacity of his attacks on Chamberlain and Balfour. The radical elements in his political makeup came to the surface under the influence of two colleagues in particular, John Morley, a political legatee of W.E. Gladstone, and David Lloyd George, the rising Welsh orator and firebrand. In the ensuing general election in 1906 he secured a notable victory in Manchester and began his ministerial career in the new Liberal government as undersecretary of state for the colonies. He soon gained credit for his able defense of the policy of conciliation and self-government in South Africa. When the ministry was reconstructed under Prime Minister Herbert H. Asquith in 1908, Churchill was promoted to president of the Board of Trade, with a seat in the Cabinet. Defeated at the ensuing by-election in Manchester, he won an election at Dundee. In the same year he married the beautiful Clementine Hozier; it was a marriage of unbroken affection that provided a secure and happy background for his turbulent career.

Attacks on Conservatives

At the Board of Trade, Churchill emerged as a leader in the movement of Liberalism away from laissez-faire toward social reform. He completed the work begun by his predecessor, Lloyd George, on the bill imposing an

eight-hour maximum day for miners. He himself was responsible for attacking the evils of "sweated" labour by setting up trade boards with power to fix minimum wages and for combating unemployment by instituting state-run labour exchanges.

When this Liberal program necessitated high taxation, which in turn provoked the House of Lords to the revolutionary step of rejecting the budget of 1909, Churchill was Lloyd George's closest ally in developing the provocative strategy designed to clip the wings of the upper chamber. Churchill became president of the Budget League, and his oratorical broadsides at the House of Lords were as lively and devastating as Lloyd George's own. Indeed Churchill, as an alleged traitor to his class, earned the lion's share of Tory animosity. His campaigning in the two general elections of 1910 and in the House of Commons during the passage of the Parliament Act of 1911, which curbed the House of Lords' powers, won him wide popular acclaim.

Home secretary

In the Cabinet his reward was promotion to the office of home secretary. Here, despite substantial achievements in prison reform, he had to devote himself principally to coping with a sweeping wave of industrial unrest and violent strikes. Upon occasion his relish for dramatic action led him beyond the limits of his proper role as the guarantor of public order. For this he paid a heavy price in incurring the long-standing suspicion of organized labour.

In 1911 the provocative German action in sending a gunboat to Agadir, the Moroccan port to which France had claims, convinced Churchill that in any major Franco-German conflict Britain would have to be at France's side. When transferred to the Admiralty in October 1911, he went to work with a conviction of the need to bring the navy to a pitch of instant readiness. His first task was the creation of a naval war staff. To help Britain's lead over steadily mounting German naval power, Churchill successfully campaigned in the Cabinet for the largest naval expenditure in British history. Despite his inherited Tory views on Ireland, he wholeheartedly embraced the Liberal policy of Home Rule, moving the second reading of the Irish Home Rule Bill of 1912 and campaigning for it in the teeth of Unionist opposition. Although, through his friendship with F.E. Smith (later 1st earl of Birkenhead) and Austen Chamberlain, he did much to arrange the compromise by which Ulster was to be excluded from the immediate effect of the bill, no member of the government was more bitterly abused—by Tories as a renegade and by extreme Home Rulers as a defector.

During World War I. War came as no surprise to Churchill. He had already held a test naval mobilization. Of all the Cabinet ministers he was the most insistent on the need to resist Germany. On Aug. 2, 1914, on his own responsibility, he ordered the naval mobilization that guaranteed complete readiness when war was declared. The war called out all of Churchill's energies. In October 1914, when Antwerp was falling, he characteristically rushed in person to organize its defense. When it fell the public saw only a disillusioning defeat, but in fact the prolongation of its resistance for almost a week enabled the Belgian Army to escape and the crucial Channel ports to be saved. At the Admiralty, Churchill's partnership with Adm. Sir John Fisher, the first sea lord, was productive both of dynamism and of dissension. In 1915, when Churchill became an enthusiast for the Dardanelles expedition as a way out of the costly stalemate on the Western Front, he had to proceed against Fisher's disapproval. The campaign aimed at forcing the straits and opening up direct communications with Russia. When the naval attack failed and was called off on the spot by Adm. J.M. de Robeck, the Admiralty war group and Asquith both supported de Robeck rather than Churchill. Churchill came under heavy political attack, which intensified when Fisher resigned. Preoccupied with departmental affairs, Churchill was quite unprepared for the storm that broke about his ears. He had no part at all in the maneuvers that produced the first coalition government and was powerless when the Conservatives, with the sole exception of Sir William Maxwell Aitken (soon Lord Beaverbrook), insisted on his being demoted from the Admiralty to the duchy of Lancaster. There he was given special responsibility for the Gallipoli Campaign (a land assault at the straits) without, however, any powers of direction. Reinforcements were too few and too late; the campaign failed and casualties were heavy; evacuation was ordered in the autumn.

The Dardanelles Campaign

In November 1915 Churchill resigned from the government and returned to soldiering, seeing active service in France as lieutenant colonel of the 6th Royal Scots Fusiliers. Although he entered the service with zest, army life did not give full scope for his talents. In June 1916, when his battalion was merged, he did not seek another command but instead returned to Parliament as a private member. He was not involved in the intrigues that led to the formation of a coalition government under Lloyd George, and it was not until 1917 that the Conservatives would consider his inclusion in the government. In March 1917 the publication of the Dardanelles commission report demonstrated that he was at least no more to blame for the fiasco than his colleagues.

Even so, Churchill's appointment as minister of munitions in July 1917 was made in the face of a storm of Tory protest. Excluded from the Cabinet, Churchill's role was almost entirely administrative, but his dynamic energies thrown behind the development and production of the tank (which he had initiated at the Admiralty) greatly speeded up the use of the weapon that broke through the deadlock on the Western Front. Paradoxically, it was not until the war was over that Churchill returned to a service department. In January 1919 he became secretary of war. As such he presided with surprising zeal over the cutting of military expenditure. The major preoccupation of his tenure in the War Office was, however, the Allied intervention in Russia. Churchill, passionately anti-Bolshevik, secured from a divided and loosely organized Cabinet an intensification and prolongation of the British involvement beyond the wishes of any major group in Parliament or the nation—and in the face of the bitter hostility of labour. And in 1920, after the last British forces had been withdrawn, Churchill was instrumental in having arms sent to the Poles when they invaded the Ukraine.

Appointment to the Colonial Office

In 1921 Churchill moved to the Colonial Office, where his principal concern was with the mandated territories in the Middle East. For the costly British forces in the area he substituted a reliance on the air force and the establishment of rulers congenial to British interests; for this settlement of Arab affairs he relied heavily on the advice of T.E. Lawrence. For Palestine, where he inherited conflicting pledges to Jews and Arabs, he produced in 1922 the White Paper that confirmed Palestine as a Jewish national home while recognizing continuing Arab rights. Churchill never had departmental responsibility for Ireland, but he progressed from an initial belief in firm, even ruthless, maintenance of British rule to an active role in the negotiations that led to the Irish treaty of 1921. Subsequently, he gave full support to the new Irish government.

In the autumn of 1922 the insurgent Turks appeared to be moving toward a forcible reoccupation of the Dardanelles neutral zone, which was protected by a small British force at Chanak (now Çanakkale). Churchill was foremost in urging a firm stand against them, but the handling of the issue by the Cabinet gave the public impression that a major war was being risked for an inadequate cause and on insufficient consideration. A political debacle ensued that brought the shaky coalition government down in ruins, with Churchill as one of the worst casualties. Gripped by a sudden attack of appendicitis, he was not able to appear in public until two days before the election, and then only in a wheelchair. He was defeated humiliatingly by more than 10,000 votes. He thus found himself, as he said, all at once "without an office, without a seat, without a party, and even without an appendix."

In and out of office, 1922–29. In convalescence and political impotence Churchill turned to his brush and his pen. His painting never rose above the level of a gifted amateur's, but his writing once again provided him with the financial base his independent brand of politics required. His autobiographical history of the war, *The World Crisis,* netted him the £20,000 with which he purchased Chartwell, henceforth his country home in Kent. When

he returned to politics it was as a crusading anti-Socialist, but in 1923, when Stanley Baldwin was leading the Conservatives on a protectionist program, Churchill stood, at Leicester, as a Liberal free trader. He lost by approximately 4,000 votes. Asquith's decision in 1924 to support a minority Labour government moved Churchill farther to the right. He stood as an "Independent Anti-Socialist" in a by-election in the Abbey division of Westminster. Although opposed by an official Conservative candidate—who defeated him by a hairbreadth of 43 votes—Churchill managed to avoid alienating the Conservative leadership and indeed won conspicuous support from many prominent figures in the party. In the general election in November 1924 he won an easy victory at Epping under the thinly disguised Conservative label of "Constitutionalist." Baldwin, free of his flirtation with protectionism, offered Churchill, the "constitutionalist free trader," the post of chancellor of the Exchequer. Surprised, Churchill accepted; dumbfounded, the country interpreted it as a move to absorb into the party all the right-of-centre elements of the former coalition.

Chancellor of the Exchequer under Baldwin

In the five years that followed, Churchill's early liberalism survived only in the form of advocacy of rigid laissez-faire economics; for the rest he appeared, repeatedly, as the leader of the diehards. He had no natural gift for financial administration, and though the noted economist John Maynard Keynes criticized him unsparingly, most of the advice he received was orthodox and harmful. His first move was to restore the gold standard, a disastrous measure, from which flowed deflation, unemployment, and the miners' strike that led to the general strike of 1926. Churchill offered no remedy except the cultivation of strict economy, extending even to the armed services. Churchill viewed the general strike as a quasi-revolutionary measure and was foremost in resisting a negotiated settlement. He leaped at the opportunity of editing the *British Gazette,* an emergency official newspaper, which he filled with bombastic and frequently inflammatory propaganda. The one relic of his earlier radicalism was his partnership with Neville Chamberlain as minister of health in the cautious expansion of social services, mainly in the provision of widows' pensions.

In 1929, when the government fell, Churchill, who would have liked a Tory-Liberal reunion, deplored Baldwin's decision to accept a minority Labour government. The next year an open rift developed between the two men. On Baldwin's endorsement of a Round Table Conference with Indian leaders, Churchill resigned from the shadow cabinet and threw himself into a passionate, at times almost hysterical, campaign against the Government of India bill (1935) designed to give India dominion status.

Exclusion from office, 1929–39. Thus, when in 1931 the National Government was formed, Churchill, though a supporter, had no hand in its establishment or place in its councils. He had arrived at a point where, for all his abilities, he was distrusted by every party. He was thought to lack judgment and stability and was regarded as a guerrilla fighter impatient of discipline. He was considered a clever man who associated too much with clever men—Birkenhead, Beaverbrook, Lloyd George—and who despised the necessary humdrum associations and compromises of practical politics.

The biography of Marlborough

In this situation he found relief, as well as profit, in his pen, writing, in *Marlborough: His Life and Times,* a massive rehabilitation of his ancestor against the criticisms of the 19th-century historian Thomas Babington Macaulay. But overriding the past and transcending his worries about India was a mounting anxiety about the growing menace of Hitler's Germany. Before a supine government and a doubting opposition, Churchill persistently argued the case for taking the German threat seriously and for the need to prevent the Luftwaffe from securing parity with the Royal Air Force. In this he was supported by a small but devoted personal following, in particular the gifted, curmudgeonly Oxford physics professor Frederick A. Lindemann (later Lord Cherwell), who enabled him to build up at Chartwell a private intelligence centre the information of which was often superior to that of the government. When Baldwin became prime minister in 1935, he persisted in excluding Churchill from office but gave him the exceptional privilege of membership in the secret committee on air-defense research, thus enabling him to work on some vital national problems. But Churchill had little success in his efforts to impart urgency to Baldwin's administration. The crisis that developed when Italy invaded Ethiopia in 1935 found Churchill ill prepared, divided between a desire to build up the League of Nations around the concept of collective security and the fear that collective action would drive Benito Mussolini into the arms of Hitler. The Spanish Civil War (1936–39) found him convinced of the virtues of nonintervention, first as a supporter and later as a critic of Francisco Franco. Such vagaries of judgment in fact reflected the overwhelming priority he accorded to one issue—the containment of German aggressiveness. At home there was one grievous, characteristic, romantic misreading of the political and public mood, when, in Edward VIII's abdication crisis of 1936, he vainly opposed Baldwin by a public championing of the King's cause.

When Neville Chamberlain succeeded Baldwin, the gulf between the Cassandra-like Churchill and the Conservative leaders widened. Repeatedly the accuracy of Churchill's information on Germany's aggressive plans and progress was confirmed by events; repeatedly his warnings were ignored. Yet his handful of followers remained small; politically, Chamberlain felt secure in ignoring them. As German pressure mounted on Czechoslovakia, Churchill without success urged the government to effect a joint declaration of purpose by Great Britain, France, and the Soviet Union. When the Munich Agreement with Hitler was made in September 1938, sacrificing Czechoslovakia to the Nazis, Churchill laid bare its implications, insisting that it represented "a total and unmitigated defeat." In March 1939 Churchill and his group pressed for a truly national coalition, and, at last, sentiment in the country, recognizing him as the nation's spokesman, began to agitate for his return to office. As long as peace lasted, Chamberlain ignored all such persuasions.

Churchill versus Chamberlain

LEADERSHIP DURING WORLD WAR II

In a sense, the whole of Churchill's previous career had been a preparation for wartime leadership. An intense patriot; a romantic believer in his country's greatness and its historic role in Europe, the empire, and the world; a devotee of action who thrived on challenge and crisis; a student, historian, and veteran of war; a statesman who was master of the arts of politics, despite or because of long political exile; a man of iron constitution, inexhaustible energy, and total concentration, he seemed to have been nursing all his faculties so that when the moment came he could lavish them on the salvation of Britain and the values he believed Britain stood for in the world.

On Sept. 3, 1939, the day Britain declared war on Germany, Chamberlain appointed Churchill to his old post in charge of the Admiralty. The signal went out to the fleet: "Winston is back." On September 11 Churchill received a congratulatory note from Pres. Franklin D. Roosevelt and replied over the signature "Naval Person"; a memorable correspondence had begun. At once Churchill's restless energy began to be felt throughout the administration, as his ministerial colleagues as well as his own department received the first of those pungent minutes that kept the remotest corners of British wartime government aware that their shortcomings were liable to detection and penalty. All his efforts, however, failed to energize the torpid Anglo-French entente during the so-called "phony war," the period of stagnation in the European war before the German seizure of Norway in April 1940. The failure of the Narvik and Trondheim expeditions, dependent as they were on naval support, could not but evoke some memories of the Dardanelles and Gallipoli, so fateful for Churchill's reputation in World War I. This time, however, it was Chamberlain who was blamed, and it was Churchill who endeavoured to defend him.

As prime minister. The German invasion of the Low Countries, on May 10, 1940, came like a hammer blow on top of the Norwegian fiasco. Chamberlain resigned. He wanted Lord Halifax, the foreign secretary, to succeed him, but Halifax wisely declined. It was obvious that

Churchill alone could unite and lead the nation, since the Labour Party, for all its old distrust of Churchill's anti-Socialism, recognized the depth of his commitment to the defeat of Hitler. A coalition government was formed that included all elements save the far left and right. It was headed by a war Cabinet of five, which included at first both Chamberlain and Halifax—a wise but also magnanimous recognition of the numerical strength of Chamberlainite conservatism—and two Labour leaders, Clement Attlee and Arthur Greenwood. The appointment of Ernest Bevin, a tough trade-union leader, as minister of labour guaranteed cooperation on this vital front. Offers were made to Lloyd George, but he declined them. Churchill himself took, in addition to the leadership of the House of Commons, the Ministry of Defence. The pattern thus set was maintained throughout the war despite many changes of personnel. The Cabinet became an agency of swift decision, and the government that it controlled remained representative of all groups and parties. The Prime Minister concentrated on the actual conduct of the war. He delegated freely but also probed and interfered continuously, regarding nothing as too large or too small for his attention. The main function of the chiefs of the armed services became that of containing his great dynamism, as a governor regulates a powerful machine; but, though he prodded and pressed them continuously, he never went against their collective judgment. In all this, Parliament played a vital part. If World War II was strikingly free from the domestic political intrigues of World War I, it was in part because Churchill, while he always dominated Parliament, never neglected it or took it for granted. For him, Parliament was an instrument of public persuasion on which he played like a master and from which he drew strength and comfort.

Churchill and Parliament

On May 13 Churchill faced the House of Commons for the first time as prime minister. He warned members of the hard road ahead—"I have nothing to offer but blood, toil, tears and sweat"—and committed himself and the nation to all-out war until victory was achieved. Behind this simplicity of aim lay an elaborate strategy to which he adhered with remarkable consistency throughout the war. Hitler's Germany was the enemy; nothing should distract the entire British people from the task of effecting its defeat. Anyone who shared this goal, even a Communist, was an acceptable ally. The indispensable ally in this endeavour, whether formally at war or not, was the United States. The cultivation and maintenance of its support was a central principle of Churchill's thought. Yet whether the United States became a belligerent partner or not, the war must be won without a repetition for Britain of the catastrophic bloodlettings of World War I; and Europe at the conflict's end must be reestablished as a viable, self-determining entity, while the Commonwealth should remain as a continuing, if changing, expression of Britain's world role. Provided these essentials were preserved, Churchill, for all his sense of history, was surprisingly willing to sacrifice any national shibboleths—of orthodox economics, of social convention, of military etiquette or tradition—on the altar of victory. Thus, within a couple of weeks of this crusading anti-Socialist's assuming power, Parliament passed legislation placing all "persons, their services and their property at the disposal of the Crown"—granting the government in effect the most sweeping emergency powers in modern British history.

The effort was designed to match the gravity of the hour. After the Allied defeat and the evacuation of the battered British forces from Dunkirk, Churchill warned Parliament that invasion was a real risk to be met with total and confident defiance. Faced with the swift collapse of France, Churchill made repeated personal visits to the French government in an attempt to keep France in the war, culminating in the celebrated offer of Anglo-French union on June 16, 1940. When all this failed, the Battle of Britain began. Here Churchill was in his element, in the firing line—at fighter headquarters, inspecting coast defenses or antiaircraft batteries, visiting scenes of bomb damage or victims of the "blitz," smoking his cigar, giving his V sign, or broadcasting frank reports to the nation, laced with touches of grim Churchillian humour and splashed with Churchillian rhetoric. The nation took him to its heart; he and they were one in "their finest hour."

The Battle of Britain

Other painful and more debatable decisions fell to Churchill. The French fleet was attacked to prevent its surrender intact to Hitler. A heavy commitment was made to the concentrated bombing of Germany. At the height of the invasion threat, a decision was made to reinforce British strength in the eastern Mediterranean. Forces were also sent to Greece, a costly sacrifice; the evacuation of Crete looked like another Gallipoli, and Churchill came under heavy fire in Parliament.

In these hard days the exchange of U.S. overage destroyers for British Caribbean bases and the response, by way of lend-lease, to Churchill's boast "Give us the tools and we'll finish the job" were especially heartening to one who believed in a "mixing-up" of the English-speaking democracies. The unspoken alliance was further cemented in August 1941 by the dramatic meeting between Churchill and Roosevelt in Placentia Bay, Newfoundland, which produced the Atlantic Charter, a statement of common principles between the United States and Britain.

Formation of the "grand alliance." When Hitler launched his sudden attack on the Soviet Union, Churchill's response was swift and unequivocal. In a broadcast on June 22, 1941, while refusing to "unsay" any of his earlier criticisms of Communism, he insisted that "the Russian danger . . . is our danger" and pledged aid to the Russian people. Henceforth, it was his policy to construct a "grand alliance" incorporating the Soviet Union and the United States. But it took until May 1942 to negotiate a 20-year Anglo-Soviet pact of mutual assistance.

The Japanese attack on Pearl Harbor (Dec. 7, 1941) altered, in Churchill's eyes, the whole prospect of the war. He went at once to Washington, D.C., and, with Roosevelt, hammered out a set of Anglo-American accords: the pooling of both countries' military and economic resources under combined boards and a combined chiefs of staff; the establishment of unity of command in all theatres of war; and agreement on the basic strategy that the defeat of Germany should have priority over the defeat of Japan. The grand alliance had now come into being. Churchill could claim to be its principal architect. Safeguarding it was the primary concern of his next three and a half years.

The accord with Roosevelt

In protecting the alliance, the respect and affection between him and Roosevelt were of crucial importance. They alone enabled Churchill, in the face of relentless pressure from Stalin and ardent advocacy by the U.S. chiefs of staff, to secure the rejection of the "second front" in 1942, a project he regarded as premature and costly. In August 1942 Churchill himself flew to Moscow to advise Stalin of the decision and to bear the brunt of his displeasure. At home, too, he came under fire in 1942: first in January after the reverses in Malaya and the Far East and later in June when Tobruk in North Africa fell to the Germans, but on neither occasion did his critics muster serious support in Parliament. The year 1942 saw some reconstruction of the Cabinet in a "leftward" direction, which was reflected in the adoption in 1943 of Lord Beveridge's plan for comprehensive social insurance, endorsed by Churchill as a logical extension of the Liberal reforms of 1911.

Military successes and political problems. The Allied landings in North Africa necessitated a fresh meeting between Churchill and Roosevelt, this time in Casablanca in January 1943. There Churchill argued for an early, full-scale attack on "the under-belly of the Axis" but won only a grudging acquiescence from the Americans. There too was evolved the "unconditional surrender" formula of debatable wisdom. Churchill paid the price for his intensive travel (including Tripoli, Turkey, and Algeria) by an attack of pneumonia, for which, however, he allowed only the briefest of respites. In May he was in Washington again, arguing against persistent American aversion to his "under-belly" strategy; in August he was at Quebec, working out the plans for Operation Overlord, the cross-Channel assault. When he learned that the Americans were planning a large-scale invasion of Burma in 1944, his fears that their joint resources would not be adequate

Operation Overlord

for a successful invasion of Normandy were revived. In November 1943 at Cairo he urged on Roosevelt priority for further Mediterranean offensives, but at Tehrān in the first "Big Three" meeting, he failed to retain Roosevelt's adherence to a completely united Anglo-American front. Roosevelt, though he consulted in private with Stalin, refused to see Churchill alone; for all their friendship there was also an element of rivalry between the two Western leaders that Stalin skillfully exploited. On the issue of Allied offensive drives into southern Europe, Churchill was outvoted. Throughout the meetings Churchill had been unwell, and on his way home he came down again with pneumonia. Though recovery was rapid, it was mid-January 1944 before convalescence was complete. By May he was proposing to watch the D-Day assaults from a battle cruiser; only the King's personal plea dissuaded him.

Insistence on military success did not, for Churchill, mean indifference to its political implications. After the Quebec conference in September 1944, he flew to Moscow to try to conciliate the Russians and the Poles and to get an agreed division of spheres of influence in the Balkans that would protect as much of them as possible from Communism. In Greece he used British forces to thwart a Communist takeover and at Christmas flew to Athens to effect a settlement. Much of what passed at the Yalta Conference in February 1945, including the Far East settlement, concerned only Roosevelt and Stalin, and Churchill did not interfere. He fought to save the Poles but saw clearly enough that there was no way to force the Soviets to keep their promises. Realizing this, he urged the United States to allow the Allied forces to thrust as far into eastern Europe as possible before the Russian armies should fill the vacuum left by German power, but he could not win over Roosevelt, Vice Pres. Harry S. Truman, or their generals to his views. He went to Potsdam in July in a worried mood. But in the final decisions of the conference he had no part; halfway through, when news came of his government's defeat in parliamentary elections, he had to return to England and tender his resignation.

Electoral defeat. Already in 1944, with victory in prospect, party politics had revived, and by May 1945 all parties in the wartime coalition wanted an early election. But whereas Churchill wanted the coalition to continue at least until Japan was defeated, Labour wished to resume its independence. Churchill as the popular architect of victory seemed unbeatable, but as an election campaigner he proved to be his own worst enemy, indulging, seemingly at Beaverbrook's urging, in extravagant prophecies of the appalling consequences of a Labour victory and identifying himself wholly with the Conservative cause. His campaign tours were a triumphal progress, but it was the war leader, not the party leader, whom the crowds cheered. Labour's careful but sweeping program of economic and social reform was a better match for the nation's mood than Churchill's flamboyance. Though personally victorious at his Essex constituency of Woodford, Churchill saw his party reduced to 213 seats in a Parliament of 640.

POSTWAR POLITICAL CAREER

As opposition leader and world statesman. The shock of rejection by the nation fell heavily on Churchill. Indeed, though he accepted the role of leader of the parliamentary opposition, he was never wholly at home in it. The economic and social questions that dominated domestic politics were not at the centre of his interests. Nor, with his imperial vision, could he approve of what he called Labour's policy of "scuttle," as evidenced in the granting of independence to India and Burma (though he did not vote against the necessary legislation). But in foreign policy a broad identity of view persisted between the front benches, and this was the area to which Churchill primarily devoted himself. On March 5, 1946, at Fulton, Mo., he enunciated, in the presence of President Truman, the two central themes of his postwar view of the world: the need for Britain and the United States to unite as guardians of the peace against the menace of Soviet Communism, which had brought down an "iron curtain" across the face of Europe; and with equal fervour he emerged as an advocate of European union. At Zürich, on Sept. 19, 1946, he urged the formation of "a council of Europe" and himself attended the first assembly of the council at Strasbourg in 1949. Meanwhile, he busied himself with his great history, *The Second World War*, six volumes (1948–53).

The "iron curtain" speech

The general election of February 1950 afforded Churchill an opportunity to seek again a personal mandate. He abstained from the extravagances of 1945 and campaigned with his party rather than above it.

The electoral onslaught shook Labour but left them still in office. It took what Churchill called "one more heave" to defeat them in a second election, in October 1951. Churchill again took a vigorous lead in the campaign. He pressed the government particularly hard on its handling of the crisis caused by Iran's nationalization of British oil companies and in return had to withstand charges of warmongering. The Conservatives were returned with a narrow majority of 26, and Churchill became prime minister for the second time. He formed a government in which the more liberal Conservatives predominated, though the Liberal Party itself declined Churchill's suggestion of office. A prominent figure in the government was R.A. Butler, the progressive-minded chancellor of the Exchequer. Anthony Eden was foreign secretary. Some notable Churchillians were included, among them Lord Cherwell, who, as paymaster general, was principal scientific adviser with special responsibilities for atomic research and development.

As prime minister again. The domestic labours and battles of his administration were far from Churchill's main concerns. Derationing, decontrolling, rehousing, safeguarding the precarious balance of payments—these were relatively noncontroversial policies; only the return of nationalized steel and road transport to private hands aroused excitement. Critics sometimes complained of a lack of prime ministerial direction in these areas and, indeed, of a certain slackness in the reins of government. Undoubtedly Churchill was getting older and reserving more and more of his energies for what he regarded as the supreme issues, peace and war. He was convinced that Labour had allowed the transatlantic relationship to sag, and one of his first acts was to visit Washington (and also Ottawa) in January 1952 to repair the damage he felt had been done. The visit helped to check U.S. fears that the British would desert the Korean War, harmonized attitudes toward German rearmament and, distasteful though it was to Churchill, resulted in the acceptance of a U.S. naval commander in chief of the eastern Atlantic. It did not produce that sharing of secrets of atom bomb manufacture that Churchill felt had unfairly lapsed after the war. To the disappointment of many, Churchill's advocacy of European union did not result in active British participation; his government confined itself to endorsement from the sidelines, though in 1954, faced with the collapse of the European Defense Community, Churchill and Eden came forward with a pledge to maintain British troops on the Continent for as long as necessary.

Advocacy of European unity

The year 1953 was in many respects a gratifying one for Churchill. It brought the coronation of Queen Elizabeth II, which drew out all his love of the historic and symbolic. He personally received two notable distinctions, the Order of the Garter and the Nobel Prize for Literature. However, his hopes for a revitalized "special relationship" with Pres. Dwight D. Eisenhower during his tenure in the White House, beginning in 1953, were largely frustrated. A sudden stroke in June, which caused partial paralysis, obliged Churchill to cancel a planned Bermuda meeting at which he hoped to secure Eisenhower's agreement to summit talks with the Russians. By October, Churchill had made a remarkable recovery and the meeting was held in December. But it did not yield results commensurate with Churchill's hopes. The two leaders, for all their amity, were not the men they once were; their subordinates, John Foster Dulles and Anthony Eden, were antipathetic; and, above all, the role and status of each country had changed. In relation to the Far East in particular there was a persistent failure to see eye to eye. Though Churchill and Eden visited Washington, D.C., in June 1954 in hopes of securing U.S. acceptance of the Geneva Accords designed to bring an end to the war in Indochina, their success was limited. Over Egypt, however, Churchill's conversion to

an agreement permitting a phased withdrawal of British troops from the Suez base won Eisenhower's endorsement and encouraged hopes, illusory as it subsequently appeared, of good Anglo-American cooperation in this area. In 1955, "arming to parley," Churchill authorized the manufacture of a British hydrogen bomb while still striving for a summit conference. Age, however, robbed him of this last triumph. His powers were too visibly failing. His 80th birthday, on Nov. 30, 1954, had been the occasion of a unique all-party ceremony of tribute and affection in Westminster Hall. But the tribute implied a pervasive assumption that he would soon retire. On April 5, 1955, his resignation took place, only a few weeks before his chosen successor, Sir Anthony Eden, announced plans for a four-power conference at Geneva.

Retirement and death. Although Churchill laid down the burdens of office amid the plaudits of the nation and the world, he remained in the House of Commons (declining a peerage) to become "father of the house" and even, in 1959, to fight and win yet another election. He also published another major work, *A History of the English-Speaking Peoples,* four volumes (1956–58). But his health declined, and his public appearances became rare. On April 9, 1963, he was accorded the unique distinction of having an honorary U.S. citizenship conferred on him by an act of Congress. His death at his London home on Jan. 24, 1965, was followed by a state funeral at which almost the whole world paid tribute. He was buried in the family grave in Bladon churchyard, Oxfordshire.

Assessment. In any age and time a man of Churchill's force and talents would have left his mark on events and society. A gifted journalist, a biographer and historian of classic proportions, an amateur painter of talent, an orator of rare power, a soldier of courage and distinction, Churchill, by any standards, was a man of rare versatility. But it was as a public figure that he excelled. His experience of office was second only to Gladstone's, and his gifts as a parliamentarian hardly less, but it was as a wartime leader that he left his indelible imprint on the history of Britain and on the world. In this capacity, at the peak of his powers, he united in a harmonious whole his liberal convictions about social reform, his deep conservative devotion to the legacy of his nation's history, his unshakable resistance to tyranny from the right or from the left, and his capacity to look beyond Britain to the larger Atlantic community and the ultimate unity of Europe. A romantic, he was also a realist, with an exceptional sensitivity to tactical considerations at the same time as he unswervingly adhered to his strategical objectives. A fervent patriot, he was also a citizen of the world. An indomitable fighter, he was a generous victor. Even in the transition from war to peace, a phase in which other leaders have often stumbled, he revealed, at an advanced age, a capacity to learn and to adjust that was in many respects superior to that of his younger colleagues.

MAJOR WORKS

HISTORY: *The Story of the Malakand Field Force* (1898); *The River War* (1899); *The World Crisis* (1923–29); *The Unknown War: The Eastern Front* (1931); *The Second World War* (1948–53); *A History of the English-Speaking Peoples* (1956–58).

BIOGRAPHY AND AUTOBIOGRAPHY: *Lord Randolph Churchill* (1906); *My African Journey* (1908); *My Early Life* (1930); *Marlborough: His Life and Times* (1933–38).

SPEECHES: *Into Battle* (1941); *The Unrelenting Struggle* (1942); *The End of the Beginning* (1943); *Onwards to Victory* (1944); *The Dawn of Liberation* (1945); *Victory* (1946); *Secret Session Speeches* (1946); *The Sinews of Peace* (1948); *Europe Unite* (1950); *In the Balance* (1951); *Stemming the Tide* (1953); *The Unwritten Alliance* (1961). The speeches have been collected in *Winston S. Churchill: His Complete Speeches, 1897–1963,* 8 vol. (1974).

OTHER WORKS: *Savrola* (1900); *Thoughts and Adventures* (1932); *Painting As a Pastime* (1948).

BIBLIOGRAPHY. The official biography, *Winston S. Churchill* (1966–), was begun by Churchill's son, RANDOLPH S. CHURCHILL, and continued by MARTIN GILBERT, each volume covering a successive span of years and supported by companion volumes of documents. Churchill's own writings are an indispensable autobiographical source; see *While England Slept: A Survey of World Affairs, 1932–1938,* with preface and notes by RANDOLPH S. CHURCHILL (1938, reprinted 1971; U.K. title, *Arms and the Covenant: Speeches,* 1938, reissued 1975). VIOLET BONHAM CARTER, *Winston Churchill: An Intimate Portrait* (U.K. title, *Winston Churchill As I Knew Him,* 1965), is a vivid memoir. LORD CHARLES MORAN, *Churchill: The Struggle for Survival, 1940–1965* (1966, reissued 1976), written by his physician, gives intimate glimpses of his late years. See also HENRY PELLING, *Winston Churchill* (1974, reissued 1977), a comprehensive biography; JOSEPH P. LASH, *Roosevelt and Churchill, 1939–1941: The Partnership That Saved the West* (1976), a study that illustrates the importance of Churchill's strong personality and the force of his ideas; FRANÇOIS KERSAUDY, *Churchill and de Gaulle* (1981, reissued 1983); and WARREN F. KIMBALL (ed.), *Churchill and Roosevelt: The Complete Correspondence,* 3 vol. (1984), both studies of their wartime relationships; and JOHN COLVILLE, *The Fringes of Power: Downing Street Diaries, 1939–1955* (1985), a portrait of Churchill by the civil servant who was his private secretary during most of World War II and again in 1951–55.

(H.G.N.)

Circulation and Circulatory Systems

Within any living organism, the process of circulation involves all of the fluids of the body and permits a continuous integration among various tissues. Important in this process is the intake of metabolic materials, the conveyance of these materials throughout the organism, and the return of harmful by-products to the environment.

Invertebrate animals have a great variety of liquids, cells, and modes of circulation, though many invertebrates have what is called an open system, in which fluid passes more or less freely throughout the tissues or defined areas of tissue. All vertebrates, however, have a closed system—that is, their circulatory system transmits fluid through an intricate network of vessels. This system contains two fluids, blood and lymph, and functions by means of two interacting modes of circulation, the cardiovascular system and the lymphatic system; both the fluid components and the vessels through which they flow reach their greatest elaboration and specialization in the mammalian systems and, particularly, in the human body.

For this reason the human cardiovascular system is discussed in a separate section of this article and is preceded by a general survey of the circulatory systems of all other animals, from the single-celled to the vertebrate. Finally, the last section of the article is concerned with the diseases and disorders of the human cardiovascular system and includes a discussion of various surgical treatments of the heart.

A full treatment of human blood and its various components can be found in the article BLOOD. A discussion of how the systems of circulation, respiration, and metabolism work together within an animal organism is found in the article RESPIRATION AND RESPIRATORY SYSTEMS. (Ed.)

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 421 and 422, and the *Index.*

This article is divided into the following sections:

Main features of circulatory systems

GENERAL FEATURES OF CIRCULATION

All living organisms take in molecules from their environments, use them to support the metabolism of their own substance, and release by-products back into the environment. The internal environment differs more or less greatly from the external environment, depending on the species. It is normally maintained at constant conditions by the organism so that it is subject to relatively minor fluctuations. In individual cells, either as independent organisms or as parts of the tissues of multicellular animals, molecules are taken in either by their direct diffusion through the cell wall or by the formation by the surface membrane of vacuoles that carry some of the environmental fluid containing dissolved molecules. Within the cell, cyclosis (streaming of the fluid cytoplasm) distributes the metabolic products.

Molecules are normally conveyed between cells and throughout the body of multicellular organisms in a circulatory fluid, called blood, through special channels, called blood vessels, by some form of pump, which, if restricted in position, is usually called a heart. In vertebrates blood and lymph (the circulating fluids) have an essential role in maintaining homeostasis (the constancy of the internal environment) by distributing substances to parts of the body when required and by removing others from areas in which their accumulation would be harmful.

The animal kingdom can be divided into two subkingdoms—Protozoa, which contains the unicellular animals; and Metazoa, which contains all the multicellular animals. The Metazoa may be further divided into the Parazoa, which contains the Porifera (sponges), which lack defined tissues and have no organs; and Eumetazoa, which contains all of the remaining multicellular (metazoan) animals.

The Eumetazoa

One eumetazoan phylum, Cnidaria (Coelenterata)—which includes sea anemones, jellyfish, and corals—has a diploblastic level of organization (*i.e.,* its members have two layers of cells). The outer layer, called the ectoderm, and the inner layer, called the endoderm, are separated by an amorphous, acellular layer called the mesoglea; for these animals, bathing both cellular surfaces with environmental fluid is sufficient to supply their metabolic needs. All other major eumetazoan phyla are triploblastic (*i.e.,* their members have three layers of cells), with the third cellular layer, called the mesoderm, developing between the endoderm and ectoderm. At its simplest, the mesoderm provides a network of packing cells around the animal's organs; this is probably best exhibited in the phylum Platyhelminthes (flatworms).

Nematoda, Rotifera, and a number of other smaller eumetazoan classes and phyla have a fluid-filled cavity, called the pseudocoelom, that arises from an embryonic cavity and contains the internal organs free within it. All other eumetazoans have a body cavity, the coelom, which originates as a cavity in the embryonic mesoderm. Mesoderm lines the coelom and forms the peritoneum, which also surrounds and supports the internal organs. While this increase in complexity allows for increase in animal size, it has certain problems. As the distances from metabolizing cells to the source of metabolites (molecules to be metabolized) increases, a means of distribution around the body is necessary for all but the smallest coelomates.

Many invertebrate animals are aquatic and the problem of supplying fluid is not critical. For terrestrial organisms, however, the fluid reaching the tissues comes from water that has been drunk, absorbed in the alimentary canal, and passed to the bloodstream. Fluid may leave the blood, usually with food and other organic molecules in solution, and pass to the tissues, from which it returns in the form of lymph. Especially in the vertebrates, lymph passes through special pathways, called lymphatic channels, to provide the lymphatic circulation.

In many invertebrates, however, the circulating fluid is not confined to distinct vessels, and it more or less freely bathes the organs directly. The functions of both circulating and tissue fluid are thus combined in the fluid, often known as hemolymph. The possession of a blood supply and coelom, however, does not exclude the circulation of environmental water through the body. Members of the phylum Echinodermata (starfishes and sea urchins, for example) have a complex water vascular system used mainly for locomotion.

Circulatory systems

An internal circulatory system transports essential gases and nutrients around the body of an organism, removes unwanted products of metabolism from the tissues, and carries these products to specialized excretory organs, if present. Although a few invertebrate animals circulate external water through their bodies for respiration, and, in the case of cnidarians, nutrition, most species circulate an internal fluid, called blood.

There may also be external circulation that sets up currents in the environmental fluid to carry it over respiratory surfaces and, especially in the case of sedentary animals, to carry particulate food that is strained out and passed to the alimentary canal. Additionally, the circulatory system may assist the organism in movement; for example, protoplasmic streaming in amoeboid protozoans circulates nutrients and provides pseudopodal locomotion. The hydrostatic pressure built up in the circulatory systems of many invertebrates is used for a range of whole-body and individual-organ movement.

BODY FLUIDS

The fluid compartments of animals consist of intracellular and extracellular components. The intracellular component includes the body cells and, where present, the blood cells, while the extracellular component includes the tissue fluid, coelomic fluid, and blood plasma. In all cases the major constituent is water derived from the environment. The composition of the fluid varies markedly depending on its source and is regulated more or less precisely by homeostasis.

Blood and coelomic fluid are often physically separated by the blood-vessel walls; where a hemocoel (a blood-containing body cavity) exists, however, blood rather than coelomic fluid occupies the cavity. The composition of blood may vary from what is little more than the environmental water containing small amounts of dissolved nutrients and gases to the highly complex tissue containing many cells of different types found in mammals.

Lymph essentially consists of blood plasma that has left the blood vessels and has passed through the tissues. It is generally considered to have a separate identity when it is returned to the bloodstream through a series of vessels independent of the blood vessels and the coelomic space. Coelomic fluid itself may circulate in the body cavity. In most cases this circulation has an apparently random nature, mainly because of movements of the body and organs. In some phyla, however, the coelomic fluid has a more important role in internal distribution and is circulated by ciliary tracts.

FLUID COMPARTMENTS

Blood is circulated through vessels of the blood vascular system. Blood is moved through this system by some form of pump. The simplest pump, or heart, may be no more than a vessel along which a wave of contraction passes to propel the blood. This simple, tubular heart is adequate where low blood pressure and relatively slow circulation rates are sufficient to supply the animal's metabolic requirements, but it is inadequate in larger, more active, and more demanding species. In the latter animals, the heart is usually a specialized, chambered, muscular pump that receives blood under low pressure and returns it under higher pressure to the circulation. Where the flow of blood is in one direction, as is normally the case, valves in the form of flaps of tissue prevent backflow.

Heartbeat

A characteristic feature of hearts is that they pulsate throughout life and any prolonged cessation of heartbeat is fatal. Contractions of the heart muscle may be initiated in one of two ways. In the first, the heart muscle may have an intrinsic contractile property that is independent of the nervous system. This myogenic contraction is found in all vertebrates and some invertebrates. In the second, the heart is stimulated by nerve impulses from outside the heart muscle. The hearts of other invertebrates exhibit this neurogenic contraction.

The cardiac cycle

Chambered hearts, as found in vertebrates and some larger invertebrates, consist of a series of interconnected muscular compartments separated by valves. The first chamber, the auricle, acts as a reservoir to receive the blood that then passes to the second and main pumping chamber, the ventricle. Expansion of a chamber is known as diastole and contraction as systole. As one chamber undergoes systole the other undergoes diastole, thus forcing the blood forward. The series of events during which blood is passed through the heart is known as the cardiac cycle.

Contraction of the ventricle forces the blood into the vessels under pressure, known as the blood pressure. As contraction continues in the ventricle, the rising pressure is sufficient to open the valves that had been closed because of attempted reverse blood flow during the previous cycle. At this point the ventricular pressure transmits a high-speed wave, the pulse, through the blood of the arterial system. The volume of blood pumped at each contraction of the ventricle is known as the stroke volume, and the output is usually dependent on the animal's activity.

Blood vessels

After leaving the heart, the blood passes through a series of branching vessels of steadily decreasing diameter. The smallest branches, only a few micrometres (there are about 25,000 micrometres in one inch) in diameter, are the capillaries, which have thin walls through which the fluid part of the blood may pass to bathe the tissue cells. The capillaries also pick up metabolic end products and carry them into larger collecting vessels that eventually return the blood to the heart. In vertebrates there are structural differences between the muscularly walled arteries, which carry the blood under high pressure from the heart, and the thinner walled veins, which return it at much reduced pressure. Although such structural differences are less apparent in invertebrates, the terms artery and vein are used for vessels that carry blood from and to the heart, respectively.

The closed circulatory system found in vertebrates is not universal; a number of invertebrate phyla have an "open" system. In the latter animals, the blood leaving the heart passes into a series of open spaces, called sinuses, where it bathes internal organs directly. Such a body cavity is called a hemocoel, a term that reflects the amalgamation of the blood system and the coelom.

Invertebrate circulatory systems

BASIC PHYSICOCHEMICAL CONSIDERATIONS

Optimal metabolism

To maintain optimum metabolism, all living cells require a suitable environment, which must be maintained within relatively narrow limits. An appropriate gas phase (*i.e.*, suitable levels of oxygen and other gases), an adequate and suitable nutrient supply, and a means of disposal of unwanted products are all essential.

Direct diffusion through the body surface supplies the necessary gases and nutrients for small organisms, but even some single-celled protozoa have a rudimentary circulatory system. Cyclosis in many ciliates carries food vacuoles—which form at the forward end of the gullet (cytopharynx)—on a more or less fixed route around the cell, while digestion occurs to a fixed point of discharge.

For most animal cells, the supply of oxygen is largely independent of the animal and therefore is a limiting factor in its metabolism and ultimately in its structure and distribution. The nutrient supply to the tissues, however, is controlled by the animal itself, and, because both major catabolic end products of metabolism—ammonia (NH_3) and carbon dioxide (CO_2)—are more soluble than oxygen (O_2) in water and the aqueous phase of the body fluids, they tend not to limit metabolic rates. The diffusion rate of CO_2 is less than that of O_2, but its solubility is 30 times that of oxygen. This means that the amount of CO_2 diffusing is 26 times as high as for oxygen at the same temperature and pressure.

The oxygen available to a cell depends on the concentration of oxygen in the external environment and the efficiency with which it is transported to the tissues. Dry air at atmospheric pressure contains about 21 percent oxygen, the percentage of which decreases with increasing altitude. Well-aerated water has the same percentage of oxygen as the surrounding air; however, the amount of dissolved oxygen is governed by temperature and the presence of other solutes. For example, seawater contains 20 percent less oxygen than fresh water under the same conditions.

Rate of diffusion

The rate of diffusion depends on the shape and size of the diffusing molecule, the medium through which it diffuses, the concentration gradient, and the temperature. These physicochemical constraints imposed by gaseous diffusion have a relationship with animal respiration. Investigations have suggested that a spherical organism larger than 0.5 millimetre (0.02 inch) radius would not obtain enough oxygen for the given metabolic rate, and so a supplementary transport mechanism would be required. Many invertebrates are small, with direct diffusion distances of less than 0.5 millimetre. Considerably larger species, however, still survive without an internal circulatory system.

ANIMALS WITHOUT INDEPENDENT VASCULAR SYSTEMS

A sphere represents the smallest possible ratio of surface area to volume; modifications in architecture, reduction of metabolic rate, or both may be exploited to allow size increase. Sponges (Figure 1A) overcome the problem of oxygen supply and increase the chance of food capture by passing water through their many pores using ciliary action. The level of organization of sponges is that of a coordinated aggregation of largely independent cells with poorly defined tissues and no organ systems. The whole animal has a relatively massive surface area for gaseous exchange, and all cells are in direct contact with the passing water current.

Among the eumetazoan (multicellular) animals the cnidarians (sea anemones, corals, and jellyfish) are diploblastic, the inner endoderm and outer ectoderm being separated by an acellular mesoglea. Sea anemones and corals may also grow to considerable size and exhibit complex external structure that, again, has the effect of increasing surface area. Their fundamentally simple structure—with a gastrovascular cavity continuous with the external environmental water—allows both the endodermal and ectodermal cells of the body wall access to aerated water, permitting direct diffusion (Figure 1B).

Circulation in jellyfish

This arrangement is found in a number of other invertebrates, such as Ctenophora (comb jellies), and is exploited further by jellyfish, which also show a rudimentary internal circulatory system. The thick, largely acellular, gelatinous bell of a large jellyfish may attain a diameter of 40 centimetres (16 inches) or more. The gastrovascular cavity is modified to form a series of water-filled canals that ramify through the bell and extend from the central gastric pouches to a circular canal that follows the periphery of the umbrella. Ciliary activity within the canals slowly passes food particles and water, taken in through the mouth, from the gastric pouches (where digestion is initiated) to other parts of the body. Ciliary activity is a relatively inefficient means of translocating fluids, and it may take up to half an hour to complete a circulatory cycle through even a small species. To compensate for the inefficiency of the circulation, the metabolic rate of the jellyfish is low, and organic matter makes up only a small proportion of the total body constituents. The central mass of the umbrella may be a considerable distance from either the exumbrella surface or the canal system, and, while it contains some wandering amoeboid cells, its largely acellular nature means that its metabolic requirements are small.

VASCULAR SYSTEMS

While ciliary respiratory currents are sufficient to supply the requirements of animals with simple epithelial tissues and low metabolic rates, most species whose bodies contain a number of organ systems require a more efficient circulatory system. Many invertebrates and all vertebrates have a closed vascular system in which the circulatory fluid is totally confined within a series of vessels consisting of arteries, veins, and fine linking capillaries. Insects, most crustaceans, and many mollusks, however, have an open system in which the circulating fluid passes somewhat freely among the tissues before being collected and recirculated.

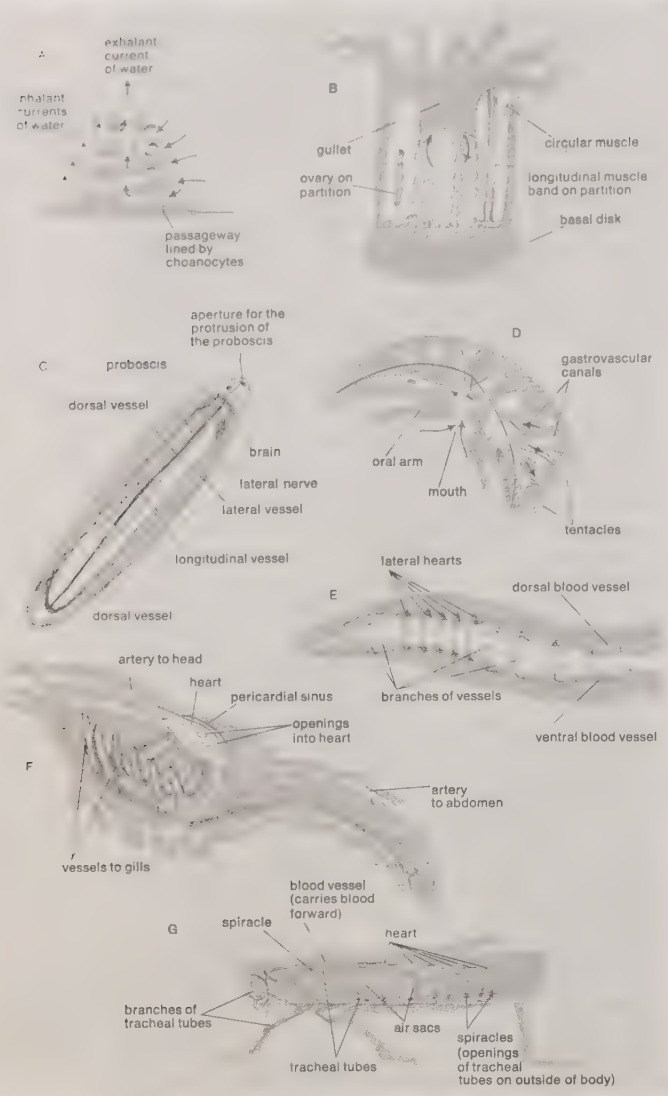

Figure 1: Vertical section through (A) sponge and (B) sea anemone, with water circulation indicated by arrows; (C) circulation in nemertean worm; (D) internal arrangement of ciliated endodermal canals in jellyfish; arrows show the direction of water currents; (E) circulation in earthworm; (F) circulation in decapod crustacean; (G) circulation in insect (grasshopper).

Haswell, *Textbook of Zoology*, St. Martin's Press, Inc., Macmillan & Co., Ltd., (E,G) Biological Sciences Curriculum Study, *Biological Science: An Inquiry Into Life*, second edition, 1968, Harcourt Brace Jovanovich

The distinction between open and closed circulatory systems may not be as great as was once thought; some crustaceans have vessels with dimensions similar to those of vertebrate capillaries before opening into tissue sinuses. The circulatory fluid in open systems is strictly hemolymph, but the term "blood" is commonly used to denote the transporting medium in both open and closed systems. Compared with closed systems, open circulatory systems generally work at lower pressures, and the rate of fluid return to the heart is slower. Blood distribution to individual organs is not regulated easily, and the open system is not as well-adapted for rapid response to change.

Blood. The primary body cavity (coelom) of triploblastic multicellular organisms arises from the central mesoderm, which emerges from between the endoderm and ectoderm during embryonic development. The fluid of the coelom containing free mesodermal cells constitutes the blood and lymph. The composition of blood varies between different organisms and within one organism at different stages during its circulation. Essentially, however, the blood consists of an aqueous plasma containing sodium, potassium, calcium, magnesium, chloride, and sulfate ions; some trace elements; a number of amino acids; and possibly a protein known as a respiratory pigment. If present in invertebrates, the respiratory pigments are normally dissolved in the plasma and are not enclosed in blood cells. The constancy of the ionic constituents of blood and their similarity to seawater have been used by some scientists as evidence of a common origin for life in the sea.

Composition of blood

An animal's ability to control its gross blood concentration (*i.e.*, the overall ionic concentration of the blood) largely governs its ability to tolerate environmental changes. In many marine invertebrates, such as echinoderms and some mollusks, the osmotic and ionic characteristics of the blood closely resemble those of seawater. Other aquatic, and all terrestrial, organisms, however, maintain blood concentrations that differ to some extent from their environments and thus have a greater potential range of habitats. In addition to maintaining the overall stability of the internal environment, blood has a range of other functions. It is the major means of transport of nutrients, metabolites, excretory products, hormones, and gases, and it may provide the mechanical force for such diverse processes as hatching and molting in arthropods and burrowing in bivalve mollusks.

Hemocytes

Invertebrate blood may contain a number of cells (hemocytes) arising from the embryonic mesoderm. Many different types of hemocytes have been described in different species, but they have been studied most extensively in insects, in which four major types and functions have been suggested: (1) phagocytic cells that ingest foreign particles and parasites and in this way may confer some nonspecific immunity to the insect; (2) flattened hemocytes that adhere to the surface of the invader and remove its supply of oxygen, resulting in its death; metazoan parasites that are too large to be engulfed by the phagocytic cells may be encapsulated by these cells instead; (3) hemocytes that assist in the formation of connective tissue and the secretion of mucopolysaccharides during the formation of basement membranes; they may be involved in other aspects of intermediate metabolism as well; and (4) hemocytes that are concerned with wound healing; the plasma of many insects does not coagulate, and either pseudopodia or secreted particles from hemocytes (cystocytes) trap other such cells to close the lesion until the surface of the skin regenerates.

While the solubility of oxygen in blood plasma is adequate to supply the tissues of some relatively sedentary invertebrates, more active animals with increased oxygen demands require an additional oxygen carrier. The oxygen carriers in blood take the form of metal-containing protein molecules that frequently are coloured and thus commonly known as respiratory pigments. The most widely distributed respiratory pigments are the red hemoglobins, which have been reported in all classes of vertebrates, in most invertebrate phyla, and even in some plants. Hemoglobins consist of a variable number of subunits, each containing an iron–porphyrin group attached to a protein. The distribution of hemoglobins in just a few members of a phylum and in many different phyla argues that the hemoglobin type of molecule must have evolved many times with similar iron–porphyrin groups and different proteins.

The green chlorocruorins are also iron–porphyrin pigments and are found in the blood of a number of families of marine polychaete worms. There is a close resemblance between chlorocruorin and hemoglobin molecules, and a number of species of a genus, such as those of *Serpula*, contain both, while some closely related species exhibit an almost arbitrary distribution. For example, *Spirorbis borealis* has chlorocruorin, *S. corrugatus* has hemoglobin, and *S. militaris* has neither.

The third iron-containing pigments, the hemerythrins, are violet. They differ structurally from both hemoglobin and chlorocruorin in having no porphyrin groups and containing three times as much iron, which is attached directly to the protein. Hemerythrins are restricted to a small number of animals, including some polychaete and sipunculid worms, the brachiopod *Lingula*, and some priapulids.

Hemocyanins

Hemocyanins are copper-containing respiratory pigments found in many mollusks (some bivalves, many gastropods,

and cephalopods) and arthropods (many crustaceans, some arachnids, and the horseshoe crab, *Limulus*). They are colourless when deoxygenated but turn blue on oxygenation. The copper is bound directly to the protein, and oxygen combines reversibly in the proportion of one oxygen molecule to two copper atoms.

The presence of a respiratory pigment greatly increases the oxygen-carrying capacity of blood; invertebrate blood may contain up to 10 percent oxygen with the pigment, compared with about 0.3 percent in the absence of the pigment. All respiratory pigments become almost completely saturated with oxygen even at oxygen levels, or pressures, below those normally found in air or water. The oxygen pressures at which the various pigments become saturated depend on their individual chemical characteristics and on such conditions as temperature, pH, and the presence of carbon dioxide.

In addition to their direct transport role, respiratory pigments may temporarily store oxygen for use during periods of respiratory suspension or decreased oxygen availability (hypoxia). They may also act as buffers to prevent large blood pH fluctuations, and they may have an osmotic function that helps to reduce fluid loss from aquatic organisms whose internal hydrostatic pressure tends to force water out of the body.

Hearts. All systems involving the consistent movement of circulating fluid require at least one repeating pump and, if flow is to be in one direction, usually some arrangement of valves to prevent backflow. The simplest form of animal circulatory pump consists of a blood vessel down which passes a wave of muscular contraction, called peristalsis, that forces the enclosed blood in the direction of contraction. Valves may or may not be present. This type of heart is widely found among invertebrates, and there may be many pulsating vessels in a single individual.

In the earthworm, the main dorsal (aligned along the back) vessel contracts from posterior to anterior 15 to 20 times per minute, pumping blood toward the head. At the same time, the five paired segmental lateral (side) vessels, which branch from the dorsal vessel and link it to the ventral (aligned along the bottom) vessel, pulsate with their own independent rhythms. Although unusual, it is possible for a peristaltic heart to reverse direction. After a series of contractions in one direction, the hearts of tunicates (sea squirts) gradually slow down and eventually stop. After a pause the heart starts again, with reverse contractions pumping the blood in the opposite direction.

An elaboration of the simple peristaltic heart is found in the tubular heart of most arthropods, in which part of the dorsal vessel is expanded to form one or more linearly arranged chambers with muscular walls. The walls are perforated by pairs of lateral openings (ostia) that allow blood to flow into the heart from a large surrounding sinus, the pericardium. The heart may be suspended by alary muscles, contraction of which expands the heart and increases blood flow into it. The direction of flow is controlled by valves arranged in front of the in-current ostia.

Chambered hearts with valves and relatively thick muscular walls are less commonly found in invertebrates but do occur in some mollusks, especially cephalopods (octopus and squid). Blood from the gills enters one to four auricles (depending on the species) and is passed back to the tissues by contraction of the ventricle. The direction of flow is controlled by valves between the chambers. The filling and emptying of the heart are controlled by regular rhythmical contractions of the muscular wall.

Chambered hearts

In addition to the main systemic heart, many species have accessory booster hearts at critical points in the circulatory system. Cephalopods have special muscular dilations, the branchial hearts, that pump blood through the capillaries, and insects may have additional ampullar hearts at the points of attachment of many of their appendages.

The control of heart rhythm may be either myogenic (originating within the heart muscle itself) or neurogenic (originating in nerve ganglia). The hearts of the invertebrate mollusks, like those of vertebrates, are myogenic. They are sensitive to pressure and fail to give maximum beats unless distended; the beats become stronger and more frequent with increasing blood pressure. Although under experimental conditions acetylcholine (a substance that transmits nerve impulses across a synapse) inhibits molluscan heartbeat, indicating some stimulation of the heart muscle by the nervous system, cardiac muscle contraction will continue in excised hearts with no connection to the central nervous system. Tunicate hearts have two noninnervated, myogenic pacemakers, one at each end of the peristaltic pulsating vessel. Separately, each pacemaker causes a series of normal beats followed by a sequence of abnormal ones; together, they provide periodic reversals of blood flow.

The control of heartbeat in most other invertebrates is neurogenic, and one or more nerve ganglia with attendant nerve fibres control contraction. Removal of the ganglia stops the heart, and the administration of acetylcholine increases its rate. Adult heart control may be neurogenic but not necessarily in all stages in the life cycle. The embryonic heart may show myogenic peristaltic contractions prior to innervation.

Heart rate differs markedly among species and under different physiological states of a given individual. In general it is lower in sedentary or sluggish animals and faster in small ones. The rate increases with internal pressure but often reaches a plateau at optimal pressures. Normally, increasing the body temperature 10° C (50° F) causes an increase in heart rate of two to three times. Oxygen availability and the presence of carbon dioxide affect the heart rate, and during periods of hypoxia the heart rate may decrease to almost a standstill to conserve oxygen stores.

The time it takes for blood to complete a single circulatory cycle is also highly variable but tends to be much longer in invertebrates than in vertebrates. For example, in isolation, the circulation rate in mammals is about 10 to 30 seconds, for crustaceans about one minute, for cockroaches five to six minutes, and for other insects almost 30 minutes.

Circulatory cycles

ACOELOMATES AND PSEUDOCOELOMATES

At the simplest levels of metazoan organization, where there are at most two cell layers, the tissues are arranged in sheets. The necessity for a formal circulatory system does not exist, nor are the mesodermal tissues, normally forming one, present. The addition of the mesodermal layer allows greater complexity of organ development and introduces further problems in supplying all cells with their essential requirements.

Invertebrate phyla have developed a number of solutions to these problems; most but not all involve the development of a circulatory system: as described above, sponges and cnidarians (Figure 1D) permit all cells direct access to environmental water. Among the acoelomate phyla, the members of Platyhelminthes (flatworms) have no body cavity, and the space between the gut and the body wall, when present, is filled with a spongy organ tissue of mesodermal cells through which tissue fluids may percolate. Dorsoventral (back to front) flattening, ramifying gut ceca (cavities open at one end), and, in the endoparasitic flatworm forms, glycolytic metabolic pathways (which release metabolic energy in the absence of oxygen) reduce diffusion distances and the need for oxygen and allow the trematodes and turbellarians of this phylum to maintain their normal metabolic rates in the absence of an independent circulatory system. The greatly increased and specialized body surface of the cestodes (tapeworms) of this phylum has allowed them to dispense with the gut as well. Most of the other acoelomate invertebrate animals are small enough that direct diffusion constitutes the major means of internal transport.

One acoelomate phylum, Nemertea (proboscis worms), contains the simplest animals possessing a true vascular system (Figure 1C). In its basic form there may be only two vessels situated one on each side of the straight gut. The vessels unite anteriorly by a cephalic space and posteriorly by an anal space lined by a thin membrane. The system is thus closed, and the blood does not directly bathe the tissues. The main vessels are contractile, but blood flow is irregular and it may move backward or forward within an undefined circuit. The blood is usualiy colourless, although some species contain pigmented blood cells

whose function remains obscure; phagocytic amoebocytes are usually also present. Although remaining fundamentally simple, the system can grow more elaborate with the addition of extra vessels.

The pseudocoelom

Pseudocoelomate metazoans have a fluid-filled body cavity, the pseudocoelom, which, unlike a true coelom, does not have a cellular peritoneal lining. Most of the pseudocoelomates (*e.g.*, the classes Nematoda and Rotifera) are small and none possess an independent vascular system. Muscular body and locomotor movements may help to circulate nutrients within the pseudocoelom between the gut and the body wall. The lacunar system of channels within the body wall of the gutless acanthocephalans (spiny-headed worms) may represent a means of circulation of nutrients absorbed through the body wall. Hemoglobin has been found in the pseudocoelomic fluid of a number of nematodes, but its precise role in oxygen transport is not known.

COELOMATES

Despite their greater potential complexity, many of the minor coelomate phyla (*e.g.*, Pogonophora, Sipuncula, and Bryozoa) contain small animals that rely on direct diffusion and normal muscular activity to circulate the coelomic fluid. All of the major and some of the minor phyla have well-developed blood vascular systems, often of open design.

Annelida. While some small segmented worms of the phylum Annelida have no separate circulatory system, most have a well-developed closed system. The typical arrangement is for the main contractile dorsal vessel to carry blood anteriorly while a number of vertical segmental vessels, often called hearts, carry it to the ventral vessel, in which it passes posteriorly (Figure 1E). Segmental branches supply and collect blood from the respiratory surfaces, the gut, and the excretory organs.

There is, however, great scope for variation on the basic circulatory pattern. Many species have a large intestinal sinus rather than a series of vessels supplying the gut, and there may be differences along the length of a single individual. The posterior blood may flow through an intestinal sinus, the medial flow through a dense capillary plexus, and the anterior flow through typical segmental capillaries. Much modification and complication may occur in species in which the body is divided into more or less distinct regions with specific functions.

Many polychaete worms (class Polychaeta), especially the fanworms but also representatives of other families, have many blind-ending contractile vessels. Continual reversals of flow within these vessels virtually replace the normal continuous-flow capillary system.

In most leeches (class Hirudinea), much of the coelomic space is filled with mesodermal connective tissue, leaving a series of interconnecting coelomic channels. A vascular system comparable to other annelids is present in a few species, but in most the coelomic channels containing blood (strictly coelomic fluid) have taken over the function of internal transport, with movement induced by contraction of longitudinal lateral channels.

Annelid blood

The blood of many annelids contains a respiratory pigment dissolved in the plasma, and the coelomic fluid of others may contain coelomic blood cells containing hemoglobin. The most common blood pigments are hemoglobin and chlorocruorin, but their occurrence does not fit any simple evolutionary pattern. Closely related species may have dissimilar pigments, while distant relatives may have similar ones. In many species the pigments function in oxygen transport, but in others they are probably more important as oxygen stores for use during periods of hypoxia.

In addition to internal circulation, many polychaete worms also set up circulatory currents for feeding and respiration. Tube-dwelling worms may use muscular activity to pass a current of oxygenated water containing food through their burrows, while filter-feeding fanworms use ciliary activity to establish complicated patterns of water flow through their filtering fans.

Echiura. The phylum Echiura (spoonworms) contains a small number of marine worms with a circulatory system of similar general pattern to that of the annelids. Main dorsal and ventral vessels are united by contractile circumintestinal vessels that pump the colourless blood. Coelomic fluid probably aids in oxygen transport and may contain some cells with hemoglobin.

Mollusca. With the exception of the cephalopods, members of the phylum Mollusca have an open circulatory system (Figure 2A). The chambered, myogenic heart normally has a pair of posterior auricles draining the gills and an anterior ventricle that pumps the blood through the anterior aorta to the tissue sinuses, excretory organs, and gills. Many gastropods lack a second set of gills, and in these the right auricle is vestigial or absent. The heart is enclosed within the coelomic cavity, which also surrounds part of the intestine. The single aorta branches, and blood is delivered into arterial sinuses, where it directly bathes the tissues. It is collected in a large venous cephalopedal sinus and, after passing through the excretory organs, returns to the gills. The hydrostatic pressure that develops in the blood sinuses of the foot, especially of bivalve mollusks, is used in locomotion. Blood flow into the foot is controlled by valves: as the pressure increases, the foot elongates and anchors into the substratum; muscular contraction then pulls the animal back down to the foot. This type of locomotion is seen most commonly in burrowing species, who move through the substratum almost exclusively by this means.

Like the annelids, many mollusks, especially the more sedentary bivalves, set up local feeding and respiratory currents. Fluid movement through the mantle cavity normally depends on muscular pumping through inhalant and exhalant siphons. Within the cavity itself, however, ciliary activity maintains continuous movement across the gill surfaces, collecting food particles and passing them to the mouth.

The cephalopods are more active than other mollusks

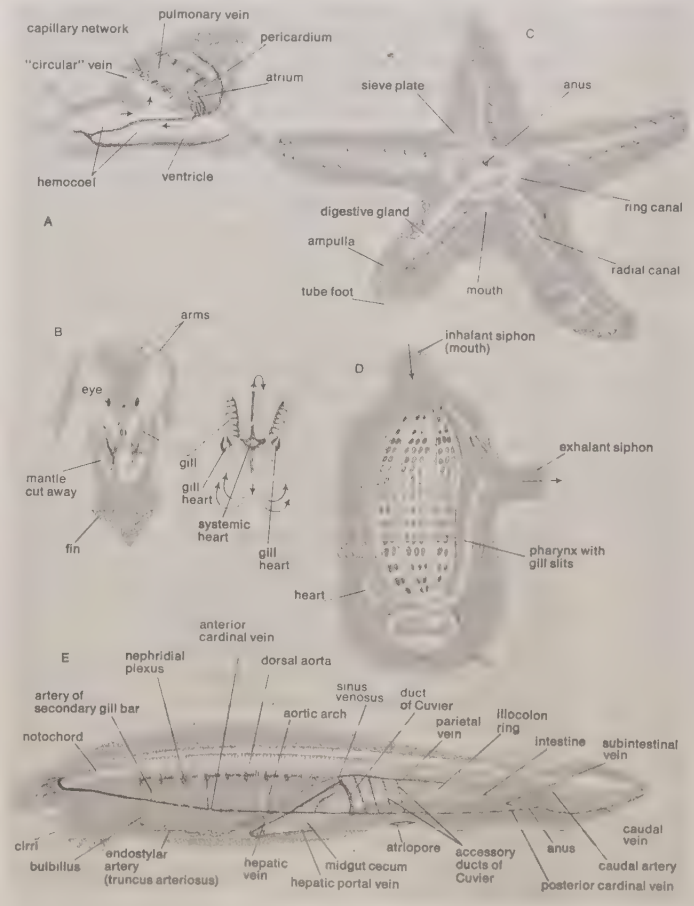

Figure 2: Circulatory system of (A) snail, (B) cephalopod, (C) starfish, (D) tunicate, (E) amphioxus.

Cephalopods

and consequently have higher metabolic rates and circulatory systems of a higher order of organization (Figure 2B). These systems are closed with distinct arteries, veins, and capillaries; the blood (6 percent of body weight) remains distinct from the interstitial fluid (15 percent of body weight). These relative percentages of body weight to blood volume are similar to those of vertebrates and differ markedly from those of species with open circulatory systems, in which hemolymph may constitute 40 to 50 percent of body weight.

The cephalopod heart usually consists of a median ventricle and two auricles. Arterial blood is pumped from the ventricle through anterior and posterior aortas that supply the head and body, respectively. It is passed through the capillary beds of the organs, is collected, and is returned to the heart through a major venous vessel, the vena cava. The vena cava bifurcates (divides into two branches) near the excretory organs, and each branch enters the nephridial sac before passing to the accessory hearts situated at the base of the gills. Veins draining the anterior and posterior mantle and the gonads merge with the branches of the vena cava before reaching the branchial hearts. Contraction of the branchial hearts increases the blood pressure and forces blood through the gill capillaries. The auricles then drain the gills of oxygenated blood.

The blood of most mollusks, including cephalopods, contains hemocyanin, although a few gastropods use hemoglobin. In the cephalopods the pigment unloads at relatively high oxygen pressures, indicating that it is used to transport rather than store oxygen.

Rapid cephalopod locomotion depends almost entirely on water pressure. During inhalation, muscular activity within the mantle wall increases the volume of the mantle cavity and water rushes in. Contraction of the circular mantle muscles closes the edge of the mantle and reduces its volume, forcing the enclosed water through the mobile funnel at high pressure. The force of water leaving the funnel propels the animal in the opposite direction.

Brachiopoda. Members of the phylum Brachiopoda (lamp shells) superficially resemble the mollusks but are not related. The circulatory system of brachiopods is open and consists of a small contractile heart situated over the gut, from which anterior and posterior channels supply sinuses in the wall of the gut, the mantle wall, and the reproductive organs.

Arthropoda. The blood vascular system of arthropods is open. The coelom is much reduced, and most of the spaces in the arthropod body are hemocoels. The tubular heart is dorsal and contained in a pericardial sinus. Blood is pumped from the heart through a series of vessels (arteries) that lead to the tissue sinuses. Although the blood flows freely through the tissues it may, especially in the larger species, be directed by membranes along a more or less constant pathway. The blood collects in a ventral sinus from which it is conducted back to the heart through one or more venous channels.

Variations in the circulatory patterns of the different classes of the phylum Arthropoda largely reflect the method of respiratory exchange and consequent function of the blood vascular system. Most of the aquatic species of the class Crustacea (Figure 1F) have gills with a well-developed circulatory system, including accessory hearts to increase blood flow through the gills. A small number of species lack gills and a heart, and oxygen is absorbed through the body surface; bodily movements or peristaltic gut contractions circulate the blood within the tissue spaces.

Oxygen transport in insects

In the mainly terrestrial class Insecta, the role of oxygen transport has been removed from the blood and taken over by the ramifying tracheal system that carries gaseous atmospheric oxygen directly to the consuming tissues (Figure 1G). Insects are able to maintain the high metabolic rates necessary for flight while retaining a relatively inefficient circulatory system.

Among the chelicerate (possessing fanglike front appendages) arthropods (for example, scorpions, spiders, ticks, and mites), the horseshoe crab, *Limulus*, has a series of book gills (gills arranged in membranous folds) on either side of the body into which blood from the ventral sinus passes for oxygenation prior to return to the heart. The largely terrestrial arachnids may have book lungs that occupy a similar position in the circulatory pathway, a tracheal system comparable to that of insects, or, in the case of smaller species, reduced tracheal and vascular systems in which contractions of the body muscles cause blood circulation through the sinus network.

The legs of spiders are unusual because they lack extensor muscles and because blood is used as hydraulic fluid to extend the legs in opposition to flexor muscles. The blood pressure of a resting spider is equal to that of a human being and may double during activity. The high pressure is maintained by valves in the anterior aorta and represents an exception to the general rule that open circulatory systems only function at low pressure.

Echinodermata. The circulatory systems of echinoderms (sea urchins, starfishes, and sea cucumbers) are complicated as they have three largely independent fluid systems. The large fluid-filled coelom that surrounds the internal organs constitutes the major medium for internal transport. Circulatory currents set up by the ciliated cells of the coelomic lining distribute nutrients from the gut to the body wall. Phagocytic coelomocytes are present, and in some species these contain hemoglobin. The coelomic fluid has the same osmotic pressure as seawater, and the inability to regulate that pressure has confined the echinoderms to wholly marine habitats.

The blood-vascular (hemal) system is reduced and consists of small, fluid-filled sinuses that lack a distinct lining. The system is most highly developed in the holothurians (sea cucumbers), in which it consists of an anterior hemal ring and radial hemal sinuses. The most prominent features are the dorsal and ventral sinuses, which accompany the intestine and supply it through numerous smaller channels. The dorsal sinus is contractile, and fluid is pumped through the intestinal sinuses into the ventral sinus and thence to the hemal ring. Most members of the class Holothuroidea have a pair of respiratory trees, located in the coelom on either side of the intestine, which act as the major sites for respiratory exchange. Each tree consists of a main tubular trunk with numerous side branches, each ending in a small vesicle. Water is passed through the tubules by the pumping action of the cloaca. The branches of the left tree are intermingled with the intestinal hemal sinuses and provide a means of oxygenating the blood via the coelomic fluid. The right tree is free in the coelomic fluid and has no close association with the hemal system. Respiratory exchange in other echinoderms is through thin areas of the body wall, and the hemal system tends to be reduced.

Sea cucumbers

The water vascular system of echinoderms is best developed in the starfishes and functions as a means of locomotion and respiratory exchange. The entire system consists of a series of fluid-filled canals lined with ciliated epithelium and derived from the coelom. The canals connect to the outside through a porous, button-shaped plate, called the madreporite, which is united via a duct (the stone canal) with a circular canal (ring canal) that circumvents the mouth (Figure 2C). Long canals radiate from the water ring into each arm. Lateral canals branch alternately from the radial canals, each terminating in a muscular sac (or ampulla) and a tube foot (podium), which commonly has a flattened tip that can act as a sucker. Contraction of the sac results in a valve in the lateral canal closing as the contained fluid is forced into the podium, which elongates. On contact with the substratum, the centre of the distal end of the podium is withdrawn, resulting in a partial vacuum and adhesion that is aided by the production of a copious adhesive secretion. Withdrawal results from contraction of the longitudinal muscles of the podia.

Hemichordata. Among the phylum Hemichordata are the enteropneusts (acornworms), which are worm-shaped inhabitants of shallow seas and have a short, conical proboscis, which gives them their common name. The vascular system of the Enteropneusta is open, with two main contractile vessels and a system of sinus channels. The colourless blood passes forward in the dorsal vessel, which widens at the posterior of the proboscis into a space, the contractile wall of which pumps the blood into the

glomerulus, an organ formed from an in-tucking of the hind wall of the proboscis cavity. From the glomerulus the blood is collected into two channels that lead backward to the ventral longitudinal vessel. This vessel supplies the body wall and gut with a network of sinuses that eventually drain back into the dorsal vessel.

Chordata. The phylum Chordata contains all animals that possess, at some time in their life cycles, a stiffening rod (the notochord), as well as other common features. The subphylum Vertebrata is a member of this phylum and will be discussed later (see below *The vertebrate circulatory system*). All other chordates are called protochordates and are classified into two groups: Tunicata and Cephalochordata.

The blood-vascular system of the tunicates, or sea squirts (Figure 2D), is open, the heart consisting of no more than a muscular fold in the pericardium. There is no true heart wall or lining and the whole structure is curved or U-shaped, with one end directed dorsally and the other ventrally. Each end opens into large vessels that lack true walls and are merely sinus channels. The ventral vessel runs along the ventral side of the pharynx and branches to form a lattice around the slits in the pharyngeal wall through which the respiratory water currents pass. Blood circulating through this pharyngeal grid is provided with a large surface area for gaseous exchange. The respiratory water currents are set up by the action of cilia lining the pharyngeal slits and, in some species, by regular muscular contractions of the body wall. Dorsally, the network of pharyngeal blood vessels drains into a longitudinal channel that runs into the abdomen and breaks up into smaller channels supplying the digestive loop of the intestine and the other visceral organs. The blood passes into a dorsal abdominal sinus that leads back to the dorsal side of the heart. The circulatory system of the sea squirt is marked by periodic reversals of blood flow caused by changes in the direction of peristaltic contraction of the heart.

Blood of sea squirts

Sea squirt blood has a slightly higher osmotic pressure than seawater and contains a number of different types of amoebocytes, some of which are phagocytic and actively migrate between the blood and the tissues. The blood of some sea squirts also contains green cells, which have a unique vanadium-containing pigment of unknown function.

Amphioxus (*Branchiostoma lanceolatum*) is a cephalochordate that possesses many typical vertebrate features but lacks the cranial cavity and vertebral column of the true vertebrate. Its circulatory pattern differs from that of most invertebrates as the blood passes forward in the ventral and backward in the dorsal vessels (Figure 2E). A large sac, the sinus venosus, is situated below the posterior of the pharynx and collects blood from all parts of the body. The blood passes forward through the subpharyngeal ventral aorta, from which branches carry it to small, accessory, branchial hearts that pump it upward through the gill arches. The oxygenated blood is collected into two dorsal aortas that continue forward into the snout and backward to unite behind the pharynx. The single median vessel thus formed branches to vascular spaces and the intestinal capillaries. Blood from the gut collects in a median subintestinal vein and flows forward to the liver, where it passes through a second capillary bed before being collected in the hepatic vein and passing to the sinus venosus. Paired anterior and posterior cardinal veins collect blood from the muscles and body wall. These veins lead, through a pair of common cardinal veins (duct of Cuvier), to the sinus venosus.

There is no single heart in the amphioxus, and blood is transported by contractions that arise independently in the sinus venosus, branchial hearts, subintestinal vein, and other vessels. The blood is nonpigmented and does not contain cells; oxygen transport is by simple solution in the blood.

(B.E.Ma.)

The vertebrate circulatory system

THE BASIC VERTEBRATE PATTERN

The plan. All vertebrates have circulatory systems based on a common plan (Figure 3A), and so vertebrate systems show much less variety than do those of invertebrates. Although it is impossible to trace the evolution of the circulatory system by using fossils (because blood vessels do not fossilize as do bones and teeth), it is possible to theorize on its evolution by studying different groups of vertebrates and their developing embryos. Many of the variations from the common plan are related to the different requirements of living in water and on land.

The heart. The vertebrate heart lies below the alimentary canal in the front and centre of the chest, housed in its own section of the body cavity. During the development of an embryo, the heart first appears below the pharynx, and although it may also be in this position in adult animals, the heart often moves posteriorly as the animal grows and matures.

Development of the heart

The heart is basically a tube made of special muscle (cardiac muscle) that is not found anywhere else in the body. This cardiac muscle beats throughout life with its own automatic rhythm. Deoxygenated blood from the body is brought by veins into the most posterior part of the heart tube, the sinus venosus (Figure 3B). From there it passes forward into the atrium, the ventricle, and the conus arteriosus (called the bulbus cordis in embryos), and eventually to the arterial system. The blood is pushed through the heart because the various parts of the tube contract in sequence. As the heart develops from embryo to adult, each part of the tube becomes a chamber, separated from the others by valves, so that blood can neither flow backward in the system nor reenter the heart from the arteries. As the heart grows, it bends into an "S" shape, so that the sinus venosus and atrium lie above the ventricle and conus arteriosus.

The blood vessels. Gill slits are a fundamental feature of all vertebrate embryos, including humans. With few exceptions, there are six gill slits on each side. Blood leaving the heart travels from the conus arteriosus into the ventral aorta, which branches to send six pairs of arteries between the gill slits. The arterial branches join the dorsal aorta above the alimentary canal. Anterior to the gill slits, the ventral aorta branches again, forming two external carotid arteries that supply the ventral part of the head.

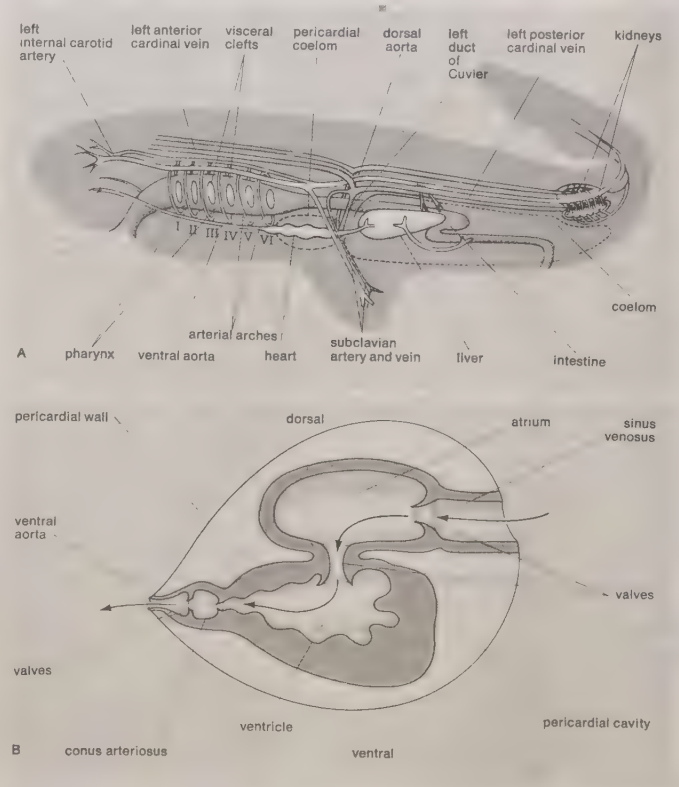

Figure 3: (A) Lateral view of a hypothetical primitive vertebrate showing arterial and venous systems in relation to each other and to the alimentary canal. (B) Left side longitudinal section of the basic form of vertebrate heart; arrow represents the direction of blood flow.

Two internal carotids, which are the anterior extensions of the dorsal aorta, supply the brain in the dorsal part of the head.

Deoxygenated blood collects in capillaries and then drains into larger and larger veins, which take it from various parts of the body to the heart. Of these, the anterior and posterior cardinal veins, each with left and right components, take blood to the heart from the front and rear of the body, respectively (Figure 3A). They lie dorsal to the alimentary canal, while the heart lies ventral to it. There is a common cardinal vein on each side, often called the duct of Cuvier, which carries blood ventrally into the sinus venosus. Various other veins join the cardinal veins from all over the body. The ventral jugular veins drain the lower part of the head and take blood directly into the common cardinal veins.

Lower vertebrates have two so-called portal systems, areas of the venous system that begin in capillaries in tissues and join to form veins, which divide to produce another capillary network en route to the heart. They are called the hepatic (liver) and renal (kidneys) portal systems. The hepatic system is important because it collects blood from the intestine and passes it to the liver, the centre for many chemical reactions concerned with the absorption of food into the body and the control of substances entering the general circulation. The function of the renal portal system is less clear, but it involves two veins that pass from the caudal vein to the kidneys, where they break up into capillaries.

Coronary circulation

The coronary circulation is that which supplies the heart muscle itself. It is of crucial importance, for the heart must never stop beating. Cardiac muscle needs oxygen from early in embryonic development until death. In mammals the coronary blood supply comes from the aorta, close to the heart. In evolutionary terms, this was not always so; many lower vertebrates, including agnathans and amphibians, have no specialized coronary arteries. The heart obtains its oxygen from blood passing through it. Fish have well-developed coronary vessels that arise from various sources, but ultimately from the efferent branchial system.

The introduction of lungs changed the site of oxygenation of the blood. In lungfishes coronary arteries arise from those anterior arterial arches receiving the most oxygenated blood from the heart. In reptiles coronary arteries branch from the systemic arch, but their position of origin varies. In some species they arise close to the heart, as in birds and mammals. Coronary veins generally run beside corresponding arteries but diverge from them to enter the main venous supply to the right atrium, or to the sinus venosus in fishes.

Evolutionary trends. Conventional classification divides vertebrates into two main groups—Gnathostomata, or vertebrates with jaws, and Agnatha, or those without jaws (the lampreys and hagfishes). This is a fundamental division, for agnathans also lack paired fins and scales. Agnathans are regarded as the most primitive group of vertebrates, not least because they appear first in the fossil record, before jawed fishes. Their circulatory systems differ in various ways from those of jawed vertebrates.

Circulation in agnathans. In the lamprey heart the atrium and ventricle are side by side, with the sinus venosus entering the atrium laterally. Nonmuscular valves prevent backflow of blood, and the conus arteriosus contains no cardiac muscle. There is no separate coronary blood supply, and the heart must obtain its oxygen from the blood as it goes through.

The arterial system in agnathans is most obviously modified because there are more than six sets of gills. Eight branches emerge from the ventral aorta, which splits into two, unlike the single vessel in most vertebrates with gill slits. Oxygenated blood from the gills is then collected into eight efferent vessels, which join to form a dorsal aorta, single for most of its length. Internal carotid arteries arise from the dorsal aorta, but the ventral part of the head is supplied from anterior efferent branchial (gill) vessels, not from the anterior part of the ventral aorta.

The venous system does not include a renal portal section, and there is asymmetry of the common cardinal veins, which take blood from the dorsal anterior and posterior cardinal veins down to the ventral heart. In embryos there are two of these, one on each side of the body; in lampreys, the left one disappears during development, while in hagfishes the right one disappears. Hagfishes also have accessory hearts in the venous system at several points. No other vertebrate has these structures.

It is not clear why the circulatory system of agnathans differs in these ways from the basic vertebrate plan. It is important to remember, however, that lampreys and hagfishes are specialized descendants of what was once a more diverse and widespread group of animals. Their circulatory systems may be less similar to the basic vertebrate plan than those of their ancestors because of their present mode of life.

Circulation in jawed vertebrates. Although clearly related to its mode of life, the blood system of a species also reflects its evolutionary history. The most significant change that occurred during early vertebrate evolution was the appearance of animals that could live and breathe on land. The first of these were the amphibians. Reptiles became even more independent of water because of their waterproof skins and shelled eggs, and from them evolved the most sophisticated land vertebrates, the mammals and birds. Obtaining oxygen entirely from air, instead of from water, involved drastic changes in the circulatory system.

Vertebrate evolution

Land vertebrates use their lungs to exchange carbon dioxide for oxygen from the air. Lungs may have evolved from a structure in fishes called the swim bladder, a sac that grows out from the anterior part of the gut. Fishes use it for buoyancy control, but it is possible that it was originally useful as an accessory for respiration. The problem is that lungs are found at a different site in the circulatory system from that of the gills, where oxygenation occurs in fishes. Instead of circulating around the body, as it does in fishes, oxygenated blood from the lungs returns to the heart. Therefore, in evolutionary terms, if mixing of oxygenated and deoxygenated blood was to be avoided in the heart, alterations to its structure had to occur. Land vertebrates developed lungs, a new vein (the pulmonary vein) to take blood from them to the heart, and a double circulation, whereby the heart is effectively divided into two halves—one-half concerned with pumping incoming deoxygenated blood from the body to the lungs and the

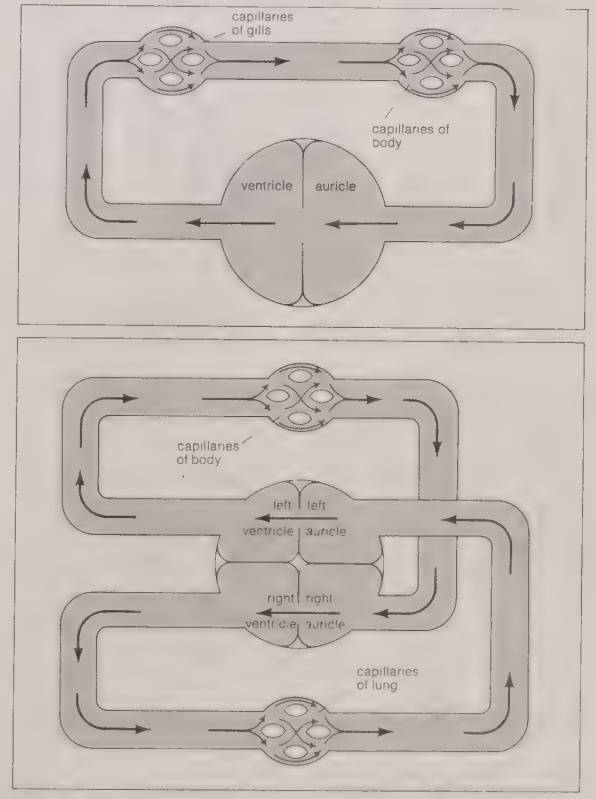

Figure 4: (Top) Single circulation of a fish; (bottom) double circulation of birds and mammals.

other with pumping oxygenated blood from the lungs around the body (Figure 4).

There are also modifications in the arterial and venous systems related to the appearance of lungs in the circulation. In the venous system, the paired posterior cardinal veins are replaced by a single posterior vena cava, and the renal portal system disappears. The main modifications to the basic arterial pattern involve what are the gill arteries of fishes. The anterior of these became responsible for carrying oxygenated blood to the head and to the brain; the intermediate arteries for carrying blood to the dorsal aorta, and so around the body; and the posterior arteries for carrying deoxygenated blood to the lungs.

Fishes

In fishes the four chambers of the heart are all well developed. Blood passes in sequence through the sinus venosus, atrium, ventricle, and conus arteriosus. The ventricle is the main pumping chamber, as it is in the hearts of all land vertebrates. During the evolution of the heart, the ventricle and atrium came to predominate; the sinus venosus became part of the atrium, while the conus arteriosus was incorporated into the ventricle. The atrium itself became a double structure—the two auricles—as did the ventricle, but the conversion of the ventricle into two chambers occurred later in evolution than the division of the atrium.

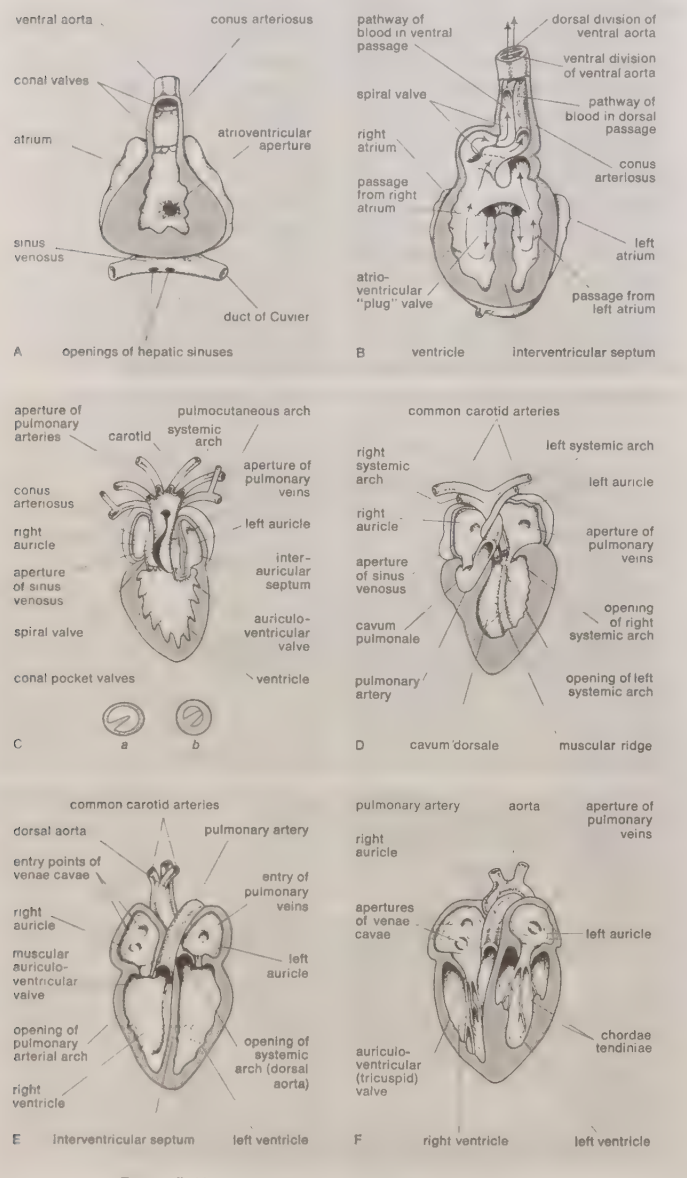

Figure 5: *Ventral dissections of vertebrate hearts.* (A) Dogfish (a shark); (B) lungfish; (C) frog (inset shows transverse sections of conus arteriosus in diastole [*a*] and systole [*b*]); (D) lizard; (E) bird; (F) mammal.

MODIFICATIONS AMONG THE VERTEBRATE CLASSES

Fishes. The hearts of fishes show little modification from the basic plan, except that lungfish hearts tend to become subdivided (Figure 5B). In them, the oxygenated blood carried by the pulmonary vein does not enter the sinus venosus along with the deoxygenated blood from the body. Instead, the oxygenated blood remains separate and enters the left side of the atrium. The atrium is partially divided into two auricles, and the ventricle also has a partial septum. Lungfishes show further signs of circulatory developments in their venous system (Figure 6). As in land vertebrates, there is a median posterior vena cava, and the posterior cardinal veins are reduced.

The arterial system of fishes is also altered from the basic plan. First there are the afferent (leading to) and efferent (leading from) parts of the gill (branchial) blood vessels. Each pair of blood vessels looping up between a pair of gills is called an arterial arch. During the development of embryos, the arterial arches become interrupted by capillaries in the gills. Thus, each arch consists of a ventral afferent section that brings blood to the gills from the heart and a dorsal efferent section that collects blood from the gill capillaries and carries it to the dorsal aorta. The whole circulatory system is a one-way arrangement, with the heart pumping only deoxygenated blood from the body forward to the gills to be oxygenated and redistributed to the body.

Oxygenation in fishes

Although six gill slits appear in embryos, few adult fishes retain all six. The first and most anterior gill slit in the series becomes the spiracle, and the first branchial arch is much modified; parts of it disappear altogether (Figure 6). The second branchial arch is variable in its presence in different fishes. In general, therefore, adult fishes often have only four of the six original arterial arches found in embryos. The external carotid arteries also show modifications. Instead of arising from the anterior part of the ventral aorta, they become connected with the efferent portion of the second branchial arch. This change ensures that, despite modifications to the most anterior of the arterial arches, blood just oxygenated in the gills will reach the head.

It may be that the prevalence of poorly oxygenated water in certain habitats explains the evolution of lungs and, hence, of land vertebrates. Fishes also have evolved accessory structures for obtaining oxygen from the air. These are often modified gill chambers, with dense capillary networks. Even the intestine may be involved, as in the loach *Haplosternum*.

The swim bladder

Except for sharks and their relatives (elasmobranchs), most fishes have a swim bladder, the structure from which lungs may have evolved. Although its prime function in fishes is to control buoyancy, the swim bladder may also act as an oxygen reserve, for the gas in it often contains a high concentration of oxygen derived from the blood's own supply. Blood to the swim bladder usually comes from the dorsal aorta. One African fish, *Polypterus,* uses its swim bladder for respiration, and the veins from it join the posterior cardinal veins close to the heart. These swim bladder veins are almost where pulmonary veins would be expected to be, if they were bringing oxygenated blood from lungs straight to the heart.

The lungfishes have gone further in adapting their circulatory systems to the presence of lungs, although the different species do not breathe air to the same extent. Some of their modifications foreshadow the changes that have taken place in amphibians. The divided atrium of the lungfish heart (Figure 5B) receives blood from the body on the right side and from the lungs on the left. The conus is large and is divided by a complex system of valves arranged in a spiral pattern and called the spiral valve. The ventral aorta is also subdivided internally. The result is that oxygenated blood from the left side of the ventricle is directed into the ventral division of the ventral aorta and passes to the anterior of the arterial arches, while deoxygenated blood from the right side of the ventricle is directed into the two most posterior arterial arches and passes mainly to the lungs.

Four arterial arches are present even in the lungfish species most dependent on breathing air (*Lepidosiren;*

Figure 6), where gills still exist. These are arches three to six of the original series of six present in fish embryos. Their arrangement is largely unaffected by the presence of lungs, except that the gills may be reduced and the arteries may pass straight through without intervening capillaries. Arches five and six, however, join together before entering the dorsal aorta and give rise to a large pulmonary artery to the lungs. Thus, in lungfishes, lungs and gills can be seen working side by side.

The circulatory systems of lungfishes are strikingly similar to those of amphibians, and although lungfishes do not seem to have been amphibian ancestors, they are related to fishes that were. It is likely that several groups of ancient fishes had lungs, partially divided hearts, and ventral aortas, and from one of these groups arose the land vertebrates.

Amphibians. Modern amphibians are characterized by the flexibility of their gaseous exchange mechanisms. Amphibian skin is moistened by mucous secretions and is well supplied with blood vessels. It is used for respiration to varying degrees. When lungs are present, carbon dioxide may pass out of the body across the skin, but in some salamanders there are no lungs and all respiratory exchanges occur via the skin. Even in such animals as frogs, it seems that oxygen can be taken up at times by the skin, under water for example. Therefore, regulation of respiration occurs within a single species, and the relative contribution of skin and lungs varies during the life of the animal.

The amphibian heart

The amphibian heart is generally of a tripartite structure, with a divided atrium but a single ventricle (Figure 5C). The lungless salamanders, however, have no atrial septum, and one small and unfamiliar group, the caecilians, has signs of a septum in the ventricle. It is not known whether the original amphibians had septa in both atrium and ventricle. They may have, and the absence of septa in many modern forms may simply be a sign of a flexible approach to the use of skin or lung, or both, as the site of oxygen exchange. In addition, the ventricle is subdivided by muscular columns into many compartments that tend to prevent the free mixing of blood.

The conus arteriosus is muscular and contains a spiral valve. Again, as in lungfishes, this has an important role in directing blood into the correct arterial arches. In the frog, *Rana,* venous blood is driven into the right atrium of the heart by contraction of the sinus venosus, and it flows into the left atrium from the lungs. A wave of contraction then spreads over the whole atrium and drives blood into the ventricle, where blood from the two sources tends to remain separate. Separation is maintained in the spiral valve, and the result is similar to the situation in lungfishes. Blood from the body, entering the right atrium,

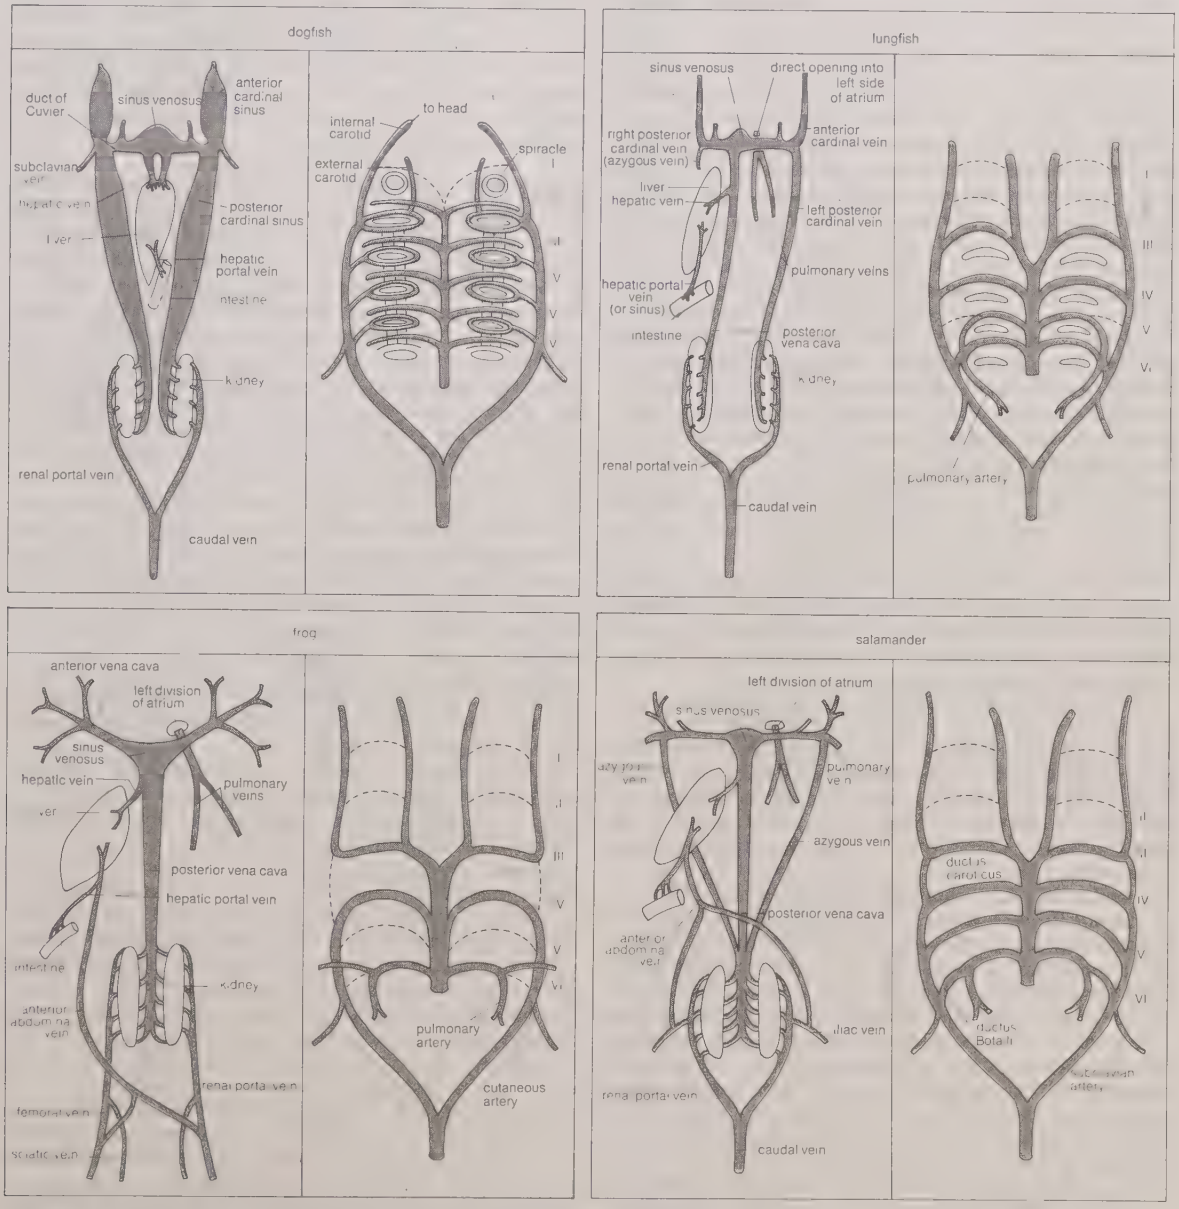

Figure 6: Vascular systems of representative vertebrates—dogfish, lungfish, frog, and salamander—showing (at left) the venous system and (at right) the arterial system as seen in ventral views.

tends to pass to the lungs and skin for oxygenation; that from the lungs, entering the left atrium, tends to go to the head. Some mixing does occur, and this blood tends to be directed by the spiral valve into the arterial arch leading to the body.

Blood returning from the skin does not enter the circulation at the same point as blood from the lungs. Thus, oxygenated blood arrives at the heart from two different directions—from the sinus venosus, to which the cutaneous (skin) vein connects, and from the pulmonary vein. Both right and left atria receive oxygenated blood, which must be directed primarily to the carotid arteries supplying the head and brain. It is likely that variable shunting of blood in the ventricle is important in ensuring this. A ventricular septum would inhibit shunting; it is at least possible that its absence in amphibians is not a primitive feature but a secondary adaptation to variable gas-exchange mechanisms.

The amphibian venous system shows various features that are characteristic of land vertebrates. The posterior cardinal veins are replaced by a posterior vena cava, but they are still visible in salamanders. There is a renal portal system, and an alternative route back to the heart from the legs is provided by an anterior abdominal vein that enters the hepatic portal vein to the liver (Figure 6).

Amphibian larvae and the adults of some species have gills. There are four arterial arches in salamanders (urodeles) and three in frogs (anurans; Figure 6). These are three through six of the original series, the fifth disappearing in adult frogs. There is no ventral aorta, and the arterial arches arise directly from the conus—an important feature, given that the conus and its spiral valve control the composition of blood reaching each arterial arch. The names given to the three arterial arches of frogs are those used in all land vertebrates, including mammals. They are the carotid (the third), systemic (the fourth), and pulmonary (the sixth) arches. Blood to the lungs (and skin in frogs) is always carried by the sixth arterial arch, which loses its connection to the dorsal aorta. All land vertebrates supply their lungs with deoxygenated blood from this source.

Lungs

Reptiles. Unlike lungfishes and amphibians, reptiles depend entirely on their lungs for respiration. Gills and skin do not provide additional sources of oxygen. Only the crocodiles, however, truly approach birds and mammals in their almost complete "double" circulation. Because of the development of a neck and relative elongation of that region of the body, the heart may be displaced posteriorly and the arrangement of arteries and veins may be altered accordingly. In general, however, the circulatory system resembles that in frogs (Figures 6 and 7).

The reptilian heart

Various changes can be seen in the reptilian heart. The left atrium is smaller than the right and always completely separate from it (Figure 5D). The sinus venosus is present but small. The ventricle is variously subdivided in different groups. Three arterial trunks arise directly from the ventricle, the conus having been partly incorporated into it. The three trunks are the right and left systemic arches and the pulmonary arch. The carotid arch is a branch of the right systemic arch. When the ventricle is actually beating, there is functional separation of blood from the two atria so that most oxygenated blood flows to the carotid arteries and hardly mixes with deoxygenated blood going to the lungs.

Crocodiles are the only living representatives of the archosaurian reptiles, the group that included the dinosaurs and from which birds evolved. Crocodiles have a complete ventricular septum, producing two equally sized chambers. The blood from the right and left atria is not mixed; despite this, there is an opening at the base of the right and left systemic arches, and blood can be shunted between the two. This is important during diving, when blood flow to the lungs is decreased. The crocodile heart is situated so posteriorly that the subclavian artery, which would normally arise from the dorsal aorta at the level of the systemic arch, arises from the carotid artery.

Birds. Bird circulatory systems have many similarities to those of reptiles, from which they evolved. The changes that have occurred are more of degree than of kind. The heart is completely divided into right and left sides (Figure 5E). The sinus venosus is incorporated into the right auricle and becomes the sinoauricular node. It is from this point that the heartbeat is initiated. There is no conus, and only two vessels leave the divided ventricle. These are the pulmonary artery from the right side and the systemic arch from the left. The systemic arch is asymmetrical—the main difference in this area between birds and lizards. Only the right part of the systemic arch is present, the left being suppressed (Figure 7). The arterial arches are no longer bilaterally symmetrical. Another difference between birds and lizards is found in the venous circulation: the renal portal system is reduced in birds.

Mammals. Mammals also evolved from reptiles, but not from the same group as did birds, and must have developed their double circulation independently from early reptiles. Nevertheless, several parallel changes occurred, such as the common incorporation of the sinus venosus into the right auricle. The most striking manifestation of different origins is seen in the mammalian aorta, which leaves the left ventricle and curves to the left (Figure 5F). The aorta corresponds to the left half of the systemic arch, while the right is missing (Figure 7). The carotid arteries arise from the left systemic arch (aorta), though their precise position varies among mammals. The arterial system is asymmetric, as in birds, but in the opposite way.

The heart of both mammals and birds is a double pump, powering two systems of vessels with different characteristics. The left ventricle has a thicker layer of muscle around it, a necessary adaptation for powering its beat against the high resistance of the extensive systemic circulation throughout the body. The right ventricle has a thinner wall, consistent with its role in pumping blood to the lungs against a much lower resistance.

EMBRYONIC DEVELOPMENT OF THE CIRCULATORY SYSTEM

An embryo develops only with an adequate supply of oxygen and metabolites. In its early stages these may be provided by diffusion. Because the rate of diffusion becomes limiting beyond a certain size, however, the circulatory system becomes functional early in development, often before other organs and systems are obvious.

The heart develops from the middle embryonic tissue layer, the mesoderm, just below the anterior part of the gut. It begins as a tube that joins with blood vessels also forming in the mesoderm. Other mesodermal cells form a coat around the heart tube and become the muscular wall, or myocardium. The heart lies in its own section of body cavity, called the pericardial coelom, formed by partitions that cut it off from the main body cavity. From an original tube shape, the heart bends back on itself as it grows within the pericardial cavity. The sinus venosus and atrium lie above the ventricle and bulbus cordis (embryonic equivalent of the conus arteriosus). Septa gradually partition the heart into chambers.

In mammalian and bird embryos, the lungs are not used until birth. Oxygen is obtained in the former from the placenta and in the latter from embryonic membranes close to the porous eggshell.

The circulation has various modifications for diverting oxygenated blood from sources outside the embryo to the body of the embryo. In mammals blood from the placenta travels to the right auricle via the umbilical vein and posterior vena cava. It passes through an opening, the foramen ovale, into the left auricle, and then to the left ventricle and around the body. Deoxygenated blood entering the anterior vena cava fills the right ventricle; however, instead of passing to the lungs, it is shunted through the ductus arteriosus, between the pulmonary and systemic arches, and into the dorsal aorta. From the dorsal aorta the deoxygenated blood travels to the placenta, bypassing the lungs completely. At birth the foramen ovale closes, as does the ductus arteriosus, and the lungs become functional.

The development of the circulatory system in higher vertebrate embryos (*i.e.*, those of birds and mammals) generally follows a sequence of seven main events. Initially, a tubular heart bends into an "S" shape. Blood then flows from behind forward through the sinus venosus, atrium, ventricle, and bulbus cordis. There is then subdivision of the atrium and ventricle and of the opening between

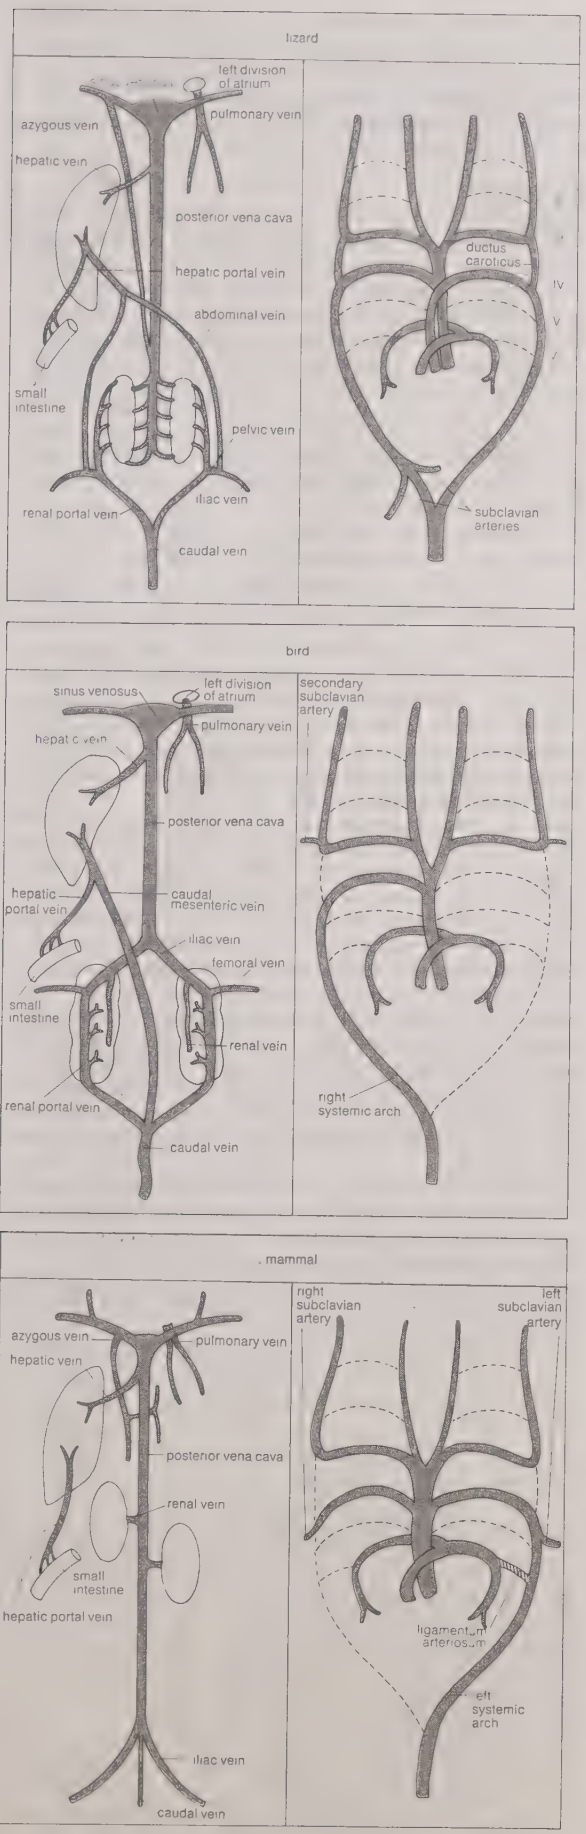

Figure 7: Vascular systems of the vertebrates lizard, bird, and mammal, showing (at left) the venous system and (at right) the arterial system as seen in ventral views.

them. The sinus venosus is incorporated into the right atrium. The pulmonary veins are segregated to open into the left atrium. The bulbus cordis is subdivided into a pulmonary trunk from the right ventricle and a systemic trunk from the left ventricle. Finally, an embryonic set of six arterial arches is reduced to three in adults, and their relationships are further complicated by asymmetrical loss of some parts and development of others.

BIODYNAMICS OF VERTEBRATE CIRCULATION

Blood pressure and blood flow. The pressure that develops within the closed vertebrate circulatory system is highest at the pump—the heart—and decreases with distance away from the pump because of friction within the blood vessels. Because the blood vessels can change their diameter, blood pressure can be affected by both the action of the heart and changes in the size of the peripheral blood vessels. Blood is a living fluid—it is viscous and contains cells (45 percent of its volume in human beings)—and yet the effects of the cells on its flow patterns are small.

Blood enters the atrium by positive pressure from the venous system or by negative pressure drawing it in by suction. Both mechanisms operate in vertebrates. Muscular movements of the limbs and body, and gravity in land vertebrates, are forces propelling blood to the heart. In fishes and amphibians the atrium forces blood into the ventricle when it contracts. In birds and mammals the blood arrives at the heart with considerable residual pressure and passes through the auricles into the ventricles, apparently without much additional impetus from contraction of the auricles.

Two pressure levels

The ventricle is the main pumping chamber, but one of the features of double circulation is that the two circuits require different pressure levels. Although the shorter pulmonary circulation requires less pressure than the much longer systemic circuit, the two are connected to each other and must transport the same volume of fluid per unit time. The right and left ventricles in birds and mammals function as a volume and a pressure pump, respectively. The thick muscular wall of the left ventricle ensures that it develops a higher pressure during contraction in order to force blood through the body. It follows that pressures in the aorta and pulmonary artery may be very different. In human beings aortic pressure is about six times higher.

Valves throughout the system are crucial to maintain pressure. They prevent backflow at all levels; for example, they prevent flow from the arteries back into the heart as ventricular pressure drops at the end of a contraction cycle. Valves are important in veins, where the pressure is lower than in arteries.

Another impetus to blood flow is contraction of the muscles in the walls of vessels. This also prevents backflow of arterial blood toward the heart at the end of each contraction cycle. Input from nerves, sensory receptors in the vessels themselves, and hormones all influence blood vessel diameter, but responses differ according to position in the body and animal species.

Normally, the pressures that develop in a circulatory system vary widely in different animals. Body size can be an important factor. The closed circulation systems of vertebrates generally operate at higher pressures than the open blood systems of invertebrates; the systems of birds and mammals operate at the highest pressures of all.

Electrical activity. The vertebrate heart is myogenic (rhythmic contractions are an intrinsic property of the cardiac muscle cells themselves). Pulse rate varies widely in different vertebrates, but it is generally higher in small animals, at least in birds and mammals. Each chamber of the heart has its own contraction rate. In the frog, for example, the sinus venosus contracts fastest and is the pacemaker for the other chambers, which contract in sequence and at a decreasing rate, the conus being the slowest. In birds and mammals, where the sinus venosus is incorporated into the right atrium at the sinoauricular node, the latter is still the pacemaker and the heartbeat is initiated at that point. Thus, the evolutionary history of the heart explains the asymmetrical pattern of the heartbeat.

In the frog each contraction of the heart begins with a localized negative charge that spreads over the surface of

the sinus venosus. In lower vertebrates, the cardiac muscle cells themselves conduct the wave of excitation. In birds and mammals, however, special conducting fibres (arising from modified muscle cells) transmit the wave of excitation from the sinoauricular node to the septum between the auricles, and then, after a slight delay, down between and around the ventricles. The electrical activity of the heart can be recorded; the resulting pattern is called an electrocardiogram.

Factors

Control of heartbeat and circulation. Many factors, such as temperature, oxygen supply, or nervous excitement, affect heartbeat and circulation. Blood circulation is controlled mainly via nerve connections, sensory receptors, and hormones. These act primarily by varying the heart's pulse rate, amplitude, or stroke volume and by altering the degree of dilation or constriction of the peripheral blood vessels (*i.e.*, those blood vessels near the surface of the body).

Temperature has a direct effect on heart rate, and one of the ways in which mammals regulate their internal temperature is by controlling peripheral blood circulation. Mammals are endothermic (warm-blooded) vertebrates; their internal temperature is kept within narrow limits by using heat generated by the body's own metabolic processes. Lizards are ectothermic (cold-blooded); they obtain heat from the external environment by, for example, basking in the sun. The effects of oxygen concentration on the heart and blood vessels is rapid. Oxygen deficiency in the cardiac tissue causes dilation of the coronary capillaries, thereby increasing blood flow and oxygen supply.

Most effects on the circulation are indirect and complex. All vertebrate hearts receive input from nerves; for example, stimulation of a branch of the vagus nerve causes the release of acetylcholine at the nerve endings, which depresses the heart rate. Other nerve endings release norepinephrine, which increases the heart rate. Less directly, nervous stimulation brought about by stress causes the release of the hormones epinephrine and norepinephrine into the bloodstream. These substances not only make the heart beat faster and with a greater amplitude, but they also divert blood to the muscles by constricting the vessels in the skin and gut. This prepares the animal physiologically for physical exertion. Numerous other chemicals, such as nicotine, affect heart rate directly or indirectly.

Two other factors are important in the context of circulatory regulation—the concentrations of inorganic ions and sensory receptors in blood vessel walls. Sodium, potassium, and calcium ions are always involved in changes of electrical potential across cell membranes. A change in their concentrations, therefore, influences heartbeat profoundly. External calcium concentration can, for example, determine the conductance of sodium across the cardiac cell membranes. Sensory receptors in the walls of blood vessels register blood pressure. They are found in the aorta, carotid arteries, pulmonary artery, capillaries in the adrenal gland, and the tissues of the heart itself. Impulses from the receptors travel to the medulla of the brain, from where messages are sent via motor nerves to the heart and blood vessels. Regulation is thus achieved according to the body's needs. (M.E.Ro.)

The human cardiovascular system

The human cardiovascular system is a closed tubular system in which blood, propelled by a muscular heart, flows through vessels to and from all parts of the body. Two circuits, the pulmonary and the systemic, consist of arterial, capillary, and venous components.

The primary function of the heart is to serve as a muscular pump propelling blood into and through vessels to and from all parts of the body. The arteries, which receive this blood at high pressure and velocity and conduct it throughout the body, are thickly walled with elastic fibrous tissue and muscle cells. The arterial tree—the branching system of arteries—terminates in short, narrow, muscular vessels called arterioles, from which blood enters simple endothelial tubes (*i.e.*, tubes formed of endothelial, or lining, cells) known as capillaries. These microscopically thin capillaries are permeable to vital cellular nutrients and waste products and distribute and receive nutrients and wastes. From the capillaries, the blood, now depleted of oxygen and burdened with waste products, moving more slowly and under low pressure, enters small vessels called venules, which converge to form veins, ultimately guiding the blood on its way back to the heart.

THE HEART

Description. *Shape and location.* The human adult heart is normally slightly larger than a clenched fist with average dimensions of about $13 \times 9 \times 6$ centimetres ($5 \times 3\frac{1}{2} \times 2\frac{1}{2}$ inches) and weighing approximately 10.5 ounces (300 grams). It is cone-shaped in appearance, with the broad base directed upward and to the right and the apex pointing downward and to the left. It is located in the chest (thoracic) cavity behind the breastbone, or sternum in front of the windpipe, or trachea, the esophagus, and the descending aorta, between the lungs, and above the diaphragm (the muscular partition between the chest and abdominal cavities). About two-thirds of the heart lies to the left of the midline.

Fibrous pericardium

Pericardium. The heart is suspended in its own membranous sac, the pericardium. The strong outer portion of the sac, or fibrous pericardium, is firmly attached to the diaphragm below, the mediastinal pleura on the side, and the sternum in front, and gradually blends with the coverings of the superior vena cava and the pulmonary (lung) arteries and veins leading to and from the heart. (The space between the two lungs, the mediastinum, is bordered by the mediastinal pleura, a continuation of the membrane lining the chest. The superior vena cava is the principal channel for venous blood from the chest, the arms, the neck, and the head.)

Smooth, serous (moisture-exuding) membrane lines the fibrous pericardium, then bends back and covers the heart (Figure 8). The portion of membrane lining the fibrous pericardium is known as the parietal serous layer, or parietal pericardium, that covering the heart as the visceral serous layer, visceral pericardium, or epicardium.

The two layers of serous membrane are normally separated only by 10 to 15 millilitres (0.6 to 0.9 cubic inch) of pericardial fluid, which is secreted by the serous membranes. The slight space created by the separation is called the pericardial cavity. The pericardial fluid lubricates the two membranes with every beat of the heart as their surfaces glide over each other. Fluid is filtered into the pericardial space through both the visceral and parietal pericardia.

Chambers of the heart. The heart is divided by septa, or partitions, into right and left halves, and each half is subdivided into two chambers. The upper chambers, the atria, are separated by a partition known as the interatrial septum; the lower chambers, the ventricles, are separated by the interventricular septum (Figure 9). The atria re-

ceive blood from various parts of the body and pass it into the ventricles. The ventricles, in turn, pump blood to the lungs and to the remainder of the body.

The right atrium, or right superior portion of the heart, is a thin-walled chamber receiving blood from all tissues except the lungs. Three veins empty into the right atrium, the superior and inferior venae cavae, bringing blood from the upper and lower portions of the body, respectively, and the coronary sinus, draining blood from the heart itself. Blood flows from the right atrium to the right ventricle. The right ventricle, the right inferior portion of the heart, is the chamber from which the pulmonary artery carries blood to the lungs.

The left atrium, the left superior portion of the heart, is slightly smaller than the right atrium and has a thicker wall. The left atrium receives the four pulmonary veins, which bring oxygenated blood from the lungs. Blood flows from the left atrium into the left ventricle. The left ventricle, the left inferior portion of the heart, has walls three times as thick as those of the right ventricle. Blood is forced from this chamber through the aorta to all parts of the body except the lungs.

Interventricular sulci

External surface of the heart. Shallow grooves called the interventricular sulci, containing blood vessels, mark the separation between ventricles on the front and back surfaces of the heart. There are two grooves on the external surface of the heart. One, the atrioventricular groove, is along the line where the right atrium and the right ventricle meet; it contains a branch of the right coronary artery (the coronary arteries deliver blood to the heart muscle). The other, the anterior interventricular sulcus, runs along the line between the right and left ventricles and contains a branch of the left coronary artery.

On the posterior side of the heart surface, a groove called the posterior longitudinal sulcus marks the division between the right and left ventricles; it contains another branch of a coronary artery. A fourth groove, between the left atrium and ventricle, holds the coronary sinus, a channel for venous blood.

Origin and development. In the embryo, formation of the heart begins in the pharyngeal, or throat, region. The first visible indication of the embryonic heart occurs in the undifferentiated mesoderm, the middle of the three primary layers in the embryo, as a thickening of invading cells. An endocardial (lining) tube of flattened cells subsequently forms and continues to differentiate until a young tube with forked anterior and posterior ends arises.

Primary chambers in embryo

As differentiation and growth progress, this primitive tube begins to fold upon itself, and constrictions along its length produce four primary chambers. These are called, from posterior to anterior, the sinus venosus, atrium, ventricle, and truncus arteriosus (Figure 10). The characteristic bending of the tube causes the ventricle to swing first to the right and then behind the atrium, the truncus coming to lie between the sideways dilations of the atrium. It is during this stage of development and growth that the first pulsations of heart activity begin.

Endocardial cushions (local thickenings of the endocardium, or heart lining) "pinch" the single opening between the atrium and the ventricle into two portions, thereby forming two openings. These cushions are also responsible for the formation of the two atrioventricular valves (the valves between atria and ventricles), which regulate the direction of blood flow through the heart.

The atrium becomes separated into right and left halves first by a primary partition with a perforation and later by a secondary partition, which, too, has a large opening, called the foramen ovale, in its lower part. Even though the two openings do not quite coincide in position, blood still passes through, from the right atrium to the left. At birth, increased blood pressure in the left atrium forces the primary partition against the secondary one, so that the two openings are blocked and the atria are completely separated. The two partitions eventually fuse.

The ventricle becomes partially divided into two chambers by an indentation of myocardium (heart muscle) at its tip. This developing partition is largely muscular and is supplemented by membranous connective tissue that develops in conjunction with the subdivision of the truncus arteriosus by a spiral partition into two channels, one for systemic and one for pulmonary circulation (the aorta and the pulmonary artery, respectively). The greater portion of blood passing through the right side of the heart in the fetus is returned to the systemic circulation by the ductus arteriosus, a vessel connecting the pulmonary artery and the aorta. At birth this duct becomes closed by a violent contraction of its muscular wall. Thereafter the blood in the right side of the heart is driven through the pulmonary arteries to the lungs for oxygenation and returned to the left side of the heart for ejection into the systemic circulation. A distinct median furrow at the apex of the ventricles marks the external subdivision of the ventricle into right and left chambers.

Structure and function. *Valves of the heart.* To prevent backflow of blood, the heart is equipped with valves that permit the blood to flow in only one direction (Figure 11). There are two types of valves located in the heart: the atrioventricular valves (tricuspid and mitral) and the semilunar valves (pulmonary and aortic).

The atrioventricular valves are thin, leaflike structures located between the atria and the ventricles. The right atrioventricular opening is guarded by the tricuspid valve,

so called because it consists of three irregularly shaped cusps, or flaps. The leaflets consist essentially of folds of endocardium (the membrane lining the heart) reinforced with a flat sheet of dense connective tissue. At the base of the leaflets, the middle supporting flat plate becomes continuous with that of the dense connective tissue of the ridge surrounding the openings.

Chordae tendineae and papillary muscles

Tendinous cords of dense tissue (chordae tendineae) covered by thin endocardium extend from the nipplelike papillary muscles to connect with the ventricular surface of the middle supporting layer of each leaflet. The chordae tendineae and the papillary muscles from which they arise limit the extent to which the portions of the valves near their free margin can billow toward the atria. The left atrioventricular opening is guarded by the mitral, or bicuspid, valve, so named because it consists of two flaps. The mitral valve is attached in the same manner as the tricuspid, but it is stronger and thicker because the left ventricle is by nature a more powerful pump working under high pressure.

Blood is propelled through the tricuspid and mitral valves as the atria contract. When the ventricles contract, blood is forced backward, passing between the flaps and walls of the ventricles. The flaps are thus pushed upward until they meet and unite, forming a complete partition between the atria and the ventricles. The expanded flaps of the valves are restrained by the chordae tendineae and papillary muscles from opening into the atria.

The semilunar valves are pocketlike structures attached at the point at which the pulmonary artery and the aorta leave the ventricles. The pulmonary valve guards the orifice between the right ventricle and the pulmonary artery. The aortic valve protects the orifice between the left ventricle and the aorta. The three leaflets of the aortic semilunar and two leaflets of the pulmonary valves are thinner than those of the atrioventricular valves, but they are of the same general construction with the exception that they possess no chordae tendineae.

Closure of the heart valves is associated with an audible sound. The first sound occurs when the mitral and tricuspid valves close, the second when the pulmonary and aortic semilunar valves close. These characteristic heart sounds have been found to be caused by the vibration of the walls of the heart and major vessels around the heart. The first heart sound, or "lubb," is heard when the ventricles contract, causing a sudden backflow of blood that closes the valves and causes them to bulge back. The elasticity of the valves then causes the blood to bounce backward into each respective ventricle. This effect sets the walls of the ventricles into vibration, and the vibrations travel away from the valves. When the vibrations reach the chest wall where the wall is in contact with the heart, sound waves are created that can be heard with the aid of a stethoscope.

The second heart sound results from vibrations set up in the walls of the pulmonary artery, the aorta, and, to a lesser extent, the ventricles as the blood reverberates back and forth between the walls of the arteries and the valves after the pulmonary and aortic semilunar valves suddenly close. These vibrations are then heard as the "dupp" sound as the chest wall transforms the vibrations into sound waves. The first heart sound is followed after a short pause by the second. A pause about twice as long comes between the second sound and the beginning of the next cycle. The opening of the valves is silent.

Wall of the heart. The wall of the heart consists of three distinct layers—the epicardium (outer layer), the myocardium (middle layer), and the endocardium (inner layer). Coronary vessels supplying arterial blood to the heart penetrate the epicardium before entering the myocardium. This outer layer, or visceral pericardium, consists of a surface of flattened epithelial (covering) cells resting upon connective tissue.

Three layers of the heart wall

The myocardium consists of interlacing bundles of cardiac muscle fibres (Figure 12) possessing the appearance of striated muscle (striped skeletal muscle) with intermittent dark plates crossing the fibres, but these highly specialized fibres differ fundamentally from those of skeletal muscle in the arrangement of nuclei and in the smaller calibre of the individual fibre. The nuclei are oval and situated along the central axis of the fibre, which may range in size from 12 to 21 micrometres in diameter. Each fibre consists of a bundle of smaller fibres, called myofibrils, each of which passes through the full length of the fibre and is covered by an external limiting membrane known as the sarcolemma.

From S. Jacob and C. Francone, *Structure and Function in Man* (1970); W.B. Saunders Co.

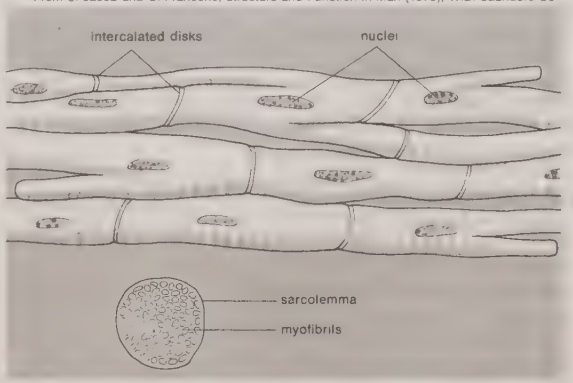

Figure 12: Cardiac muscle.

The individual cardiac muscle cells are striped crosswise throughout, with alternating dark bands that are opaque to light and with light bands that permit the passage of light. Prominent plates of condensed dark bands called intercalated disks, crossing the muscle fibre at uneven intervals, are perhaps the most conspicuous features unique to cardiac muscle.

It is the myocardial layer that causes the heart to contract; the bundles of the muscle fibres are so arranged as to result in a wringing type of movement that efficiently squeezes blood from the heart with each beat (Figure 13). The thickness of the myocardium varies according to the pressure generated to move blood to its destination. The myocardium of the left ventricle, which must drive blood out into the systemic circulation, is, therefore, thickest; the myocardium of the right ventricle, which propels blood to the lungs, is moderately thickened, while the atrial walls are relatively thin.

Forming the inner surface of the myocardial wall is a thin lining called the endocardium. This layer lines the

cavities of the heart, covers the valves and small muscles associated with opening and closing of the valves, and is continuous with the lining membrane of the large blood vessels. (S.W.J./Ed.)

Blood supply to the heart. Because of the watertight lining of the heart (the endocardium) and the thickness of the myocardium, the heart cannot depend on the blood contained in its own chambers for oxygen and nourishment. It possesses a vascular system of its own, called the coronary arterial system. In the most common distribution, this comprises two major coronary arteries, the right and the left; normally, the left coronary artery divides soon after its origin into two major branches, called the left anterior descending and the circumflex coronary arteries. The right, the left anterior descending, and the left circumflex coronary arteries have many branches and are of almost equal importance. Thus, there are commonly said to be three main functional coronary arteries rather than two.

The right and left coronary arteries originate from the right and left aortic sinuses (the sinuses of Valsalva), which are bulges at the origin of the ascending aorta immediately beyond, or distal to, the aortic valve. The ostium, or opening, of the right coronary artery is in the right aortic sinus and that of the left coronary artery is in the left aortic sinus, just above the aortic valve ring. There is also a non-coronary sinus of Valsalva, which lies to the left and posteriorly at the origin of the ascending aorta. The left coronary arterial system is more important than the right because it supplies blood to the larger left ventricle, and the dimension of the left coronary ostium is larger than that of the right.

The right coronary artery has a lumen diameter of about 2.5 millimetres or more. It supplies the right ventricular outflow tract, the sinoatrial node (the principal pacemaker of the heart), the atrioventricular node, and the bulk of the right ventricle, with branches extending into the interventricular septum and joining with arteriolar branches from the left coronary artery more or less where the two ventricles join.

The left coronary artery

The main stem of the left coronary artery has a luminal diameter often exceeding 4.5 millimetres and is one of the shortest and most important vessels of the body. Usually, it is between one and two centimetres in length, but it may have a length of only two millimetres before dividing. Sometimes the main left coronary artery may actually be missing, with the left coronary ostium having two separate openings for the left anterior descending and the left circumflex arteries. The main left coronary artery divides into its two branches, the anterior descending and the circumflex, while still in the space between the aorta and pulmonary artery. The left anterior descending coronary artery usually begins as a continuation of the left main coronary artery, and its size, length, and distribution are key factors in the balance of the supply of blood to the left ventricle and the interventricular septum. There are many branches of the left anterior descending artery; the first and usually the largest septal branch is important because of its prominent role in supplying blood to the septum.

The left circumflex artery leaves the left main coronary artery to run posteriorly along the atrioventricular groove. It divides soon after its origin into an atrial branch and an obtuse marginal branch. The former branch sometimes has a branch to the sinoatrial node (more usually supplied from the right coronary artery). The obtuse marginal vessel supplies the posterior left ventricular wall in the direction of the apex.

Venous circulation

Venous blood from the heart is carried through veins, which usually accompany the distribution of the distal arteries. These cardiac veins, however, proceed into the atrioventricular grooves anteriorly and posteriorly to form the coronary venous sinus, which opens into the right ventricle immediately below the tricuspid valve.

In addition to these identifiable anatomic arterial and venous channels, nutritional exchange almost certainly takes place between the endocardial ventricular muscle layers and the blood in the cavity of the ventricles. This is of minor importance and probably is an adaptive system in situations of cardiac muscle pathology. (M.F.O.)

Heartbeat. *Regulation of heartbeat.* Regular beating of the heart is achieved as a result of the inherent rhythmicity of cardiac muscle; no nerves are located within the heart itself, and no outside regulatory mechanisms are necessary to stimulate the muscle to contract rhythmically. That these rhythmic contractions originate in the cardiac muscle can be substantiated by observing cardiac development in the embryo; cardiac pulsations begin before adequate development of nerve fibres. In addition, it can be demonstrated in the laboratory that even fragments of cardiac muscle in tissue culture continue to contract rhythmically. Furthermore, there is no gradation in degree of contraction of the muscle fibres of the heart, as would be expected if they were primarily under nervous control.

The mere possession of this intrinsic ability is not sufficient, however, to enable the heart to function efficiently. Proper function requires coordination, which is maintained by an elaborate conducting system within the heart that consists primarily of two small, specialized masses of tissue, or nodes, from which impulses originate and of nervelike conduits for the transmission of impulses, with terminal branches extending to the inner surface of the ventricles.

A basic understanding of the method by which an impulse is transmitted is essential before the conduction system that exists within the heart can be properly understood. Electrical potentials exist across membranes of essentially all cells of the body—that is, there is an electrical potential gradient created, generally by an excess of negative ions immediately inside the cell membrane and an equal excess of positive ions on the outside of the membrane, also known as a resting potential. (Ions are atoms or groups of atoms in solution that carry positive or negative electrical charges.) Further, some cells, such as nerve and muscle cells, have the additional distinction of being "excitable"—*i.e.,* capable of conducting impulses along their membranes.

Any factor that suddenly increases the permeability of the cell membrane and allows positive ions to flow through the membrane to the inside, while negative ions flow to the outside, is likely to bring about a sequence of rapid changes in the membrane potential, lasting only a fraction of a second. This change is followed by the return of the membrane potential to its resting value. This sequence of changes in potential is called an action potential and is responsible for the initiation of impulses transmitted, in the case of the heart, along the muscle fibres and the special conducting tissue fibres. Electrical stimulation, application of chemicals, mechanical damage, heat, and cold are among the factors that can bring about a change in the state of a cell membrane, momentarily disturbing its normal resting state and creating an action potential.

Action potential

The action potential occurs in two separate stages called depolarization and repolarization. During the process of depolarization, the normal negative potential inside the muscle fibre is lost, and the membrane potential actually reverses, or becomes slightly positive inside and negative outside the membrane. This process proceeds as a wave along the length of the muscle fibres. It lasts only a fraction of a second before the positive ions begin to resume

their original position on the outside of the membrane, necessary before another impulse can pass. This recovery process is termed repolarization. An action potential is necessary to generate each depolarization wave.

The sinoatrial node (Figure 14) possesses the ability to generate an action potential spontaneously. This highly important structure is a small strip of specialized muscle located in the posterior wall of the right atrium, immediately beneath the point of entry of the superior vena cava. After each action potential is generated in the sinoatrial node, the impulse immediately spreads through the atrial muscle in the form of a ripple pattern similar to the pattern of waves generated when a stone is thrown into a pool of water.

From S. Jacob and C. Francone, *Structure and Function in Man* (1970). W.B. Saunders Co.

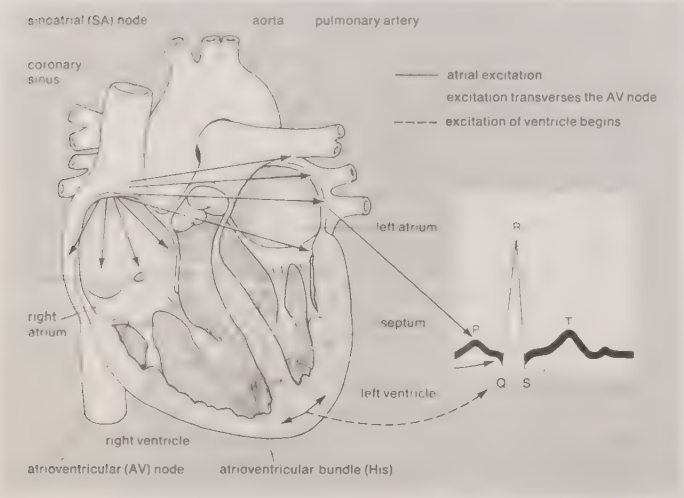

Figure 14: Conducting system of the heart showing source of electrical impulses produced on electrocardiogram.

A few specialized atrial fibres relay this potential, or impulse, to the atrioventricular node, located in the lower part of the right rear atrial wall. To permit sufficient time for complete contraction of the atria before subsequent simultaneous contraction of the ventricles, the impulse is delayed slightly in its passage through the atrioventricular node. The special conducting fibres that leave this node form the bundle of His, which terminates in the multiple branches of the Purkinje network in the left and right ventricles. (The bundle of His was named for the German cardiologist Wilhelm His, Jr., who described it in 1893.) The bundle of His passes between the atrioventricular valves and leads into the interventricular septum, where bundles of fibres in right and left branches project downward beneath the endocardium on either side of the septum. They then curve around the tip of the ventricles and back toward the atria along the side walls.

Conducting system of the heart. Both the atrioventricular node, with an intrinsic beat of 40–60 beats per minute, and the Purkinje fibres, with an intrinsic beat of 15–40 beats per minute, are self-stimulating and capable of rhythmic contraction, but at a rate slower than that of the sinoatrial node, which possesses an intrinsic capacity to beat 72 times per minute. Therefore, since recovery time is faster in the sinoatrial node, it controls the rate of the heartbeat, serving as the primary pacemaker. The atrioventricular node, with its 40–60 beats per minute, is termed the secondary pacemaker.

Effect of ions on heart function. Potassium, sodium, and calcium have a marked influence on transmission of action potentials within cardiac muscle. In addition, calcium-ion concentration is important in the contractile process. The concentration of ions in extracellular fluids (those outside the cells) also affects cardiac function to a degree.

Excess ions

Excess potassium ions in extracellular fluid can slow the heart rate and cause the heart to dilate and become flaccid (flabby). There is general weakness of cardiac muscle. This weakening of the strength of contraction is caused by a decreased resting membrane potential with resulting decrease in the intensity of the action potential. Calcium ions in excess produce just the opposite effect; the heart goes into spastic contraction. There is, however, little danger of the presence of excess calcium ions within the extracellular fluid in cardiac muscle, for excess calcium is precipitated as salts in the body tissues before a dangerous level is reached in the heart. A depressed cardiac function occurs when sodium ions are present in excess. These ions interfere with the effectiveness of calcium in bringing about normal muscular contraction.

Presumably because of an increased permeability of muscle membrane to ions, temperature may also affect heart function. An increased heart rate occurs as temperature increases, and, conversely, heart rate decreases with decreased temperature.

Electrocardiogram. As an impulse travels along the cardiac muscle fibres, an electric current is generated by the flowing ions. This current spreads into the fluids around the heart, and a minute portion actually flows to the surface of the body. An electrocardiogram is a record of this electrical activity (Figure 14) as measured by a device called a galvanometer. Leads (*i.e.*, wires to the galvanometer) are placed on the surface of the body at various points, depending on the type of information desired. An electrocardiogram thus has the prime function of assessing the ability of the heart to transmit the cardiac impulse. Each portion of the cardiac cycle produces a different electrical impulse, causing the characteristic deflections of an electrocardiographic recording needle. The deflections, or waves, on the recording apparatus are, in order, the P, QRS complex, and T waves.

As a wave of depolarization passes over the atria, the impulse is recorded as the P wave. As it continues on through the ventricles, it is registered as the QRS complex. The T wave is caused by currents generated as the ventricles recover from the state of depolarization. This repolarization process occurs in the muscle of the ventricles about 0.25 second after depolarization. There are, therefore, both depolarization and repolarization waves represented in the electrocardiogram. The atria repolarize at the same time that the ventricles depolarize. The atrial repolarization wave is, however, obscured by the larger QRS wave.

Nervous control of the heart. Nervous control of the heart is maintained by the parasympathetic fibres in the vagus nerve (parasympathetic) and by the sympathetic nerves. The vagus nerve is the cardiac inhibitor, and the sympathetic nerves are the cardiac excitors. Stimulation of the vagus nerve depresses the rate of impulse formation and atrial contractility and thereby reduces cardiac output and slows the rate of the heart. Parasympathetic stimulation can also produce varying degrees of impaired impulse formation or heart block in diseases of the heart. (In complete heart block the atria and the ventricles beat independently.) Stimulation of the sympathetic nerves increases contractility of both atria and ventricles.

Diastole and systole

The cardiac cycle is defined as that time from the end of one heart contraction to the end of the subsequent contraction and consists of a period of relaxation called diastole followed by a period of contraction called systole. During the entire cycle, pressure is maintained in the arteries; however, this pressure varies during the two periods, the normal diastolic pressure being 80 millimetres of mercury and the normal systolic pressure being 120 millimetres of mercury.

Blood-pressure regulation and measurement. Changes in blood pressure may depend on several regulating mechanisms. Arterioles present the main resistance to blood flow. Blood pressure, therefore, can be maintained only if resistance in these arterioles falls each time cardiac output increases. The nerves that control the action of the small muscle fibres of the vessels maintain resistance at a level sufficient for high arterial blood pressure by constricting the channel, or lumen, of the arteriole; during dilation of the vessel, pressure is decreased. Arterial pressure is also affected by the chemical composition of the blood. A decreased oxygen or increased carbon dioxide tension (partial pressure) causes a reflex elevation of blood pressure. Respiratory activity is, therefore, an important regulator of arterial pressure.

The renin–angiotensin system provides hormonal control

of blood pressure. Decreased blood flow to the kidney, changes in posture, or blockage of one or both renal (kidney) arteries may lead to increased production of the enzyme renin by the kidney. This substance causes development in the circulating blood of the substance angiotensin II, which causes blood vessels to contract, with resultant increase in blood pressure.

Receptors in great veins, in the aortic arch (the bend in the aorta above the heart), and the carotid sinus are sensitive to changes in blood pressure as blood is forced from the ventricles. These receptors, known as baroreceptors, help to modify shifts in pressure. When the receptors are stimulated by a rise in arterial pressure, which distends the arterial wall, reflexes are initiated that have an inhibiting effect on the heart, causing it to beat more slowly and with less force. At the same time there is a decrease in the constriction of the blood vessels. A fall in pressure, on the other hand, causes increased sympathetic and decreased parasympathetic nervous stimulation, with resultant increased heart rate and also a subsequent constriction of the blood vessels.

Force of cardiac contraction

The force of the heartbeat depends on the initial length of the heart muscle fibres, the length of the pause in diastole, the oxygen supply, and the integrity and mass of the heart muscle, or myocardium. The greater the initial length of the muscle fibres in the heart, the more forceful will be the contraction. Artificially increasing venous return of blood to the heart distends the heart and intensifies the force of the beat. The greater inflow is handled by an increased output of the heart, without a change in its rate. When the ventricle does not completely fill (for example, after loss of blood), the force of the heartbeat is reduced. When the venous inflow during diastole is increased, as in muscular exercise, the beats become more forceful. If, as a result of excessive filling, the fibres are overstretched, a weak contraction results, with diminished cardiac output; consequently, the heart does not adequately empty itself. The force of the heart is also diminished if the diastolic phase is too short and there is inadequate filling.

Blood pressure is measured with a device called a sphygmomanometer. The pressure of blood within the artery is balanced by an external pressure exerted by air contained in a cuff applied externally around the arm. Actually, it is the pressure within the cuff that is measured. The steps employed in determining blood pressure with a sphygmomanometer are:

1. The cuff is wrapped securely around the arm above the elbow.
2. Air is pumped into the cuff with a rubber bulb until pressure is sufficient to stop the flow of blood in the brachial artery (the principal artery of the upper arm). Pressure within the cuff is shown on the scale of the sphygmomanometer.
3. The observer places a stethoscope over the brachial artery just below the elbow and gradually releases the air from within the cuff. The decreased air pressure permits the blood to flow, filling the artery below the cuff. Faint tapping sounds corresponding to the heartbeat are heard. When the sound is first noted, the air pressure within the cuff is recorded on the scale. This pressure is equal to the systolic blood pressure.
4. As the air in the cuff is further released, the sounds become progressively louder, until the sounds change in quality from loud to soft and finally disappear. The point at which the sound completely disappears should be recorded as diastolic blood pressure.

THE BLOOD VESSELS

Because of the need for the early development of a transport system within the embryo, the organs of the vascular system are among the first to appear and to assume their functional role. In fact, this system is established in its basic form by the fourth week of embryonic life. At approximately the 18th day of gestation, cells begin to group together between the outer skin (ectoderm) and the inner skin (endoderm) of the embryo. These cells soon become rearranged so that the more peripheral ones join to form a continuous flattened sheet enclosing more centrally placed cells; these cells remain suspended in a fluid medium as primitive blood cells. The tubes then expand and unite to form a network; the primitive blood vessels thus appear.

The blood vessels consist of a closed system of tubes that transport blood to all parts of the body and back to the heart. As in any biologic system, structure and function of the vessels are so closely related that one cannot be discussed without the other's being taken into account.

Arteries transport blood to body tissues under high pressure, which is exerted by the pumping action of the heart. The heart forces blood into these elastic tubes, which recoil, sending blood on in pulsating waves. It is, therefore, imperative that the vessels possess strong, elastic walls to ensure fast, efficient blood flow to the tissues.

Three layers of the artery wall

The wall of an artery consists of three layers (Figures 15 and 16), the innermost consisting of an inner surface of smooth endothelium covered by a surface of elastic tissues: the two form the tunica intima. The tunica media, or middle coat, is thicker in arteries, particularly in the large arteries, and consists of smooth muscle cells intermingled with elastic fibres. The muscle-cell and elastic fibres circle the vessel. In larger vessels the tunica media is composed primarily of elastic fibres. As arteries become smaller, the number of elastic fibres decreases while the number of smooth muscle fibres increases. The outer layer, the tunica adventitia, is the strongest of the three layers. It is composed of collagenous and elastic fibres. (Collagen is a connective-tissue protein.) The tunica adventitia provides a limiting barrier, protecting the vessel from overexpansion. Also characteristic of this layer is the presence of

From S. Jacob and C. Francone, *Structure and Function in Man* (1970) W.B. Saunders Co.

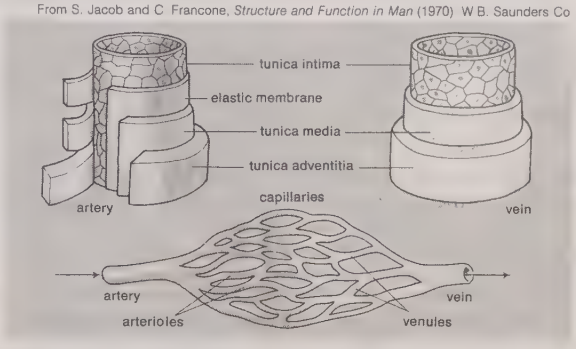

Figure 15: Component parts of arteries and veins.

small blood vessels called the vasa vasorum that supply the walls of larger arteries and veins; the inner and middle layers are nourished by diffusion from the blood as it is transported. The thicker, more elastic wall of arteries enables them to expand with the pulse and to regain their original size.

The transition from artery to arteriole is a gradual one, marked by a progressive thinning of the vessel wall and a decrease in the size of the lumen, or passageway. The tunica intima is still present as a lining covered by a layer of thin longitudinal fibres. A single layer of circular or spiral smooth muscle fibres now makes up the tunica media, and the tunica adventitia consists of connective tissue elements.

Being the last small branches of the arterial system, arterioles must act as control valves through which blood is released into the capillaries. The strong muscular wall of arterioles is capable of completely closing the passageway or permitting it to expand to several times its normal size, thereby vastly altering blood flow to the capillaries. Blood flow is by this device directed to tissues that require it most.

As the arterioles become smaller in size, the three coats become less and less definite, the smallest arterioles consisting of little more than endothelium, or lining, surrounded by a layer of smooth muscle. The microscopic capillary tubules consist of a single layer of endothelium, a continuation of the innermost lining cells of arteries and veins.

As the capillaries converge, small venules are formed whose function it is to collect blood from the capillary beds (*i.e.*, the networks of capillaries). The venules consist of an endothelial tube supported by a small amount of collagenous tissue and, in the larger venules, by a few smooth muscle fibres as well. As venules continue to increase in

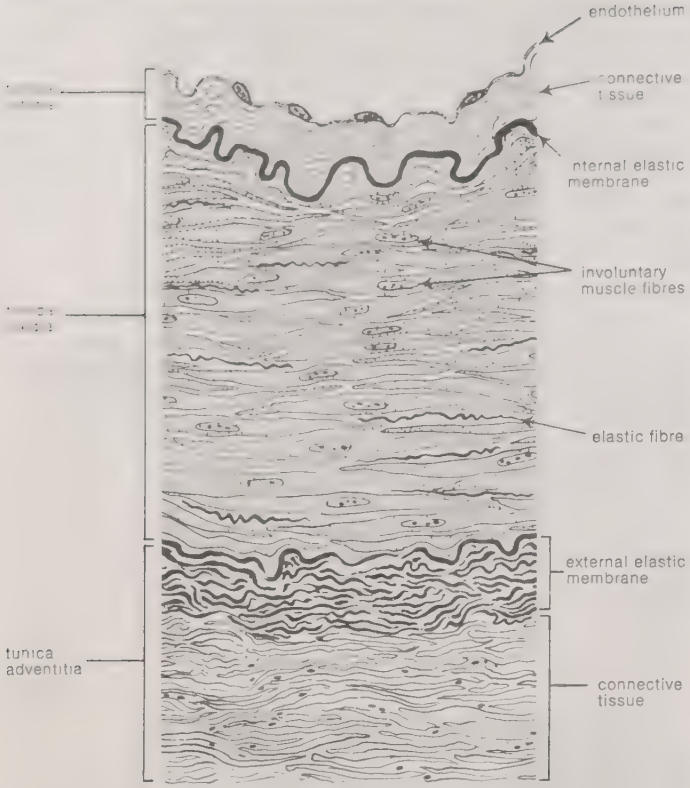

Figure 16: Transverse section of an artery.
From W. Bloom and D. Fawcett, *Textbook of Histology*, 9th ed., W.B. Saunders Company

size, they begin to exhibit the wall structure that is a characteristic of the arteries, though they are much thinner.

In veins, which function to conduct blood from the peripheral tissues to the heart, an endothelial lining is surrounded by the tunica media, which contains less muscle and elastic tissue than is found in the arterial wall. The outermost layer, tunica adventitia, is composed chiefly of connective tissue. Blood pressure in these vessels is extremely low as compared with that in the arterial system, and blood must exit at an even lower pressure. This creates a need for a special mechanism to keep blood moving on its return to the heart.

Venous valves

To achieve this, many veins possess a unique system of valves. These valves, formed by semilunar folds in the tunica intima, are present in pairs and serve to direct the flow of blood to the heart, particularly in an upward direction. As blood flows toward the heart, the flaps of the valves flatten against the wall of the vein; they then billow out to block the opening as the pressure of the blood and surrounding tissues fills the valve pocket. These valves are more abundant in the veins of the extremities than in any other parts of the body.

The veins are more distensible than arteries, and their walls are so constructed as to enable them to expand or contract. A major function of their contractility appears to be to decrease the capacity of the cardiovascular system by constriction of the peripheral vessels in response to the heart's inability to pump sufficient blood.

Veins tend to follow a course parallel to that of arteries but are present in greater number. Their channels are larger than those of arteries, and their walls are thinner. About 60 percent of the blood volume is in the systemic circulation, and 40 percent is normally present in the veins.

Pulmonary circulation

The pulmonary circuit consists of the right ventricle; the exiting pulmonary artery and its branches; the arterioles, capillaries, and venules of the lungs; and the pulmonary veins that empty into the left atrium.

The pulmonary trunk, the common stem of the pulmonary arteries, arises from the upper surface of the right ventricle and extends four to five centimetres beyond this origin before dividing into the right and left pulmonary arteries, which supply the lungs. The pulmonary valve, which has two leaflets, or cusps, guards the opening between the right ventricle and the pulmonary trunk. The trunk is relatively thin walled for an artery, having walls approximately twice the thickness of the vena cava and one-third that of the aorta. The right and left pulmonary arteries are short but possess a relatively large diameter. The walls are distensible; the vessels are able, therefore, to accommodate the stroke volume of the right ventricle, which is a necessary function equal to that of the left ventricle.

The pulmonary artery and its branches operate under high pressure in order to accommodate the great force of deoxygenated blood ejected from the right ventricle into the lungs. The pulmonary veins operate under lower pressure as they return oxygenated blood to the left atrium.

The pulmonary trunk passes diagonally upward to the left across the route of the aorta. Between the fifth and sixth thoracic vertebrae (at about the level of the bottom of the breastbone), the trunk divides into two branches—the right and left pulmonary arteries—which enter the lungs. After entering the lungs, the branches go through a process of subdivision, the final branches being capillaries. Capillaries surrounding the air sacs (alveoli) of the lungs pick up oxygen and release carbon dioxide. The capillaries carrying oxygenated blood join larger and larger vessels until they reach the pulmonary veins, which carry oxygenated blood from the lungs to the left atrium of the heart.

The arteries. *The aorta and its principal branches.* The aorta is the largest vessel in the systemic circuit, arising from the left ventricle. It is commonly said to have three regions: the ascending aorta, the arch of the aorta, and the descending aorta; the latter may be further subdivided into the thoracic and the abdominal aorta (Figure 17).

The three regions

Originating from the ascending portion of the aorta are the right and left coronary arteries, which supply the heart with oxygenated blood. Branching from the arch of the aorta are three large arteries named, in order of origin from the heart, the innominate, the left common carotid, and the left subclavian. These three branches supply the head, neck, and arms with oxygenated blood.

As the innominate (sometimes referred to as the brachiocephalic) artery travels upward toward the clavicle, or collarbone, it divides into the right common carotid and right subclavian arteries. The two common carotid arteries, one branching from the innominate and the other directly from the aorta, then extend in a parallel fashion on either side of the neck to the top of the thyroid cartilage (the principal cartilage in the voice box, or larynx), where they divide, each to become an internal and an external carotid artery. The external carotid arteries give off branches that supply much of the head and neck, while the internal carotids are responsible for supplying the forward portion of the brain, the eye and its appendages, and the forehead and nose.

The two vertebral arteries, one arising as a branch of the innominate and the other as a branch of the left subclavian artery, unite at the base of the brain to form the basilar artery, which in turn divides into the posterior cerebral arteries. The blood supply to the brain is derived mainly from vessels that may be considered as branches of the circle of Willis, which is made up of the two vertebral and the two internal carotid arteries and connecting arteries between them.

The arms are supplied by the subclavian artery on the left and by the continuation of the innominate on the right. At approximately the border of the first rib, both of these vessels become known as the axillary artery; this, in turn, becomes the brachial artery as it passes down the upper arm. At about the level of the elbow, the brachial artery divides into two terminal branches, the radial and ulnar arteries, the radial passing downward on the distal (thumb) side of the forearm, the ulnar on the medial side. Interconnections (anastomoses) between the two, with branches at the level of the palm, supply the hand and wrist.

Thoracic aorta

The thoracic (chest) portion of the descending aorta gives off branches that supply the viscera (visceral branches) and the walls surrounding the thoracic cavity (parietal branches). The visceral branches provide blood for the pericardium, lungs, bronchi, lymph nodes, and esophagus.

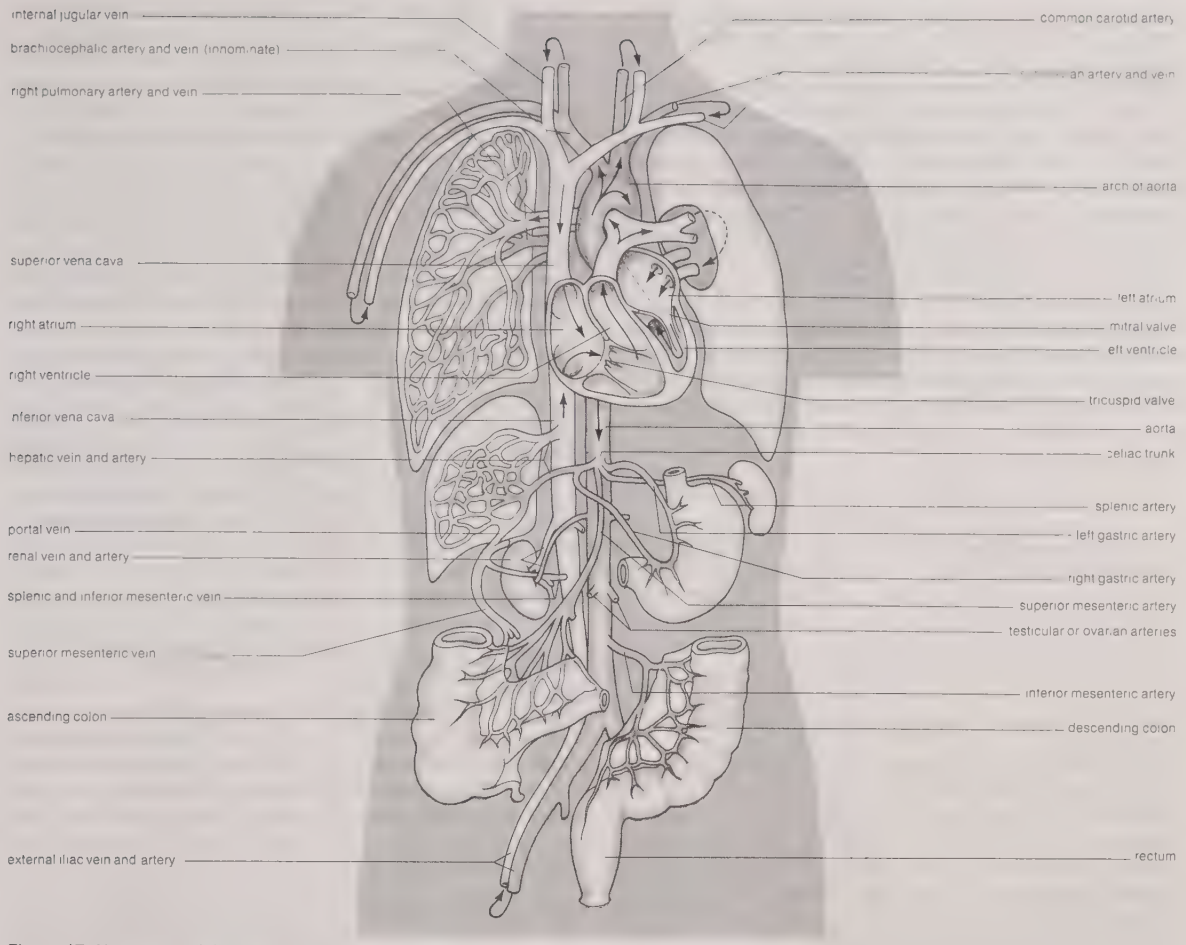

Figure 17: Human arterial supply and venous drainage of the organs.
From S. Jacob and C. Francone, *Structure and Function in Man* (1970); W.B. Saunders Co

The parietal vessels supply the intercostal muscles (the muscles between the ribs) and the muscles of the thoracic wall; they supply blood to the membrane covering the lungs and lining the thoracic cavity, the spinal cord, the vertebral column, and a portion of the diaphragm.

As the aorta descends through the diaphragm, it becomes known as the abdominal aorta and again gives off both visceral and parietal branches. Visceral vessels include the celiac, superior mesenteric, and inferior mesenteric, which are unpaired, and the renal and testicular or ovarian, which are paired. The celiac artery arises from the aorta a short distance below the diaphragm and almost immediately divides into the left gastric artery, serving part of the stomach and esophagus; the hepatic artery, which primarily serves the liver; and the splenic artery, which supplies the stomach, pancreas, and spleen.

The superior mesenteric artery arises from the abdominal aorta just below the celiac artery. Its branches supply the small intestine and part of the large intestine. Arising several centimetres above the termination of the aorta is the inferior mesenteric artery, which branches to supply the lower part of the colon. The renal arteries pass to the kidneys. The testicular or ovarian arteries supply the testes in the male and the ovaries in the female, respectively.

Parietal branches of the abdominal aorta include the inferior phrenic, serving the suprarenal (adrenal) glands, the lumbar, and the middle sacral arteries. The lumbar arteries are arranged in four pairs and supply the muscles of the abdominal wall, the skin, the lumbar vertebrae, the spinal cord, and the meninges (or spinal-cord coverings).

The abdominal aorta divides into two common iliac arteries, each of which descends laterally and gives rise to external and internal branches. The right and left external iliac arteries are direct continuations of the common iliacs and become known as the femoral arteries after passing through the inguinal region, giving off branches that supply structures of the abdomen and lower extremities.

At a point just above the knee, the femoral artery continues as the popliteal artery; from this arise the posterior and anterior tibial arteries. The posterior tibial artery is a direct continuation of the popliteal, passing down the lower leg to supply structures of the posterior portion of the leg and foot.

Arising from the posterior tibial artery a short distance below the knee is the peroneal artery; this gives off branches that nourish the lower leg muscles and the fibula (the smaller of the two bones in the lower leg) and terminates in the foot. The anterior tibial artery passes down the lower leg to the ankle, where it becomes the dorsalis pedis artery, which supplies the foot.

Pulse. An impulse can be felt over an artery that lies near the surface of the skin. The impulse results from alternate expansion and contraction of the arterial wall because of the beating of the heart. When the heart pushes blood into the aorta, the blood's impact on the elastic walls creates a pressure wave that continues along the arteries. This impact is the pulse. All arteries have a pulse, but it is most easily felt at points where the vessel approaches the surface of the body.

Discerning the pulse

The pulse is readily distinguished at the following locations: (1) at the point in the wrist where the radial artery approaches the surface; (2) at the side of the lower jaw where the external maxillary (facial) artery crosses it; (3) at the temple above and to the outer side of the eye, where the temporal artery is near the surface; (4) on the side of the neck, from the carotid artery; (5) on the inner side of the biceps, from the brachial artery; (6) in the groin, from the femoral artery; (7) behind the knee, from the popliteal artery; (8) on the upper side of the foot, from the dorsalis pedis artery.

The radial artery is most commonly used to check the pulse. Several fingers are placed on the artery close to the wrist joint. More than one fingertip is preferable because of the large, sensitive surface available to feel the pulse wave. While the pulse is being checked, certain data are recorded, including the number and regularity of beats per

minute, the force and strength of the beat, and the tension offered by the artery to the finger. Normally, the interval between beats is of equal length.

The veins. Venules collect blood from the capillaries and the blood channels known as sinusoids and unite to form progressively larger veins that terminate as the great veins, or venae cavae. In the extremities there are superficial and deep veins; the superficial lie just under the skin and drain the skin and superficial fasciae (sheets of fibrous tissue), while the deep veins accompany the principal arteries of the extremities and are similarly named. Interconnections between the superficial and the deep veins are frequent.

Venous blood enters the right atrium from three sources: the heart muscle by way of the coronary sinus; the upper body by way of the superior vena cava; and the lower body by way of the inferior vena cava (Figures 18 and 19).

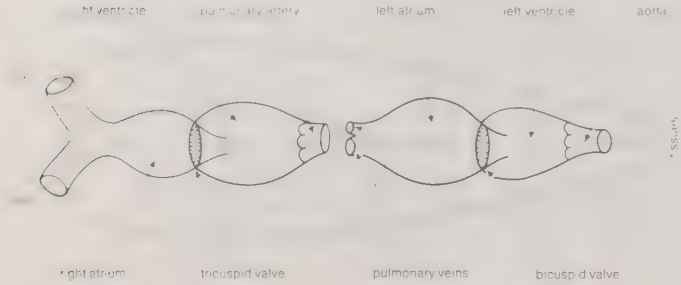

Figure 18: *Venous blood flow through the heart, lungs, and tissues of the body.*
Pulmonary circulation is indicated by solid arrows; systemic circulation by dashed arrows. SVC is superior vena cava; IVC is inferior vena cava.

Superior vena cava and its tributaries. Tributaries from the head and neck, the arms, and part of the chest unite to form the superior vena cava. Venous channels called venous sinuses lie between the two layers of the dura mater, the outer covering of the brain; they possess no valves. Venous drainage of the brain is effected by these sinuses and communicating vessels. The internal jugular vein is a continuation of this system downward through the neck; it receives blood from parts of the face, neck, and brain. At approximately the level of the collarbone, each unites with the subclavian vein of that side to form the innominate veins.

The external jugular vein is formed by the union of its tributaries near the angle of the lower jaw, or mandible. It drains some of the structures of the head and neck and pours its contents along with the subclavian into the innominate vein of the same side. All of the veins of the arm are tributaries of the subclavian vein of that side. They are found in both superficial and deep locations and possess valves. Most of the deep veins are arranged in pairs with cross connections between them.

Superficial and deep veins of the arm

Venous drainage of the hand is accomplished superficially by small anastomosing (interconnecting) veins that unite to form the cephalic vein, coursing up the radial (thumb) side of the forearm, and the basilic vein, running up the ulnar side of the forearm and receiving blood from the hand, forearm, and arm. The deep veins of the forearm include the radial veins, continuations of deep anastomosing veins of the hand and wrist, and the ulnar veins, both veins following the course of the associated artery. The radial and ulnar veins converge at the elbow to form the brachial vein; this, in turn, unites with the basilic vein at the level of the shoulder to produce the axillary vein. At the outer border of the first rib, the axillary vein becomes the subclavian vein, the terminal point of the venous system characteristic of the upper extremity.

The subclavian, external jugular, and internal jugular veins all converge to form the innominate vein. The right and left innominate veins terminate in the superior vena cava, which opens into the upper posterior portion of the right atrium.

In addition to the innominate veins, the superior vena cava receives blood from the azygous vein and small veins from the mediastinum (the region between the two lungs) and the pericardium. Most of the blood from the back and from the walls of the chest and abdomen drains into veins lying alongside the vertebral bodies (the weight-bearing portions of the vertebrae; Figure 19). These veins form what is termed the azygous system, which serves as a connecting link between the superior and inferior vena cava. The terminal veins of this system are the azygous, hemiazygous, and accessory hemiazygous veins. At the level of the diaphragm, the right ascending lumbar vein continues upward as the azygous vein, principal tributaries of which are the right intercostal veins, which drain the muscles of the intercostal spaces. It also receives tributaries from the esophagus, lymph nodes, pericardium, and right lung, and it enters into the superior vena cava at about the level of the fourth thoracic vertebra.

The left side of the azygous system varies greatly among individuals. Usually the hemiazygous vein arises just below the diaphragm as a continuation of the left ascending lumbar vein and terminates in the azygous vein. Tributaries of the hemiazygous drain the intercostal muscles, the esophagus, and a portion of the mediastinum. The accessory hemiazygous usually extends downward as a continuation of the vein of the fourth intercostal space, receiving tributaries from the left intercostal spaces and the left bronchus. It empties into the azygous vein slightly above the entrance of the hemiazygous.

Inferior vena cava and its tributaries. The inferior vena cava is a large, valveless, venous trunk that receives blood from the legs, the back, and the walls and contents of the abdomen and pelvis.

The foot is drained primarily by the dorsal venous arch, which crosses the top of the foot not far from the base of the toes. The arch is connected with veins that drain the sole. Superficially the lower leg is drained by the large and small saphenous veins, which are continuations of the dorsal venous arch. The small saphenous vein extends up the back of the lower leg to terminate usually in the popliteal vein. There is some interconnection with deep veins and with the great saphenous vein. The latter vein, the longest in the body, extends from the dorsal venous arch up the inside of the lower leg and thigh, receiving venous branches from the knee and thigh area and terminating in the femoral vein.

Superficial veins of the leg

Most blood from the lower extremity returns by way of

From S. Jacob and C. Francone, *Structure and Function in Man* (1970); W.B. Saunders Co.

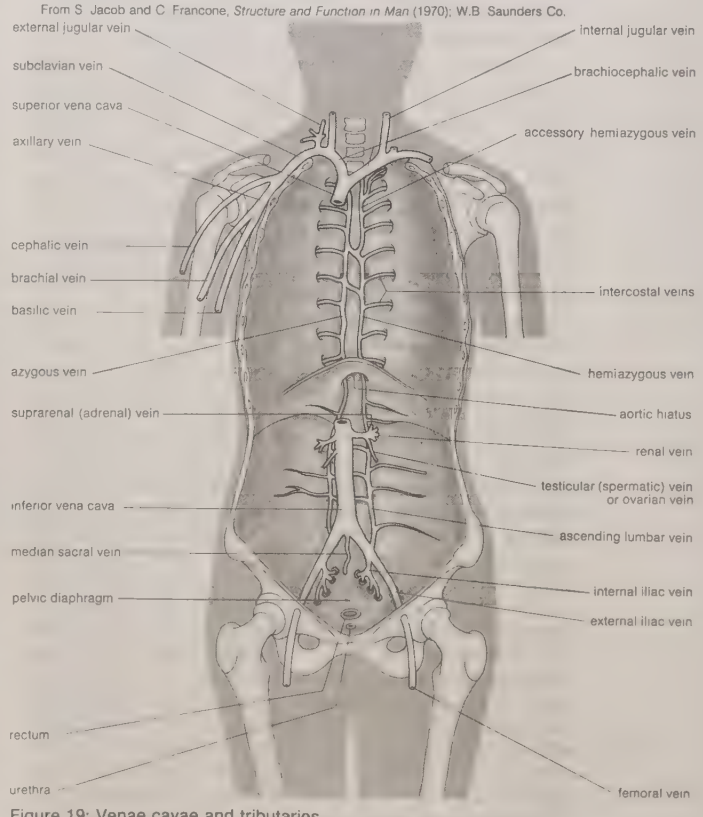

Figure 19: Venae cavae and tributaries.

the deep veins. These include the femoral and popliteal veins and the veins accompanying the anterior and posterior tibial and peroneal arteries. The anterior and posterior tibial veins originate in the foot and join at the level of the knee to form the popliteal vein; the latter becomes the femoral vein as it continues its extension through the thigh.

At the level of the inguinal ligament (which is at the anterior, diagonal border between the trunk and the thigh), the femoral vein becomes known as the external iliac vein; the latter unites with the internal iliac vein to form the common iliac vein. The internal iliac vein drains the pelvic walls, viscera, external genitalia, buttocks, and a portion of the thigh. Through the paired common iliac veins, the legs and most of the pelvis are drained. The two common iliacs then unite at a level above the coccyx (the lowest bone in the spine) to become the inferior vena cava. As it courses upward through the abdomen, the inferior vena cava receives blood from the common iliacs and from the lumbar, renal, suprarenal, and hepatic veins before emptying into the right atrium.

The pairs of lumbar veins (which drain blood from the loins and abdominal walls) are united on each side by a vertical connecting vein, the ascending lumbar vein; the right ascending lumbar vein continues as the azygous and the left as the hemiazygous. These veins usually enter separately into the inferior vena cava.

Renal veins lie in front of the corresponding renal artery; the right renal vein receives tributaries exclusively from the kidney, while the left receives blood from a number of other organs as well. The right suprarenal vein terminates directly in the inferior vena cava as does the right phrenic, above the gonadal vein. Two or three short hepatic trunks empty into the inferior vena cava as it passes through the diaphragm.

Portal system. The portal system may be described as a specialized portion of the systemic circulatory system. It is unique in that blood from the spleen, stomach, pancreas, and intestine first passes through the liver before it moves on to the heart. Blood flowing to the liver comes from the hepatic artery (20 percent) and the portal vein (80 percent); blood leaving the liver flows through the hepatic vein and then empties into the inferior vena cava. The hepatic arterial blood supplies oxygen requirements for the liver. Blood from the abdominal viscera, particularly the intestinal tract, passes into the portal vein and then into the liver. Substances in the portal blood are processed by the liver (see the article DIGESTION AND DIGESTIVE SYSTEMS).

Hepatic artery and portal vein

Venous pulmonary system. From the pulmonary capillaries, in which blood takes on oxygen and gives up carbon dioxide, the oxygenated blood in veins is collected first into venules and then into progressively larger veins; it finally flows through four pulmonary veins, two from the hilum of each lung. (The hilum is the point of entry on each lung for the bronchus, blood vessels, and nerves.) These veins then pass to the left atrium, where their contents are poured into the heart.

The capillaries. The vast network of some 10,000,000,000 microscopic capillaries functions to provide a method whereby fluids, nutrients, and wastes are exchanged between the blood and the tissues. Even though microscopic in size, the largest capillary being approximately 0.2 millimetre in diameter (about the width of the tip of a pin), the great network of capillaries serves as a reservoir normally containing about one-sixth of the total circulating blood volume. The number of capillaries in active tissue, such as muscle, liver, kidney, and lungs, is greater than the number in tendon or ligament, for example; the cornea of the eye, epidermis, and hyaline cartilage (semitransparent cartilage such as is found in joints) are devoid of capillaries.

The interconnecting network of capillaries into which the arterioles empty is characterized not only by microscopic size but also by extremely thin walls only one cell thick. The vessels are simply tubular continuations of the inner lining cells of the larger vessels, normally uniform in size, usually three to four endothelial cells in circumference, except toward the venous terminations, where they become slightly wider, four to six cells in circumference. A thin membrane, called a basement membrane, surrounds these cells and serves to maintain the integrity of the vessel.

A single capillary unit consists of a branching and interconnecting (anastomosing) network of vessels, each averaging 0.5 to 1 millimetre in length. The wall of the capillary is extremely thin and acts as a semipermeable membrane that allows substances containing small molecules, such as oxygen, carbon dioxide, water, fatty acids, glucose, and ketones, to pass through the membrane. Oxygen and nutritive material pass into the tissues through the wall at the arteriolar end of the capillary unit; carbon dioxide and waste products move through the membrane into the vessel at the venous end of the capillary bed. Constriction and dilation of the arterioles is primarily responsible for regulating the flow of blood into the capillaries. Muscular gatekeepers, or sphincters, in the capillary unit itself, however, serve to direct the flow to those areas in greatest need.

There are three modes of transport across the cellular membrane of the capillary wall. Substances soluble in the lipid (fatty) membrane of the capillary cells can pass directly through these membranes by a process of diffusion. Some substances needed by the tissues and soluble in water but completely insoluble in the lipid membrane pass through minute water-filled passageways, or pores, in the membranes by a process called ultrafiltration. Only $^{1}/_{1,000}$ of the surface area of capillaries is represented by these pores. Other substances, such as cholesterol, are transported by specific receptors in the endothelium.

In the fetus, oxygenated blood is carried from the placenta to the fetus by the umbilical vein. It then passes to the inferior vena cava of the fetus by way of a vessel called the ductus venosus. From the inferior vena cava, the blood enters the right atrium, then passes through the foramen ovale into the left atrium; from there it moves into the left ventricle and out the aorta, which pumps the oxygenated blood to the head and upper extremities. Blood from the upper extremities returns via the superior vena cava into the right atrium, where it is largely deflected into the right ventricle.

Fetal circulation

From the right ventricle, a portion of the blood flows into the pulmonary artery to the lungs. The largest fraction flows through an opening, the ductus arteriosus, into the aorta. It enters the aorta beyond the point at which the blood of the head leaves. Some of the blood supplies the lower portion of the body. The remainder returns to the placenta via the umbilical arteries, which branch off from the internal iliac arteries.

The changes that take place at birth and that permit routing of the blood through the pulmonary system instead of the umbilical vessels have been described above in the section on the origin and development of the heart.

EVALUATING THE CARDIOVASCULAR SYSTEM

Certain diagnostic techniques with respect to the heart and blood vessels are important factors in determining the degree of disease and their appropriate medical and surgical treatment.

Invasive techniques. *Right-heart catheterization.* Right-heart catheterization is performed by insertion of a catheter (a long tube) into the cubital vein (at the bend of the elbow), the saphenous vein (in the inner thigh), or the femoral vein (at the groin). The catheter, which is opaque to X ray, is advanced into the right atrium, right ventricle, and pulmonary artery under fluoroscopy. This procedure makes it possible to measure pressure and oxygen saturation in the right heart chamber itself and thus to diagnose abnormalities in the valves.

Left-heart catheterization. Left-heart catheterization is accomplished by introducing a catheter into the brachial or femoral artery (in the upper arm and thigh, respectively) and advancing it through the aorta across the aortic valve and into the left ventricle. Mitral and aortic valvular defects and myocardial disease can be evaluated by this technique.

Angiocardiography and arteriography. Angiocardiography permits direct visualization of the chambers and great vessels of the heart from injections of dyes that are opaque to X rays. Anatomic defects, such as congenital and

acquired lesions, can be detected readily. Left ventriculography (X-ray pictures of the left ventricle) provides information about the synchrony and adequacy of the forces of contraction in areas of the left ventricle. Arteriography (X-ray pictures of an artery after the injection of dyes that are opaque to X rays) of the coronary arteries permits identification, localization, and assessment of the extent of obstructive lesions within these arteries. It is the most important means of defining the presence and severity of coronary atherosclerosis and, in conjunction with left ventriculography, the related state of myocardial function. Although invasive techniques involving left ventricular catheterization and radio contrast angiocardiography and arteriography provide reliable measurements of ejection fraction and regional formation, they have limited applications.

Echocardiography

Noninvasive techniques. The term echocardiography refers to a group of tests that use ultrasound (sound waves above frequencies audible to humans) to examine the heart and record information in the form of echoes, or reflected sonic waves. M-mode echocardiography records the amplitude and the rate of motion of moving objects, such as valves, along a single line with great accuracy. M-mode echocardiography, however, does not permit effective evaluation of the shape of cardiac structures. nor does it depict lateral motion (*i.e.,* motion perpendicular to the ultrasonic beam). Real-time (cross-sectional or two-dimensional) echocardiography depicts cardiac shape and lateral movement not available in M-mode echocardiography by moving the ultrasonic beam very rapidly, and such recording may be displayed on film or videotape. New techniques allow measurement by ultrasonography of rates of flow and pressures, for example, across heart valves.

Radionuclide imaging (radioactive nuclides) provides a safe, quantitative evaluation of cardiac function and a direct measurement of myocardial blood flow and myocardial metabolism. Radionuclide imaging is used to evaluate the temporal progress of cardiac disease, hemodynamics, and the extent of myocardial damage during and after infarction and to detect pulmonary infarction following emboli. The primary requirement of radionuclide imaging is that the bolus of radionuclide should remain within the blood vessels during its first passage through the right and left sides of the heart. The second requirement is that the physical properties of the radionuclide be satisfactory with respect to the instrumentation being used.

The radionuclide used in virtually all phases of radionuclide imaging is technetium-99. It has the disadvantage of a long half-life (six hours), however, and other radionuclides with shorter half-lives are also used. These radionuclides all emit gamma rays, and a scintillation camera is used to detect gamma-ray emission. The data are assessed with the R wave of the electrocardiogram as a time marker for the cardiac cycle. Radionuclide cineangiography is a further development of radionuclide imaging. These techniques are used to assess myocardial damage, left ventricular function, valve regurgitation, and, with the use of radionuclide potassium analogues, myocardial perfusion.

Measures of heart metabolism

There are techniques that measure metabolism in the myocardium using the radiotracer method (*i.e.,* a radioactive isotope replaces a stable element in a compound, which is then followed as it is distributed through the body). Positron emission tomography uses positron radionuclides that can be incorporated into true metabolic substrates and consequently can be used to chart the course of selected metabolic pathways, such as myocardial glucose uptake and fatty-acid metabolism. Magnetic resonance imaging (MRI; also called nuclear magnetic resonance [NMR]), also allows high resolution tomographic (one-plane) and three-dimensional imaging of tissues. Magnetic resonance imaging uses magnetic fields and radio frequencies to penetrate bone and obtain clear images of the underlying tissues. (M.F.O./S.W.J.)

Cardiovascular system diseases and disorders

Diseases of the heart and blood vessels constitute one of the major human health problems of modern times. Life depends on the functioning of the heart; thus, the heart is involved in all death, but this does not account for its prominence in causing death. To some degree, as medical science advances, more people are saved from other illnesses, only to die from one of the unsolved and uncontrolled disorders of the cardiovascular system. Some forms of cardiovascular diseases are becoming less frequent causes of death, and continued research and preventive measures may provide even greater benefits.

Heart disease as such was not recognized in nontechnological cultures, but the beating heart and its relationship to death have always been appreciated. Sudden death, now usually attributed to heart disease, was recognized as early as the 5th century BC by the Greek physician Hippocrates and was noted to be more common in the obese. The role of disease in affecting the heart itself did not become apparent until the 17th century, when examination of the body after death became acceptable.

Gradually, the involvement of the heart valves, the blood vessels, and the heart muscle was observed and categorized in an orderly fashion. The circulation of the blood through the heart was described in 1628 by the British physician William Harvey. The recognition of the manifestations of heart failure came later, as did the ability to diagnose heart ailments by physical examination through the techniques of percussion (thumping), auscultation (listening) with the stethoscope, and other means. It was not until early in the 20th century that the determination of arterial blood pressure and the use of X rays for diagnosis became widespread.

In 1912 James Bryan Herrick, a Chicago physician, first described what he called coronary thrombosis (he was describing symptoms actually caused by myocardial infarction; see below). Angina pectoris (described and discussed in a later section) had been recorded centuries earlier. Cardiovascular surgery in the modern sense began in the 1930s, and open-heart surgery in the 1950s.

Incidence of heart disease

The exact incidence of heart disease in the world population is difficult to ascertain because complete and adequate public health figures for either prevalence or deaths are not available. In the more technologically developed countries of the world, such as the United States, the United Kingdom, and most other European countries, arteriosclerotic heart disease (heart disease resulting from thickening and hardening of the artery walls; see below) constitutes by far the most predominant form. In other areas, such as the countries of Central Africa, other forms of heart disease, often nutritional in nature, are a common cause of death. In Asia and the islands of the Pacific, hypertensive cardiovascular disease, disease involving high blood pressure, constitutes a major health hazard. (J.V.W./Ed.)

CONGENITAL HEART DISEASE

The heart's complicated evolution during embryological development presents the opportunity for many different types of congenital defects to occur. Congenital heart disease is one of the important types of diseases affecting the cardiovascular system, with an incidence of about eight per 1,000 live births. In most patients the causes appear to fit in the middle of a continuum from primarily genetic to primarily environmental.

Of the few cases that have a genetic nature, the defect may be the result of a single mutant gene, while in others it may be associated with a chromosomal abnormality, the most common of which is Down's syndrome, in which about 50 percent of afflicted children have a congenital cardiac abnormality. In the even smaller number of cases of an obvious environmental cause, a variety of specific factors are evident. The occurrence of rubella (German measles) in a woman during the first three months of pregnancy is caused by a virus and is associated in the child with patent ductus arteriosus (nonclosure of the opening between the aorta and pulmonary artery). Other viruses may be responsible for specific heart lesions, and a number of drugs, including antiepileptic agents, are associated with an increased incidence in congenital heart disease.

In most cases, congenital heart disease is probably caused by a variety of factors, and any genetic factor is usually unmasked only if it occurs together with the appropriate environmental hazard. The risk of a sibling of a child

with congenital heart disease being similarly affected is between 2 and 4 percent. The precise recurrence can vary for individual congenital cardiovascular lesions.

Prenatal diagnosis

Prenatal diagnosis of congenital cardiovascular abnormalities is still at an early stage. The most promising technique is ultrasonography, used for many years to examine the fetus in utero. The increasing sophistication of equipment has made it possible to examine the heart and the great vessels from 16 to 18 weeks of gestation onward and to determine whether defects are present. Amniocentesis (removal and examination of a small quantity of fluid from around the developing fetus) provides a method by which the fetal chromosomes can be examined for chromosomal abnormalities associated with congenital heart disease. In many children and adults the presence of congenital heart disease is detected for the first time when a cardiac murmur is heard. A congenital cardiovascular lesion is rarely signaled by a disturbance of the heart rate or the heart rhythm.

Congenital cardiac disturbances are varied and may involve almost all components of the heart and great arteries. Some may cause death at the time of birth, others may not have an effect until early adulthood, and some may be associated with an essentially normal life span. Nonetheless, about 40 percent of all untreated infants born with congenital heart disease die before the end of their first year.

Congenital heart defects can be classified into cyanotic and noncyanotic varieties. In the cyanotic varieties, a shunt bypasses the lungs and delivers venous (deoxygenated) blood from the right side of the heart into the arterial circulation. The infant's nail beds and lips have a blue colour due to the excess deoxygenated blood in their systems. Some infants with severe noncyanotic varieties of congenital heart disease may fail to thrive and may have breathing difficulties.

Abnormalities of individual heart chambers. Abnormalities of the heart chambers may be serious and even life threatening. In hypoplastic left heart syndrome, the left-sided heart chambers, including the aorta, are underdeveloped. Infants born with this condition rarely survive more than two or three days. In other cases, only one chamber develops adequately. Survival often depends on the presence of associated compensatory abnormalities such as continued patency of the ductus arteriosus or the presence of a septal defect, which may allow either decompression of a chamber under elevated pressure or beneficial compensatory intracardiac shunting either from right to left or from left to right.

Abnormalities of the atrial septum. The presence of a septal defect allows blood to be shunted from the left side of the heart to the right, with an increase in blood flow and volume within the pulmonary circulation. Over many years the added burden on the right side of the heart and the elevation of the blood pressure in the lungs may cause the right side of the heart to fail.

Locations of defects

Defects in the atrial septum may be small or large and occur most commonly in the midportion in the area prenatally occupied by the aperture called the foramen ovale. Defects lower on the atrial septum may involve the atrioventricular valves and may be associated with incompetence of these valves. In its most extreme form, there may be virtually no septum between the two atrial chambers. Atrial septal defect is a noncyanotic type of congenital heart disease and usually is not associated with serious disability during childhood. A small defect may be associated with problems in young adults, although deterioration can occur in later life. Atrial septal defects, unless small, must usually be closed in childhood.

Abnormalities of the ventricular septum. Defects in the interventricular septum, the partition that separates the lower chambers of the heart, may be small or large, single or multiple, and may exist within any part of the ventricular septum. Small defects are among the most common congenital cardiovascular abnormalities and may be less life threatening, since many such defects close spontaneously. Small defects often create loud murmurs but, because they restrict the flow of blood from left to right, no significant change in the circulation occurs. On the other hand, when a defect is large a significant amount of blood is shunted from the left ventricle to the right, with a high flow and volume of blood into the pulmonary circulation.

The pulmonary circulation may be damaged by the stresses imposed by a high blood flow over a long period of time. If unchecked, this damage can become irreversible. A further hazard in both small and large ventricular septal defects is the increased risk of bacterial endocarditis (inflammation of the heart lining as a result of bacterial infection). This risk is likely to be high during procedures such as dental extractions, when infection may enter the bloodstream.

Ventricular septal defects are often combined with other congenital cardiac defects. The best known of these is tetralogy of Fallot, named for the French physician Étienne-Louis-Arthur Fallot, who first described it. In this condition there is a ventricular septal defect, pulmonary stenosis (narrowing of the opening to the pulmonary artery), deviation of the aorta to override the ventricular septum above the ventricular septal defect, and right ventricular hypertrophy (thickening of the muscle of the right ventricle). As a result of the obstruction imposed by the pulmonary stenosis, deoxygenated venous blood is shunted from the right to the left side of the heart into the arterial circulation. A child with this cyanotic form of congenital heart disease can survive beyond infancy, but few survive to adulthood without surgery.

Tetralogy of Fallot

Abnormal origins of the great arteries. In many complex forms of congenital heart disease, the aorta and pulmonary artery do not originate from their normal areas of the ventricles. In one of the most common of such cases—transposition of the great arteries—the aorta originates from the right ventricle and receives deoxygenated blood from the superior and inferior venae cavae, and the pulmonary artery arises from the left ventricle and receives fully oxygenated pulmonary venous blood. Survival in such cases depends on a naturally occurring communication between the two sides of the heart that allows oxygenated blood to enter the aorta; if such a communication is not present naturally, it may be created medically or surgically. Both the aorta and the pulmonary artery may originate from the right ventricle; this form of abnormal origin of the arteries usually is associated with a ventricular septal defect and, on occasion, pulmonary stenosis. This combination of defects is a severe form of cyanotic heart disease.

Abnormalities of the valves. The most common congenital abnormality of the cardiac valves affects the aortic valve. The normal aortic valve usually has three cusps, or leaflets, but the valve is bicuspid in 1 to 2 percent of the population. A bicuspid aortic valve is not necessarily life threatening, but in some persons it becomes thickened and obstructed (stenotic). With age the valve may also become incompetent or act as a nidus (focus of infection) for bacterial endocarditis. Congenital aortic valve stenosis, if severe, results in hypertrophy of the left ventricular myocardium and may rarely be responsible in asymptomatic individuals for sudden death. Even minor forms of aortic valve stenosis may grow progressively severe, and are likely, with the passage of time, to require surgical treatment.

In contrast to aortic valve stenosis, pulmonary valve stenosis, if mild, is usually well tolerated and does not require surgical treatment. More severe forms of the disease may require surgery or balloon dilation (see below *Surgical treatment of the heart*).

Abnormalities of the myocardium and endocardium. Congenital abnormalities in the myocardium, for example, tumours, may be present at birth, but they are rare. Abnormalities of the endocardium may be present at birth, but they are also rare. They include fibroelastosis, a disease in which the endocardium develops a thick fibrous coat that interferes with the normal contraction and relaxation of the heart. This condition cannot be treated surgically and is usually life threatening.

Abnormalities of the coronary arteries. The coronary arteries may arise abnormally from a pulmonary artery rather than from the aorta, with the result that deoxygenated blood instead of oxygenated blood flows through

the heart muscle. Abnormal openings, called coronary arterial venous fistulas, may be present between the coronary arteries and chambers of the heart. One or more of the three main coronary arteries may be absent. If necessary, most coronary arterial abnormalities can be corrected surgically.

Abnormalities of the aorta. One of the most common congenital cardiovascular abnormalities involves the aorta. In coarctation of the aorta there is a narrowing of the aortic wall usually at that portion of the aorta just beyond the site at which the main blood vessel to the left arm (the subclavian artery) originates. As a result of the narrowing or obstruction at this point, blood flow to the lower half of the body is diminished and hypertension develops in the upper half of the body. This defect may give rise to heart failure in early infancy or complications in later childhood and adulthood.

Patent ductus arteriosus

During fetal life and immediately after birth, the ductus arteriosus is a channel that connects the pulmonary artery and the first segment of the descending thoracic aorta. The function of this duct in utero is to shunt blood away from the lungs. If the ductus remains open after birth, excessive blood may flow into the lungs, resulting in pulmonary congestion and heart failure. Spontaneous closure of the ductus arteriosus may be delayed in premature newborn infants, exacerbating the respiratory problems common to them. If necessary, the ductus arteriosus can be induced to close with drugs in premature infants or surgically closed in older infants and children. Finally, there may be direct communication between the aorta and pulmonary arteries because the truncus arteriosus has either partially or completely failed to partition.

Anomalous pulmonary venous return. The pulmonary veins from the right and left lungs may connect either directly or indirectly to the right, instead of the left, atrium. In this condition the abnormal venous channel draining to the right side of the heart may become obstructed. Infants born with total anomalous (abnormal) pulmonary venous drainage usually develop problems within the first few weeks or months and thus require cardiac surgery. Partial forms of anomalous pulmonary venous return, in which only one or two pulmonary veins are connected abnormally, may have few symptoms, although surgical correction may be done if required.

Anomalies of the vena cava. The most common abnormalities of the venae cavae, the major veins returning venous blood to the right side of the heart, are a persistent left superior vena cava (normally there is only one superior vena cava opening to the right side of the heart) and an abnormal connection of the inferior vena cava to the heart. These abnormalities are frequently associated with intracardiac structural faults. (M.F.O./M.J.G.)

ACQUIRED HEART DISEASE

Atherosclerosis. Atherosclerosis is a type of thickening and hardening of the medium- and large-sized arteries. When affecting the coronary arteries, it accounts for a large proportion of heart attacks and cases of ischemic (inadequate blood supply to a region due to a constriction or obstruction of a blood vessel) heart disease. Atherosclerosis also accounts for many strokes (those due to cerebral ischemia and infarction), numerous instances of peripheral vascular disease, and most aneurysms (a dilation in the wall of a blood vessel to form a blood-filled sac) of the aorta, which can rupture and cause fatal hemorrhage.

Coronary atherosclerosis

The basis of coronary artery disease is the slow development of areas of thickening in the coronary arteries. These thickenings are called atherosclerotic plaques or atheromatous lesions and they develop early in life, progressing over a period of many years with phases of quiescence or even regression interspersed with periods of progression. Such coronary atheromatous lesions are found in virtually all adults in the industrialized world although most persons never have signs or symptoms of heart disease. In others, however, atheromatous lesions intrude into the lumen of the coronary arteries and progressively impede blood flow to the myocardium, leading to the clinical syndromes of coronary heart disease (Figure 20).

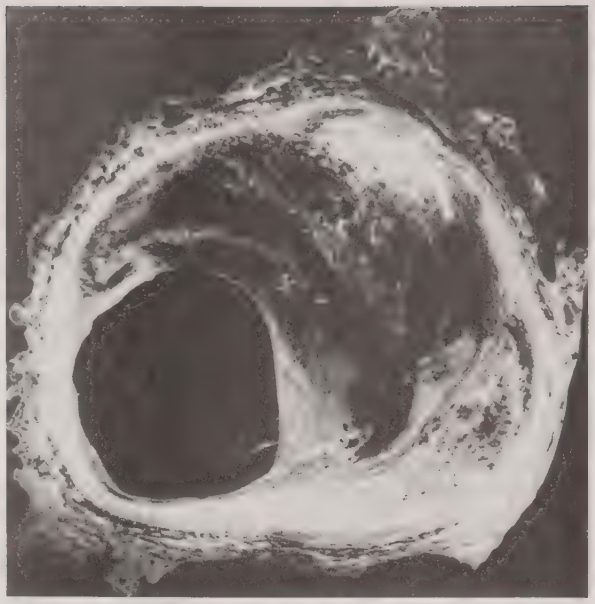

Figure 20: *A typical atheromatous plaque in a coronary artery.* The plaque has reduced the lumen (large dark circle at bottom left) to 30 percent of its normal size. The white areas are lipid and cholesterol deposits. The darker layers represent fibrous areas, probably resulting from earlier incorporation of thrombi from the lumen.

Two major elements of the atheromatous lesion determine its progress. One is the accumulation of cholesterol at the points of thickening and the other is the incorporation of minute clots, or thrombi, into the endothelial (inner) surface of the artery. Accumulation of cholesterol in atherosclerotic lesions is related to the concentration of cholesterol-carrying lipoproteins in the blood that flows through the coronary arteries. Elevation of the concentration of these lipoproteins is primarily determined by genetic factors but is also influenced by environmental factors, such as a high-fat diet. Environmental and genetic factors may interact adversely. The inverse of this relationship is also true; human beings with low levels of cholesterol, as well as many species of mammals that do not have an excess of cholesterol-carrying lipoproteins, rarely develop atherosclerosis.

There are alternative views on what actually causes the irreversible accumulation of cholesterol-carrying lipoproteins to form atheromatous lesions. One theory is that the degree of elevation of plasma cholesterol, in association with defective receptors on the lining of the arteries and arterioles, determines whether cholesterol accumulates. The second is that there is a low-grade inflammatory process in this lining (the endothelium) that leads to the formation of microthrombi on the surface and the trapping of cholesterol-carrying lipoproteins on the arterial wall.

It is probable that these two previously divergent theories of the development of atherosclerosis—the accumulation of cholesterol-carrying lipoproteins and endothelial thrombosis (formation of a clot of blood products)—may be combined by accepting that both occur. Under most conditions incorporation of cholesterol-rich lipoproteins is the predominant factor in determining whether or not plaques progressively develop. The endothelial injury that results or may occur independently leads to involvement of two cell types circulating in the blood—platelets and monocytes. Platelets adhere to areas of endothelial injury and to themselves. They trap fibrinogen, a plasma protein, leading to the development of platelet-fibrinogen thrombi. Platelets, monocytes, and other elements of the blood release hormones, called growth factors, that stimulate proliferation of muscle cells in arteries.

Distribution of lesions

Atherosclerotic lesions are focal in nature, and their distribution is determined by the interrelation of hemodynamic physical forces such as blood pressure, blood flow, and turbulence within the lumen. These lead to physical forces of parallel strain, or shear, on the endothelial lining, giving rise to areas of relatively positive and

negative pressure. These hemodynamic forces are particularly important in the system of coronary arteries, where there are unique pressure relationships. The flow of blood through the coronary system into the myocardium takes place during the phase of ventricular relaxation (diastole) and virtually not at all during the phase of ventricular contraction (systole). During systole, the external pressure on coronary arterioles is such that blood cannot flow forward, and the system of coronary arteries is the most extreme example of phasic blood flow in the body. The external pressure exerted by the contracting myocardium on coronary arteries also influences the distribution of atheromatous obstructive lesions.

Arterial atheromatous lesions may undergo reversal, although much of the evidence comes from changes that have been observed in artificial experimental circumstances in primates and early lesions in human femoral arteries. The extent to which it is possible to induce regression of advanced obstructive lesions in human coronary arteries depends upon a better knowledge of the spontaneous changes that occur in these lesions and upon improvements in the methods of their measurement during life.

Coronary artery disease. Coronary artery disease is a term describing those diseases, which also occur in other arteries, that lead to obstruction of the flow of blood in the vessel. It is commonly used synonymously with the specific entity of atheromatous intrusion into the artery lumen. Coronary heart disease is a term used to describe the symptoms and features that can result from advanced coronary artery disease. The same symptoms are also called ischemic heart disease because the symptoms result from the development of myocardial ischemia. There is no one-to-one relationship between coronary atherosclerosis and the clinical symptoms of the disease or between coronary artery disease and coronary heart disease.

Coronary artery disease due to atherosclerosis is present to varying degrees in all adults in industrialized communities. Symptoms of disease, however, will occur only when the extent of the lesions or the speed of their development (acute thrombosis) reduces the flow of blood to the myocardium below a critical level. One or more major coronary arteries may progressively narrow without leading to any symptoms of coronary heart disease, provided the area of the heart muscle supplied by that artery is adequately perfused with blood from another coronary artery circuit. The small coronary arteries anastamose (interconnect) and are not, as previously thought, end arteries. Thus, they can open up and provide a collateral, or supportive, circulation that protects against progressive occlusion (obstruction). Exercise improves coronary collateral flow and for this reason may protect against coronary heart disease.

Although coronary artery disease is most frequently caused by atherosclerosis, inflammation of the blood vessels may, in rare cases, cause obstructive lesions of the coronary vessels. In persons with familial hypercholesterolemia, the disease process may involve the mouth of the coronary vessels as they leave the aorta and cause obstruction to blood flow. On rare occasions, clots arising from the left atrium or left ventricle may enter the coronary vessels and cause acute obstruction and symptoms of disease.

Triggers of coronary heart disease

There are influences, or "triggers," that convert coronary artery disease into coronary heart disease; these include coronary thrombosis, vasomotor influences such as coronary spasm, and the hemodynamic needs of the myocardium. Influences within the myocardium itself also may increase the demand for blood flow above the level available, making the myocardium vulnerable to alterations in function, contractility, and the maintenance of normal rhythm. These interrelationships are indicated in Figure 21.

Coronary heart disease. Coronary heart disease is a general term for a number of syndromes. Ischemic heart disease, an alternative term, is actually more correct because the syndromes described are all to some degree manifestations of myocardial ischemia (a lack of blood supply to the myocardium).

Coronary heart disease includes a number of interdependent syndromes: angina pectoris, acute myocardial infarction, and sudden cardiac death (due to lethal arrhythmias). There are also features of coronary occlusion (blockage of a coronary artery), including phasic abnormalities during rest and exercise electrocardiograms that indicate the presence of myocardial ischemia. Knowledge of the mechanisms that lead to a particular syndrome is inexact. Thus, a coronary thrombosis may lead to myocardial infarction in one person, sudden death in another, a minor episode of angina in a third, or no symptoms at all in a fourth. There is, however, no alternative to using the orthodox syndromes as the means of recognizing and recording the incidence of coronary heart disease.

From M.F. Oliver, "Prevention of Coronary Heart Disease—Propaganda, Promises, Problems and Prospects," *Circulation* (January 1986)

Epidemiology. There is an uneven geographic distribution of coronary heart disease. It is responsible for one-third to one-half of the deaths in most industrialized countries and is the most common single cause of death in North America and Europe. The disease is relatively uncommon, however, in Asia (including China, Japan, India, and the Middle East), Central Africa, and Central and South America. Many studies have linked the geographic differences in coronary heart disease with various aspects of life-style, such as cigarette smoking, diet, physical inactivity, and obesity.

Risk factors. Three main risk factors have been identified: cigarette smoking, a high level of cholesterol in the blood (hypercholesterolemia), and high blood pressure (hypertension). Important as these risk factors are, they are found only in about one-half of those who experience heart attacks. The proportion of persons with any or all of these three risk factors is greater in young and middle-aged adults than in older adults. It is impossible to incriminate any one of these risk factors over another, since the manifestations of coronary heart disease are undoubtedly due to many independent and interdependent influences, but the coexistence of the three greatly increases the risk of developing coronary heart disease.

The familial predisposition to the disease is not well understood, although it is stronger in families with hypercholesterolemia and hypertension. It is most likely to develop prematurely in the presence of polygenic forms, or the rare monogenic form, of familial hypercholesterolemia. There is a progressive relationship between serum cholesterol concentrations and the incidence of coronary heart disease. This is also true for hypertension. Of the three major risk factors, however, excessive cigarette smoking is probably the most important. Other influences—such as a predisposition to develop thrombosis, diabetes mellitus, physical inactivity, obesity, and, rarely, oral contraceptives—may induce premature coronary heart disease in susceptible persons.

Cigarette smoking and heart disease

Angina pectoris. The term angina pectoris was first used in 1772 by the British physician William Heberden when he wrote:

> There is a disorder of the breast. . . . The seat of it, and sense of strangling and anxiety, with which it is attended, may make it not improperly be called angina pectoris. Those, who are afflicted with it, are ceased [*sic*] while they are walking and most particularly when they walk soon after eating, with a painful and most disagreeable sensation in the breast, which seems as it would take their breath away, if it were to increase

or to continue; the moment they stand still, all this uneasiness vanishes.

Heberden's initial description is still accurate; however, there are no truly characteristic symptoms of angina pectoris. While the chest discomfort may be variously described as "constricting," "suffocating," "crushing," "heavy," or "squeezing," there are many patients in whom the quality of the sensation is imprecise. The discomfort is usually, but not always, behind the breastbone, but pain radiating to the throat or jaw or down the inner sides of either arm is common. There may be no physical abnormalities, and an electrocardiogram may be normal or show only transient changes with exercise.

Coronary arteriography assesses the extent of coronary artery occlusion, which may vary from a small increase in coronary artery muscle tone at a partly occluded site in a branch of one of the three main coronary arteries, to a 90 percent or greater occlusion of the left main coronary artery with involvement of other major coronary arteries. But the extent of coronary artery disease revealed by coronary arteriography does not predicate action or treatment.

The myocardial ischemia that causes angina is due to a disturbance of the balance between myocardial demands and supply. If demands are reduced sufficiently, the temporarily endangered supply may be adequate. The disturbance of the equilibrium may be short-lived and may correct itself. Unstable angina has an appreciably worse prognosis than stable angina because of a higher risk of myocardial infarction and sudden cardiac death, and it requires daily observation and active intervention.

When coronary arteriography reveals relatively isolated, incompletely obstructive lesions, there are two alternative treatments—medication or coronary angioplasty (balloon dilation of the localized obstruction by a special catheter; see Figure 22). When coronary arteriography reveals a severe occlusion of the left main coronary artery or proximally in one or more of the major arteries, coronary artery bypass graft surgery may be necessary.

In unstable angina pectoris, coronary arteriography may help determine whether coronary angioplasty or coronary artery bypass surgery is needed. Drugs that cause coronary dilation and peripheral arterial vasodilation, and that reduce the load on the heart, are usually necessary. Drugs that reduce the work of the heart by blocking adrenoreceptors (receptors in the heart that respond to epinephrine) and drugs that reduce a thrombogenic tendency are given at this stage. For patients with stable angina, drugs that reduce the heart's work are administered.

Myocardial infarction. A syndrome of prolonged, severe chest pain was first described in the medical literature in 1912 by James Brian Herrick, who attributed the syndrome to coronary thrombosis, the development of a clot in a major blood vessel serving the heart. As a result, the disorder was termed coronary thrombosis, or coronary occlusion (blockage of a coronary artery). Later evidence indicated, however, that, though thrombotic occlusion of an atheromatous lesion in a coronary artery is the most common cause of the disorder, the manifestations are the result of the death of an area of heart muscle (infarction). The term myocardial infarction, therefore, is more appropriate. The more general and less specific term heart attack may be more desirable because of these difficulties in describing the causation of the disease entity.

Characteristics of myocardial infarction

Myocardial infarction is characterized by cellular death (necrosis) of a segment of the heart muscle. Generally, it involves an area in the forward wall of the heart related to the blood distribution of the anterior descending coronary artery, though in other instances the inferior wall or the septum (partition) of the ventricle is involved. Coronary thrombosis is present in a majority of the hearts examined at autopsy and undoubtedly plays an important role. In others, changes in metabolic demands of the heart muscle in the presence of a restricted blood flow may be enough to cause death of ischemic cells.

The outstanding clinical feature of myocardial infarction is pain, similar in many respects to that of angina pectoris. The important difference is that the pain lasts for a much longer period, at least half an hour, and usually for several hours and perhaps for days. The pain is described as "crushing," "compressing," "like a vise," and is often associated with some difficulty in breathing. As with angina pectoris, the pain may radiate to the left arm or up the neck into the jaws. There is often nausea, vomiting, and weakness. Fainting (syncope) may occur. The affected person frequently is pale, and he may perspire profusely. Infrequently, these symptoms may be absent, and the occurrence of infarction can then be detected only by laboratory tests. Laboratory studies may show an elevation of the number of white blood cells in the blood or a rise in the enzyme content of the blood, indicating leakage from damaged heart muscle cells. The electrocar-

(C) The same right coronary artery completely unblocked.

diogram in most instances shows distinct and characteristic abnormalities at the onset, but the electrocardiographic abnormalities may be less characteristic or totally absent.

Physical signs of infarction

In most persons who experience an acute myocardial infarction, the circulation remains adequate, and only by subtle evidence such as rales (abnormal respiratory sounds) in the lungs or a gallop rhythm of the heartbeat may the evidence of some minor degree of heart failure be detected. In a small percentage of cases, the state of shock occurs, with pallor, coolness of the hands and feet, low blood pressure, and rapid heart action. In these cases, myocardial infarction is deadly, with survival rates of only 20–40 percent, in contrast to the current survival rate in many hospitals of 80–90 percent. Mortality is also related to age, for the process is more lethal in the elderly. In a small number of persons there may be thromboembolism (obstruction caused by a clot that has broken loose from its site of formation) into an artery elsewhere in the body.

In some individuals, the damage caused by the infarction may interfere with the functioning of the mitral valve, the valve between the left upper and lower chambers, and result in a form of valvular heart disease. It may cause a rupture of the interventricular septum, the partition between the left and right ventricles, with the development of a ventricular septal defect, such as is seen in some forms of congenital heart disease. Rupture of the ventricle also may occur.

Recovery

Drugs are used to control arrhythmias and to strengthen myocardial function. Convalescence from an acute myocardial infarction may last several weeks, allowing time for scar tissue to form in the area of an infarction and a gradual return to activity. Although some persons may have residual evidence of heart failure or other cardiac malfunction, most individuals may return to an active life after a period of weeks and are not in any way invalided by the process. These individuals do, however, have an increased potential for subsequent myocardial infarction.

Sudden death. The term sudden death is used imprecisely and includes death that is almost instantaneous as well as death in which rapidly deteriorating disease processes may occupy as much as two or three days. In heart disease both may occur, but the term characteristically refers to instantaneous death, which is frequent in coronary heart disease. Sudden death from coronary heart disease occurs so frequently that less than half of the persons who die from heart attacks each year in the United States survive long enough to reach the hospital.

Instantaneous cardiac death is usually due to ventricular fibrillation (an uncontrolled and uncoordinated twitching of the ventricle muscle), with total mechanical inadequacy of the heart and erratic and ineffective electrical activity. Sudden death may occur without any previous manifestations of coronary heart disease. It may occur in the course of angina pectoris and causes about one-half of the deaths due to acute myocardial infarction in hospitalized patients, though this number is decreasing with the more widespread use of coronary-care units. Although a reduced supply of blood to the heart undoubtedly is the precipitating factor, acute myocardial infarction does not always occur. In most persons who have died almost instantaneously, no infarction was present, but there was widespread coronary artery disease. In rare instances, sudden death occurs without a major degree of coronary artery disease.

The use of closed-chest cardiopulmonary massage (massage of heart and lungs without making an opening in the chest wall), coupled with electrical defibrillation (the use of electrical shocks), if applied within a few minutes of the sudden death episode, may successfully resuscitate the majority of patients. In coronary-care units where the facilities and trained personnel are immediately available, the percentage of successful resuscitations is high. In general hospitals where resuscitation teams have been established, the percentage is less satisfactory. Sudden death outside the hospital is, of course, a more difficult problem, but mobile coronary-care units responding as emergency ambulances to the site of a sudden death are being used widely and successfully. Effective resuscitation depends upon the prompt arrival of the unit. The use of drugs and other means to prevent the onset of sudden death has been relatively successful in the coronary-care unit, except in situations in which the disease has been present for a long period of time.

Survival during and after a heart attack. The risk of death from an arrhythmia is greatest within the first few minutes of the onset of an occlusion in a coronary artery or of acute ischemia occurring in the region of the myocardium. Thus, of those likely to die during the first two weeks after a major heart attack, 40 percent will die within one hour of the onset and another 20 percent within the next three hours.

Ventricular fibrillation

During the first few hours most persons have some disturbances of rhythm and conduction. Ventricular fibrillation is particularly common in the first two hours, and its incidence decreases rapidly during the next 10 to 12 hours. If undetected, ventricular fibrillation is lethal. It can be reversed, however, in 80 to 90 percent of patients with the use of appropriate electronic devices for monitoring heart rhythm, for giving a direct-current shock to stop it, and for resuscitation.

Both the immediate and long-term outlook of persons after myocardial infarction depends on the extent of myocardial damage and the influence of this damage on cardiac function. Efforts to limit or reduce the size of the infarct have been unsuccessful in improving the short- or long-term outlook. Procedures that cause thrombi to dissolve (thrombolysis), however, have led to the dramatic and immediate opening of apparently occluded coronary arteries. When such measures are implemented within four hours (and preferably one hour) of the onset of the heart attack, the chances of survival are greater, although it has not been shown that long-term prognosis is improved. Naturally occurring lytic enzymes (such as streptokinase) or genetically engineered products are used.

Coronary artery bypass surgery. Coronary artery bypass surgery is widely used to restore adequate blood flow to the heart muscle beyond severe atheromatous obstruction in the main coronary arteries. The most common operation is one in which lengths of superficial veins are taken from the legs and inserted between the aorta, usually above the sinuses of Valsalva, and joined to a part of a coronary artery below the obstructive atheromatous lesion. Multiple grafts are often used for multiple atheromatous occlusions. The internal mammary arteries are also used to provide a new blood supply beyond the point of arterial obstruction; however, since there are only two internal mammary arteries, their use is limited.

There are two principal uses for coronary artery bypass surgery. One is to relieve chest angina that is resistant to medication. The other is to prolong a person's life; however, this is only achieved when all three main coronary arteries are severely obstructed and when the contractility of the left ventricle has been impaired somewhat. Coronary artery bypass surgery does not prolong life when it is used to overcome an obstruction in only one or even two arteries.

Prevention of coronary heart disease. Most physicians recommend the elimination of cigarette smoking, a reduction of dietary saturated fat, a proportional increase in fat calories from polyunsaturated sources, a reduction in high blood pressure, an increase in physical activity, and the maintenance of a weight within normal limits. While the circumstantial evidence from many kinds of studies supporting these measures is impressive, they have not yet been shown to be as effective as expected or predicted. While claims are made that a decrease in the rate of death from heart disease in the United States, Australia, Finland, and other countries is due to such changes in life style, similar changes in life style elsewhere have not been associated with a decrease in the death rate. In some countries (such as Sweden) coronary mortality has actually risen. Those persons, however, who come from high-risk families, such as those with familial hypercholesterolemia, have benefited from reduction of high levels of serum cholesterol. Reduction of high blood pressure, on the other hand, has not been shown to lower coronary mortality.

Rheumatic heart disease. Rheumatic heart disease results from inflammation of the heart lining, heart mus-

cle, and pericardium occurring in the course of acute rheumatic fever, an infection with *Streptococcus pyogenes* organisms. The disease includes those later developments that persist after the acute process has subsided and may result in damage to a valve, which may in turn lead to heart failure.

Rheumatic fever is poorly understood. The disease process occurs days or weeks following the initial streptococcal infection. Later infections may bring about recurrences of the rheumatic fever that damage the heart. Immunologic processes (reactions to a foreign protein) are thought to be responsible for the response that damages the heart and particularly the heart valves. Rapid and effective treatment or prevention of streptococcal infections stops the acute process.

Many other factors of a geographic, economic, and climatic nature influence the incidence of rheumatic fever but are not the primary causes. Rheumatic fever is becoming less common in the second half of the 20th century, and with better control of streptococcal infections, there is an indication of a sharp decline in rheumatic heart disease.

Pathologic changes

It is thought that the basic pathologic lesion involves inflammatory changes in the collagen, the main supportive protein of the connective tissue. There is also inflammation of the endocardium and the pericardium. Only a relatively small percentage of deaths occur in the acute phase, with evidence of overwhelming inflammation associated with acute heart failure. There may be a disturbance of the conduction system of the heart and involvement of other tissues of the body, particularly the joints. About one-half of the persons found to have late rheumatic valvular disease give some indication that they have had acute rheumatic fever.

Major effect of rheumatic fever

The major toll of rheumatic fever is in the deformity of the heart valves created by the initial attack or by frequently repeated attacks of the acute illness. Although there may be valve involvement in the acute stages, it usually requires several years before valve defects become manifest as the cause of heart malfunction. The valve most frequently affected is the mitral valve, less commonly the aortic valve, and least common of all, the tricuspid valve. The lesion may cause either insufficiency of the valve, preventing it from operating in a normal fashion and leading to regurgitation, or stenosis (narrowing) of the valve, preventing a normal flow of blood and adding to the burden of the heart.

Mitral valve involvement is usually symptomless initially but may lead to left ventricular failure, with shortness of breath. Heart murmurs are reasonably accurate signposts for specific valvular diagnoses. A murmur during the diastolic, or resting, phase of the heart, when blood normally flows through the mitral valve to fill the ventricle, generally indicates the presence of mitral stenosis. On the other hand, a murmur during the systole, or contraction, of the left ventricle, indicates an abnormal flow of blood back through the mitral valve into the left atrium (mitral regurgitation). When this latter condition is present, each beat of the heart must pump enough blood to supply the body as well as the wasted reflux into the pulmonary vascular system. This additional work load causes dilation and enlargement of the ventricle and leads to the development of congestive heart failure.

Involvement of the aortic valve is common, and again there may be evidence of stenosis or insufficiency. The presence of aortic stenosis may lead to a marked hypertrophy (enlargement) of the left ventricle of the heart. Involvement of either the tricuspid or pulmonic valve occurs in a similar fashion. In many persons with rheumatic valvular disease, more than one valve is involved. The specific type of valve involved influences the clinical picture of congestive failure (see below *Heart failure*).

The heart, the pulmonary artery, and the aorta. *Pulmonary heart disease (cor pulmonale).* An obstruction to blood flow through the network of vessels in the lungs develops in various types of lung disease. Impingement on blood flow in this integral part of the total path of blood flow through the body places a burden on the right side of the heart, which normally pumps against a low-pressure load with little resistance to blood flow. Pulmonary-artery pressures are normally low compared with those in the aorta.

Acute and chronic

Pulmonary heart disease may be divided into acute and chronic forms. The classic form of acute pulmonary heart disease (acute cor pulmonale) occurs when there is sudden obstruction to the pulmonary blood-flow pattern, as occurs with a massive embolus—a blood clot that has broken loose from its point of formation. This impairs blood flow through the lungs, causes additional reflex changes that add to the heart's burden, and creates an acute form of high blood pressure in the pulmonary arteries, with dilation and failure of the right ventricle. The right ventricle's pumping ability is acutely depressed, and, therefore, the amount of blood available for the left side of the heart is also restricted, so that systemic circulatory failure occurs.

Respiratory symptoms are not prominent, and the disorder in its early stages is not accompanied by edema in the lung. The clinical picture in the more severe form is one of shock, with cold, pale, and clammy skin, low arterial pressure, and high pulse rate. Oxygen transfer in the lungs is severely impaired, and the heart may be acutely dilated. Treatment is with anticoagulant or thrombolytic drugs (such as streptokinase) and oxygen, which relieve the hypoxia (low serum oxygen levels), or in some instances, surgical removal of the obstruction.

Chronic cor pulmonale may be caused by either a form of pulmonary disease, such as chronic bronchitis and emphysema—in which lung tissue is destroyed and replaced with air spaces, causing a loss of pulmonary blood vessels—multiple blood clots in the vessels of the lung, or a primary disorder of the pulmonary blood vessels. The result is a form of heart failure partly based on an obstruction to flow through the pulmonary blood vessels, producing pulmonary arterial hypertension. Cyanosis may be evident, indicating that the arterial blood is not saturated with oxygen. In patients with chronic bronchitis and emphysema, the lack of oxygen or desaturation contributes to pulmonary hypertension. The manifestations of heart failure are present, particularly where there is edema, except that shortness of breath is often due to the underlying lung disease. The right side of the heart is enlarged, the valve sounds from the pulmonic valve may be loud, and there may be electrocardiographic evidence of chronic strain on the right side of the heart. Drugs that dilate the pulmonary blood vessels or relieve the edema and drugs with anticoagulant effects can be useful in the treatment of chronic pulmonary heart disease. However, the course that affords the best chance of remission of symptoms in patients with cor pulmonale due to chronic bronchitis and emphysema includes prompt treatment of infection, termination of smoking, and correction of the lack of oxygen.

Hypertensive heart disease. Arterial hypertension is a disease in which the regulation of blood pressure is abnormal, resulting in arterial pressure that is chronically higher than normal. Hypertension results from several causes, but the cause of the most common form (essential hypertension) is not understood. A family tendency to hypertension has been found in persons with the disease, and there may be a basic genetic abnormality involving altered cell membrane permeability in the blood vessels. This defect might make such persons less able to handle salt and in turn more responsive to hormonal or nervous stimulation.

Causes of hypertension

Excessive dietary intake of salt has long been held to be responsible for hypertension in certain groups, while other groups with a low sodium intake do not show an increase in blood pressure with age. Stress has also been shown to cause hypertension, and fear and anxiety can induce a rise in blood pressure owing to increased activity in the sympathetic nervous system. Other hormones and vasoactive substances have a direct effect on blood pressure, but the interaction of these factors remains unclear. Hypertension also results from a number of types of chronic renal (kidney) diseases and some tumours of the adrenal gland. In certain structural abnormalities of the aorta, such as coarctation, in which the artery's middle coat is deformed with resulting narrowing of the channel, arterial pressure in the upper half of the body is abnormally high.

Regardless of the cause, but in some ways coloured by it, the effects on the cardiovascular system are similar. The impact on the vascular system varies from person to person. In some persons, for unknown reasons, the body withstands the abnormal elevation of blood pressure with minimum change in the heart and blood vessels. In other persons, blood vessel damage is early and severe, coupled with serious deterioration of heart function. In general, the rule is that the higher the blood pressure, the higher the degree of cardiovascular damage, though there are many exceptions. Rarely, a vicious and damaging form of hypertension occurs, often called malignant hypertension, which results in small blood vessel damage throughout the body, but particularly affecting the heart, brain, and kidneys.

Persons with hypertensive disease have an increased susceptibility to atherosclerosis of the coronary arteries, thus making it difficult to separate the cardiac manifestations from those actually caused by hypertension. Hypertensive persons, therefore, may eventually have congestive heart failure following enlargement of the heart caused by chronic increase in arterial pressure. In addition, they may suffer the effects of a decline in blood supply to the heart because of coronary artery disease and the classic manifestations of coronary arteriosclerosis, such as angina pectoris or death of a portion of heart muscle (myocardial infarction). Hypertensive cardiovascular disease may also become manifest through defects in the vessels supplying the brain, leading to stroke or other abnormalities of the brain. Furthermore, hypertensive cardiovascular manifestations may be complicated by the development of kidney failure and resultant abnormal retention of fluid in the tissues, adding to the problems of congestive heart failure.

Before the use of antihypertensive drugs, high blood pressure was associated with a greatly increased mortality, with survival measured in months in the most severe cases. Antihypertensive drugs have dramatically increased the life expectancy of patients with severe hypertension, and heart failure, stroke, and kidney failure are now relatively uncommon in treated hypertensive patients. A similar reduction in coronary heart disease among this group of patients, however, has not occurred. Other factors, such as smoking and diet, may be important in this aspect of therapy. The treatment of mild hypertension is more controversial; although some patients benefit when actively treated as compared with those given a placebo.

Other diseases of aorta and pulmonary arteries. Arteriosclerosis may involve the aorta and its major branches. Indeed, it seems to be an almost inevitable process with increasing age, but the rate of development and the extent of involvement vary greatly. The process may merely limit the elasticity of the aorta and allow for some dilation and tortuosity as age advances. In more severe instances, there may be a major degree of dilation or localized formation of aneurysms (bulging of the vessel wall at a point of weakness), generally in the abdominal portion of the aorta. These aneurysms may result in pain and may occasionally rupture, causing sudden death. The arteriosclerotic process may impair the flow of blood to the tributaries of the aorta and lead to a variety of ischemic states—*i.e.*, result in various types of damage that come from an insufficient supply of blood. This condition is particularly notable when the renal vessels are involved, creating a state of renal ischemia, occasionally creating hypertension, and possibly terminating in renal failure.

Aneurysms of the aorta

Medial necrosis is a lesion of the aorta in which the media, the middle coat of the artery, deteriorates and, in association with arteriosclerosis and often hypertension, may lead to a dissecting aneurysm. In a dissecting aneurysm a rupture in the intima, the innermost coat of the artery, permits blood to enter the wall of the aorta, causing separation of the layers of the wall. Obstruction to tributaries may occur, which is usually associated with severe chest pain. In many instances there is a secondary rupture of the exterior wall, which may lead to fatal internal bleeding. Inflammation of the aortic wall may occur as an isolated process.

Deposition of calcium salts in the aorta wall may occur as a part of the arteriosclerotic process or of other disease involvement. In certain conditions, such as congenital heart disease, blood clots (thrombi) may form in the pulmonary artery, and these may break loose. Blood clots in the lungs (pulmonary emboli) may arise from this and other sources in the systemic venous circulation. These fragments of clot may be small, causing no detectable manifestations, or large, causing obstruction of either the total pulmonary arterial flow or of flow to an area of lung.

Syphilis of the heart and aorta. Syphilis, a disease caused by infection with a microorganism, *Treponema pallidum,* in its early phases becomes widespread in the human body. At this time there may be transient inflammation of the heart muscle, but usually with little or no impairment of the circulation. In the late stages of the disease there may be syphilitic involvement of the heart, confined almost purely to the aorta and aortic valve. A particularly severe form of aortic insufficiency may develop, with subsequent dilation and enlargement of the heart and, eventually, heart failure. The disease process often involves the base of the aorta and the blood flow through the openings into the coronary vessels from the aorta, causing impairment of the coronary circulation, with resultant angina pectoris and, on rare occasions, myocardial infarction, the death of portions of heart muscle.

Areas of involvement

The syphilitic process may also involve the wall of the aorta, resulting in the loss of the elastic properties, in dilation, and, at times, in the formation of aneurysms of the aorta. The aneurysms may become large and interfere with blood flow through the tributaries of the aorta in the involved area. They may be the source of pain and eventually may rupture, causing sudden death from loss of blood into the thoracic cavity. Syphilis of the aorta was common in the past, but with the advent of more modern control mechanisms, plus effective early treatment with the use of penicillin, the disorder has become much less common. Late complications can be effectively avoided by early antisyphilitic treatment.

Diseases of the endocardium and valves. Bacterial endocarditis, a disease in which bacterial or fungus infection becomes established on the surface of a heart valve or, less commonly, in a blood vessel wall or in the endocardium of the heart, usually occurs where there has been some previous lesion, either congenital or acquired. Most frequently, the location is at the line of closure of the valve. The disease may be acute and severe, or it may be a more chronic situation, often referred to as subacute bacterial endocarditis. It may erode the valve structure, or it may be of an inflammatory nature, producing nodules with the ulcerative surface of active infection. Because the bacteria are embedded in the lesion, the normal body defenses contained in the blood have difficulty entering into play; for this reason, certain types of bacterial endocarditis become more chronic and more slowly progressive. The effects of the lesion are complex, being related to the presence of a bacterial infection in the body, local damage to the valve, and systemic damage caused by fragments of a blood clot that breaks off and travels through the bloodstream to distant organs. These clots cause infarctions or abscesses, a type of kidney disease, or other small areas of bleeding and necrosis in the skin, eyes, and other parts of the body.

Endocarditis

Before the advent of antibiotic therapy, bacterial endocarditis was almost always a fatal disease. Many affected persons can now be successfully treated, given the best conditions, though the mortality rate still remains relatively high. Inflammation of the heart lining, endocarditis not caused by infection, may occur in some illnesses, but it does not result in formation and breaking loose of blood clots.

In the course of rheumatoid arthritis, a chronic inflammation of the joints of unknown cause, a type of valvular damage has been recognized. It is different from that caused by rheumatic fever but leads to valvular insufficiency and stenosis (narrowing) in much the same fashion and is particularly likely to attack the aortic valve. The tendencies toward heart failure and toward impairment of heart function are the same as in rheumatic valvular disease.

Diseases of the myocardium. There has been increasing recognition of a type of heart disease characterized as primary myocardial disease. The cardiomyopathies are

diseases involving the heart muscle itself. They are unique in that they are not the result of hypertensive, congenital, valvular, or pericardial diseases and are rarely the result of ischemic heart disease. This form of heart disease is often sufficiently distinctive, both in general symptoms and in patterns of blood flow, to allow a diagnosis to be made. Increasing awareness of the condition, along with improved diagnostic techniques, has shown that cardiomyopathy is a major cause of morbidity and mortality. In some areas of the world it may account for as many as 30 percent of all deaths due to heart disease.

Some cardiomyopathies are primary because the basic disease process involves the myocardium rather than other cardiac structures and because the cause of the disease is not known and not part of a disorder of other organs. Other cardiomyopathies are conditions in which the cause of the myocardial abnormality is known and the cardiomyopathy is a manifestation of a systemic disease process. Clinically, the cardiomyopathies fall into three categories: dilated cardiomyopathy, characterized by ventricular dilation and often symptoms of congestive heart failure; hypertrophic cardiomyopathy, characterized by hypertrophy of the ventricle, particularly the left ventricle; and restrictive cardiomyopathy, marked by scarring of the ventricle and impairment of filling in diastole.

A large number of cardiomyopathies are apparently not related to an infectious process but are not well understood. A number of these are congenital and many cause enlargement of the heart. About one-third of these diseases are familial, and some of these are transmitted as a non-sex-linked autosomal dominant trait (*i.e.,* a person may be affected if he inherits the tendency from one parent). They are particularly common among black populations. A number of metabolic diseases associated with endocrine disorders may also cause cardiomyopathies. Other metabolic disorders that may contribute to cardiomyopathy include beriberi, caused by a nutritional deficiency; cobalt poisoning in heavy beer drinkers; or a form of cardiomyopathy in chronic alcoholics. There are also rare cardiomyopathies caused by drugs. Infections, such as acute rheumatic fever and several viral infections, may cause any of a number of types of myocarditis. Myocarditis may also occur as a manifestation of a generalized hypersensitivity (allergic or immunologic) reaction throughout the body.

The cardiomyopathies may cause no symptoms and may be detected only by evidence of an enlarged heart and disturbances in cardiac conduction mechanisms detected on electrocardiography. In other instances, extensive involvement may lead to heart failure. Some cases may be chronic, with exacerbations and remissions over a period of years.

The collagen diseases

The heart may be affected by any of a considerable number of collagen diseases. Collagen is the principal connective-tissue protein, and collagen diseases are diseases of the connective tissues. They include diseases primarily of the joints (*e.g.,* rheumatoid arthritis); primarily of the skin (*e.g.,* scleroderma); and systemic disease (*e.g.,* systemic lupus erythematosus).

Diseases of the pericardium. Pericardial disease may occur as an isolated process or as a subordinate and unsuspected manifestation of a disease elsewhere in the body. Acute pericarditis—inflammation of the pericardium—may result from invasion of the pericardium by one of a number of agents (viral, fungal, protozoal); as a manifestation of certain connective tissue and allergic diseases; or as a result of chemical or metabolic disturbances. Cancer and specific injury to the pericardium are also potential causes of pericardial disease.

Pain is the most common symptom in acute pericarditis, though pericarditis may occur without pain. A characteristic sound, called friction rub, and characteristic electrocardiographic findings are factors in diagnosis. Acute pericarditis may be accompanied by an outpouring of fluid into the pericardial sac. The presence of pericardial fluid in excessive amounts may enlarge the silhouette of the heart in X rays but not impair its function. If the pericardial fluid accumulates rapidly or in great amounts, if there is a hemorrhage into the sac, or if the pericardium is diseased so that it does not expand, the heart is compressed, a state called cardiac tamponade. There is interference with the heart's ability to fill with blood and reduction of cardiac output. In its more severe form, cardiac tamponade causes a shocklike state that may be lethal. Removal of the fluid is lifesaving in an emergency and aids in the identification of the cause.

Cardiac tamponade

Chronic constrictive pericarditis, caused by scar tissue in the pericardium, restricts the activity of the ventricles. In many instances, the cause is not known, but in some it is the result of tuberculosis and other specific infections. It is treated most effectively by surgery. Tumours that either arise directly from the pericardium or are secondary growths from other sources may impair cardiac function and cause pericardial effusion (escape of fluid into the pericardium).

DISTURBANCES IN RHYTHM AND CONDUCTION

The heart's rhythmical beat is initiated and regulated from centres within the organ. The primary pacemaker, the sinoatrial node, is a small mass of specialized muscle cells located at the juncture of the upper vena cava and the right atrium. Electrical impulses are emitted by this group of cells. The excitation spreads through the two atria and, by way of a band of fibres called the bundle of His, into the ventricles. The bundle of His has its beginning in a small mass of cells, the atrioventricular node, located beneath the lining of the right atrium.

Normally initiated heart rhythm, originating in the sinoatrial node, is called sinus rhythm. Under stimulation from the central nervous system and other metabolic factors, heart rate may normally rise and fall, with a slight variation, in part related to respiratory activity. In young individuals in excellent physical condition, the resting heart rate may fall as low as 40 to 50 beats per minute, and, under stressful psychological stimulation, the heart rate may rise to as high as 200 beats per minute. These situations are to be differentiated from pathological variations in heart rate. Abnormal slowing of heart rate, or sinus bradycardia (a slow sinus rhythm with a rate below 60, caused by disturbance of the sinoatrial node) or acceleration of heart rate, or tachycardia (excessive rapidity in the action of the heart with a pulse rate of above 100 beats per minute) may occur in a wide variety of disease states and be symptomatic of the underlying disease.

Extra beats arising from the atrium, the nodal tissues, or the ventricle are not in themselves abnormal, though beats arising from the ventricle are more often associated with organic heart disease. Occasional extra systoles (contractions) occur in many normal individuals. In cardiovascular disease they are much more common. They do not interfere with normal cardiovascular function if infrequent. It has been noted that continued psychological stress, excessive smoking, and drinking of large amounts of tea and coffee enhance the tendencies for premature contractions of the atria. Premature contractions of the ventricles are more ominous, especially those that occur after exercise. They have been found to be associated with coronary artery disease in a large percentage of instances. If frequent enough, they may be the harbinger of more serious ventricular arrhythmias.

Atrial arrhythmias. Abnormalities in the rhythm of atrial contractions include atrial tachycardia, atrial flutter, and atrial fibrillation. As noted earlier, atrial tachycardia may be a manifestation of underlying disease such as thyrotoxicosis or may be merely a matter of stressful stimulation in a normal individual. Some individuals have characteristic episodes of paroxysmal atrial tachycardia of varying frequency and duration, with a rapid onset and termination. Ordinarily the episodes occur in the absence of any other heart abnormality. Occasionally, especially when the episodes are prolonged or when they occur in the presence of organic cardiovascular disease, they may be accompanied by evidence of heart failure or, in rare instances, of the shock state.

Atrial flutter and fibrillation

Atrial flutter represents another form of arrhythmia associated with very rapid atrial activity. The atrial activity is regular but so rapid that the conduction of the impulses to the ventricle may be delayed and impaired so that

only one of two, three, or four impulses excite ventricular activity. This disorder is most often, but not always, seen in persons with organic heart disease.

Atrial fibrillation is another form of arrhythmia, in which there is wildly erratic and ineffective atrial contraction. The ventricular response is also erratic, so that the pulse is irregular without a basic underlying rhythm. This disorder is seen most frequently in persons with organic heart disease, such as rheumatic heart disease with mitral involvement and thyrotoxicosis, but also occurs in normal individuals, often on a paroxysmal basis. It renders the atrium ineffective, and therefore the contribution of this chamber to the normal pumping of blood is negated. This condition may be of no real functional importance in the normal heart but may have a significant detrimental effect in the failing heart. The circulation functions reasonably well, though in the case of severe mitral stenosis a rapid heart action is not well tolerated because of the limited speed of ventricular filling through a small mitral opening.

A complication of atrial fibrillation is the development of blood clots within the walls of the fibrillating atria. Because these clots may eventually fragment and pass into the circulation (arterial embolism), atrial fibrillation is a condition that should be treated if possible. The abnormal rhythm may be slowed by digitalis or terminated by the use of electrical shocks (electrical defibrillation).

Atrioventricular node mechanisms. Normally, the impulse for ventricular contraction arises from a focus in the atria, passes through the atrioventricular node and bundle of His, which delay progression, and then excites ventricular activity. This mechanism may not operate properly in various pathological states. In some instances, more rapidly firing (*i.e.,* impulse-emitting) tissue in the atrioventricular node may initiate the ventricular activity, supplanting the normal atrial focus and resulting in tachycardia, called nodal tachycardia because of the part played by the atrioventricular node. More frequently, the abnormal mechanism is one of delay or obstruction in progression of the impulse, creating "heart block," a lack of synchronization between atria and ventricles; there may be varying degrees of severity. In first-degree heart block, there is merely a short delay over the normal conduction time from the atrium to the ventricle. This condition does not result in clinical manifestation but is detected electrocardiographically by a longer than normal period of time between the P wave, which is associated with atrial activity, and the QRS complex, which is associated with ventricular excitation.

Three degrees of heart block

In a more severe (second-degree) form, the impulse may travel relatively normally through the conduction system, but some beats are blocked. Alternate beats may be blocked, resulting in what is known as a two-to-one heart block, or the ratio may be three-to-one, four-to-one, etc. The degree of blockage of conduction may be influenced by stimulation from outside the heart, such as from the carotid sinus or the central nervous system, and is dependent in part on drug action. (The carotid arteries are the principal arteries to the head. The carotid sinus, located at the fork where the common carotid divides into the external and internal carotid arteries, is an important structure for monitoring and regulating blood pressure.)

The conduction system below the atrioventricular node divides into two major branches, to the two ventricles, and, therefore, blockage of impulse transmission in either of these is termed right or left bundle branch block. This condition is identified by electrocardiographic changes and is most frequently associated with organic heart disease, though it may occur rarely in normal individuals.

The most severe form of heart block, complete heart block, is characterized by total dissociation of atrial activity and ventricular activity. In this situation, atrial activity usually continues at a normal or higher than normal rate. Independently the ventricle establishes its own rate, usually slower than normal, but in some instances within the normal range. If the latter is the case, the difficulty is without major consequence on the circulation. More frequently, however, it is at a slower rate, and there may be some resultant inadequacy of the circulation. This condition is usually associated with forms of organic heart disease, and the slowness of the rate may precipitate congestive heart failure or other manifestations. It may be treated by the use of drugs or electrical pacemakers to increase the rate of ventricular activity.

At times, the degree of heart block or its occurrence may be variable and erratic. This condition may result in considerable pauses in left-ventricular depolarization and contraction, the basic mechanism that precipitates the Adams-Stokes syndrome, which leads to occasional episodes of unconsciousness. (The syndrome is named for the Irish physicians Robert Adams and William Stokes, whose descriptions of the disease are celebrated.)

Ventricular arrhythmias. The ventricle may respond regularly or erratically to atrial or nodal (atrioventricular) disturbances of rhythm. In addition, it is subject to other intrinsic forms of abnormal rhythm. In the course of severe heart disease, such as coronary artery disease, ventricular tachycardia (fast beating of the ventricles) may occur. The beat is regular but may be so rapid that it interferes with normal cardiac filling and ejection and, therefore, results in either congestive failure, if prolonged, or in the development of a shock state, if severe and acute. Ventricular tachycardia is perhaps most important because it may be the forerunner of ventricular fibrillation, in which, as in atrial fibrillation, the contractions are widely erratic and ineffective, so that ventricular fibrillation interferes so much with ventricular function that circulation of the blood effectively ceases. Unless reversed within seconds or minutes, it is lethal. The recognition of ventricular tachycardia and fibrillation has been the basis for the success of modern coronary-care units. It is treatable either by drugs or, more frequently, by the use of external electrical defibrillation, the application of electrical shocks.

Ventricular tachycardia and fibrillation

Some of the major recognized forms of arrhythmia have been presented. There are many special variants on this pattern, but even with the most complex electrocardiographic studies, some arrhythmias defy explanation.

HEART FAILURE

Congestive heart failure, a syndrome resulting from disease that has caused the heart to be inadequate as a pump, is characterized by manifestations distant from the heart, predominantly related to salt and water retention in the tissues. It may vary from the most minimal symptoms to sudden pulmonary edema (abnormal accumulation of fluid in the lungs) or to a rapidly lethal shocklike state. Chronic states of varying severity may last years. The symptoms are related predominantly to secondary manifestations resulting from retention of fluid and vascular congestion throughout the body, rather than to the direct effect of lessened blood flow. In most instances, failure results from a diseased heart, though on occasion the burden of other systemic diseases may exceed the capacity of the previously adequate heart and produce the condition.

A physiological characteristic of the normal heart is its ability to meet the fluctuating demands of the body for blood flow. The diseased heart may no longer be able to respond in this way. This failure may be the result of severe and acute damage, such as an acute myocardial infarction, or of chronic and lesser impairment, such as scarring of a valve in the course of a long-standing rheumatic heart disease.

The possible causes of the underlying heart disease are numerous. One is coronary heart disease that has resulted in profound myocardial damage. Other common causes are rheumatic valvular disease, hypertensive vascular disease with involvement of the heart, or one of the multitudinous but less common types of primary disease of the myocardium. Regardless of the cause, the common denominator leading to heart failure is altered function of the heart muscle, with lessened ability to pump blood. In many sophisticated studies, clear-cut disturbances in the mechanics of heart muscle contraction have been demonstrated.

The presence of cardiac failure becomes apparent largely by signs and symptoms not directly related to the heart. With early and untreated heart failure, the person usually has a normal salt and water intake, but his ability to regulate and promptly excrete excess sodium and water is

impaired. The nature of this impairment is not entirely clear. Salt and water accumulate in the body as extracellular fluid that manifests itself as clinically detectable edema. If the person is active and in the upright position, the fluid may gather particularly about the ankles and legs. If he is in bed, it may accumulate in the back, overlying the sacrum. In heart failure, there may also be low blood sodium levels.

Left ventricular failure. The pulmonary circuit (the blood vessels in the lungs) usually becomes congested in heart failure, because heart diseases most frequently affect the left ventricle in one way or another. If disease impedes the left ventricle's pumping of blood into the systemic circulation, the left side of the heart is unable to receive the normal flow of oxygenated blood from the lungs; consequently there is back pressure, and blood accumulates in the lung's blood vessels. If this congestion of the pulmonary vessels occurs, it lessens the amount of space available in the lungs for air and tends to stiffen the lungs. Finally, pulmonary capillary pressure may reach the point at which fluid flows into the tissues outside the vessels, a condition called pulmonary edema. These phenomena account for the frequency of difficulty in breathing, inability to breathe except in an upright position, attacks of respiratory distress without apparent cause during sleep at night (paroxysmal nocturnal dyspnea), and other respiratory symptoms in congestive heart failure.

Effect on the lungs

Pulmonary edema. Acute pulmonary edema developing in the course of heart failure may be severe, occasionally even fatal. It occurs particularly in such situations as arterial hypertension and aortic valve disease. Peripheral edema may or may not be present. This combination of events is often called left heart failure.

Right heart failure. In heart disease affecting primarily the right side of the heart, such as cor pulmonale or disease of the tricuspid valve, between the right atrium and right ventricle, the effect on respiration may be less, and there is greater evidence of edema, congestion of the liver, and high pressure in the veins. Although actually the circulation as a whole is failing, those factors that produce manifestations in the lungs are not prominent.

Incipient heart failure. A person affected rarely speaks of symptoms that can be directly related to the inadequacy of cardiac output. In severe and chronic heart failure, there may be a general deterioration of the body with a form of general ill health and malnutrition that simulates that seen in cancer. There is rarely evidence that blood flow is insufficient to provide adequate tissue function except in the shock state that occurs in acute and severe heart failure, in which there is acute inadequacy of flow to some critical tissues. Although heart failure may occur in certain circumstances, such as severe anemia, in which there is a high cardiac output, in general, heart failure occurs when the cardiac output is reduced from the normal value for the particular person. The inadequacy of the heart may not be constant but may occur, especially in early heart failure, only under the stress of exercise.

Persons in the early stages of heart failure may have no circulatory impairment, though the heart may be dilated or enlarged. Such persons may eventually be unable to respond to stressful situations that demand a high cardiac output. Difficulty in breathing may occur during exertion, but usually edema is not present.

Mild to moderate congestive heart failure. The person with mild to moderate congestive heart failure may have a heart that has an adequate pumping function for the demands at rest but that is unable to meet circulatory needs under stress. Such a person may experience difficulty in breathing during exertion and other early manifestations of heart failure, and these symptoms may even be present to a limited degree at rest. In those situations affecting primarily the left ventricle, episodes of paroxysmal nocturnal dyspnea indicating temporary inadequacy of the left ventricle may be present. There may be mild edema of the ankles at the end of the day. The manifestations are not severe or grossly disabling. As the condition becomes more severe, increasing frequency of difficulty in breathing (dyspnea) and greater amounts of edema may be present.

The degrees of heart failure

Severe congestive heart failure. Heart failure may become totally disabling, with severe respiratory distress and inability to lie flat and to exercise. Gross edema including abnormal amounts of fluid in the abdomen (ascites) and in the chest cavity (hydrothorax) is present. When such circumstances are prolonged, general body deterioration may develop, with various secondary effects, such as appetite loss or diarrhea.

Cardiogenic shock. A degree of heart failure from mild to severe may occur after acute and severe cardiac damage, such as an acute myocardial infarction. In some instances, this condition may progress to a shocklike state, with such classic manifestations as low blood pressure, a rapid, thready (thin) pulse, and pallor, a condition known as cardiogenic shock. It may or may not be accompanied by respiratory symptoms or evidence of edema. No edema from congestion in the peripheral vessels develops if the condition is of short duration, but acute pulmonary edema may be experienced. (J.V.W./M.F.O.)

SURGICAL TREATMENT OF THE HEART

Cardiopulmonary bypass. Cardiopulmonary bypass serves as a temporary substitute for a patient's heart and lungs during the course of open-heart surgery. The patient's blood is pumped through a heart-lung machine for artificial introduction of oxygen and removal of carbon dioxide. Before its first successful application to operations on the human heart in the early 1950s, all heart operations had to be done either by the sense of touch or with the heart open to view but with the patient's whole body held to a subnormal temperature (hypothermia). The latter procedure was feasible only for very brief periods (less than five minutes).

The oxygenator

The first heart-lung machine (pump oxygenator) resembled only slightly the complicated apparatus currently used for correction of cardiac defects. With this machine the blood bypasses the heart and lungs so that the surgeon has an unobstructed view of the operative field. Cardiopulmonary bypass is accomplished by use of large drainage tubes (catheters) inserted in the superior and inferior venae cavae, the large veins that return the blood from the systemic circulation to the right upper chamber of the heart. The deoxygenated blood returning to the heart from the upper and lower portions of the body enters these tubes and by gravity drainage flows into a collecting reservoir on the heart-lung machine. Blood then flows into an oxygenator, the lung component of the machine, where it is exposed to an oxygen-containing gas mixture or oxygen alone. In this manner, oxygen is introduced into the blood and carbon dioxide is removed in sufficient quantities to make the blood leaving the oxygenator similar to that normally returning to the heart from the lungs.

From the oxygenator, blood is pumped back to the body and returned to the arterial tree through a cannula (small tube) introduced in a major systemic artery, such as the femoral (groin) artery. Oxygenated blood then flows to the vital organs, such as the brain, kidneys, and liver. Meanwhile, the heart may be opened and the corrective operation performed. This procedure permits a surgeon to operate on the heart for many hours, if necessary.

The assemblage and sterilization of the components of the heart-lung machine are essential considerations because the blood comes in contact with the apparatus outside of the body. Heart-lung machines have totally disposable tubing and plastic bubble oxygenators. Cardiopulmonary bypass is now more often carried out by using cardioplegic solutions designed to provide the heart with the necessary minimal nutrient and electrolyte requirements. Blood is also needed, and administration of an anticoagulant (heparin) prevents clotting of the blood while it is circulating in the heart-lung machine.

Congenital cardiac defects. Most congenital cardiac defects can be repaired surgically. Operations are of two general types: those that can be performed without a heart-lung machine, such as surgeries for patent ductus arteriosus and coarctation of the aorta; and those, such as intracardiac abnormalities, that require a heart-lung machine.

Persistent (patent) ductus arteriosus. The ductus arteriosus is the channel in utero between the pulmonary artery and the first segment of the descending thoracic

aorta. Before birth, blood flows from the right ventricle into the pulmonary artery and across the ductus arteriosus to the descending aorta. The ductus shunts blood away from the lungs because oxygen–carbon dioxide exchange begins only at the time of birth. Normally functional closure of the ductus arteriosus is completed within the first few days after birth, although complete anatomic closure may not occur for several months. If it remains open, excessive levels of blood may flow through the lungs.

First surgery for congenital heart disease

Ligation of the ductus arteriosus performed by Robert E. Gross in Boston in 1938 was the first successful operation for congenital heart disease and initiated the modern era of cardiac surgery for congenital cardiovascular lesions.

Coarctation of the aorta. Coarctation of the aorta, which is a constriction of the aorta, usually in the same region as the ductus arteriosus, is one of the most common congenital cardiac defects. It was first successfully repaired by Clarence Crafoord in Sweden in 1944. In older children and adolescents the narrowed area is repaired by cutting out the constriction and stitching the two normal ends together. In infants, a modified operation is used in which the left subclavian artery (the artery that supplies the left arm) is tied, divided, and used as a flap to repair the narrowed aortic area. With this procedure the stricture has less of a tendency to redevelop at that site. In adults it often may be necessary to bridge the narrowed area with a graft tube, which is attached to the aorta above and below the narrowed segment; the blood is thus able to bypass the constricted area to reach the organs below the defect.

Pulmonary valve stenosis. The most common congenital defect of the valves in children is a narrowing of the pulmonary valve (the valve opening to the pulmonary artery). The valve cusps in this condition are not well formed and, as a result, the valve cannot open normally. The valve cusps are thickened, and the size of the orifice varies in diameter from one millimetre to about two-thirds of that of the circumference of the pulmonary artery. As a result blood flow from the right ventricle into the lungs is obstructed. Mild stenosis is usually compatible with normal activities and normal life, but moderate and severe stenosis may result in clear symptoms.

The surgical procedure used to correct this condition is usually performed on cardiopulmonary bypass, with the valve approached through the pulmonary artery and cut in three places to create a valve with three cusps. An alternative approach to surgery is the use of a special balloon catheter, which is passed from the femoral vein (the vein in the groin) into the right side of the heart and positioned across the pulmonary valve. A balloon at the tip of the catheter is then inflated to enlarge the valve orifice.

Aortic valve stenosis. Although mild aortic valve stenosis is manageable in children, deterioration may occur with growth. Severe aortic stenosis in infancy and childhood may be associated with either sudden death or heart failure. The usual basis for the stenosis is fusion of the valve, which is usually bicuspid rather than tricuspid. The valve is often both obstructed and incompetent (allowing blood to leak back from the aorta into the left ventricle). Patients with more than a trivial degree of aortic stenosis usually should not take part in competitive sports such as swimming or football. In moderate to severe degrees of aortic stenosis, surgery usually is necessary and is performed using cardiopulmonary bypass. The aorta is opened just above the valve, and the surgeon incises the valve sufficiently to convert severe stenosis to a mild or moderate degree of obstruction. In older patients the valve is often thickened and calcified, and it may need to be replaced.

Atrial and ventricular septal defects. If atrial and ventricular septal defects require surgical closure, the patient's circulation must be supported by the heart-lung machine.

Septal repairs

Atrial septal defects are usually repaired by sewing the tissue on either side of the defect together, although very large defects may require a patch of material to close the opening. Because of the frequency of spontaneous natural closure, small ventricular septal defects are observed for a period of time before the decision is made to perform surgery. Large ventricular septal defects are usually closed by a patch.

Cyanotic cardiovascular abnormalities. The first attempt to treat "blue babies" affected with cyanotic abnormalities was performed by the American physicians Alfred Blalock and Helen B. Taussig in 1944. This procedure transformed the outlook for cyanotic children and for the first time made survival possible. In the early 1950s, heart-lung cardiac surgery and procedures definitive for repair were developed. Surgical treatment of the tetralogy of Fallot has been an important model for developments in more complex forms of cardiac surgery, and long-term results have been excellent. Most, but not all, forms of cyanotic congenital heart disease can now be repaired, and palliative surgery may produce considerable benefits for those in whom definitive treatment is not possible.

Acquired heart defects. *Valvular disease.* Destroyed heart valves can be replaced with artificial valves (prostheses) made of stainless steel, Dacron, or other special materials. The heart-lung machine is used during these operations, in which one, two, or even three cardiac valves may be removed and replaced with the appropriate artificial valve. The use of both homograft valves (obtained from human beings after death) and heterograft valves (secured from animals) is widespread. One of the advantages of both types is the absence of clotting, which occurs occasionally with the use of artificial valves. Most homograft and heterograft valves have a durability of 10–15 years. There is a risk of endocarditis with all types of values.

Chronic constrictive pericarditis. Chronic constrictive pericarditis can affect the surface of the heart and the sac (pericardium) surrounding it. The pericardium becomes thickened and fibrotic, and over a period of time constricts the heart so that the normal filling of the ventricles during the resting phase of the cardiac cycle is limited. This condition in turn reduces the output of the heart and eventually affects all the organ systems, including the brain, liver, and kidneys. Treatment is surgical removal of the thickened pericardium around the heart, which permits normal filling and expansion of the ventricles and restores adequate cardiac output to the vital organs.

The pericardium

Cardiac pacemakers. The normal rhythm of the heart is generated by spontaneous electrical activity in cells in an area of the heart called the sinoatrial node. The electrical activity is usually at a rate of about 70 beats per minute at rest and is transmitted to the pumping chambers of the heart, the atria, and the ventricles through a specialized conducting system. The electrical activity causes contraction of the heart muscle, which results in a detectable pulse at the wrist and elsewhere. Disease of the sinus node (sick sinus syndrome) or the conducting system (heart block) can cause an abnormally slow rhythm of the heart; because blood supply to the brain is inadequate, severe disease can cause loss of consciousness. This occurs if there is no heartbeat for about six seconds.

Sick sinus syndrome and heart block

A pacemaker is a device that artificially stimulates the heart when the abnormal electrical activity is absent. A pacemaker comprises a pulse generator connected to the heart by wire or electrode. The pulse generator has a battery power source and electronic circuitry that can generate an artificial stimulus at a predetermined rate. It can also detect normal activity of the heart so that the artificial stimulus is only discharged when the natural activity is absent. In this way the pacemaker functions on demand, inserting an artificial beat as required.

The pulse generator is usually placed under the skin over the right or left chest and has enough power to last several years. The electrode is passed from the pulse generator along a vein and is connected to either the atrium or ventricle, depending on whether the underlying problem is sick sinus syndrome or heart block. In many models the performance of the pacemaker can be altered by using radio frequency signals to alter its programmed settings. Some pacemakers may last up to 15 years and can be reused; the most common lifetime is seven years.

Heart arrest. Cessation of the heartbeat, in addition to occurring in heart block, may occur in numerous other circumstances and require emergency treatment. Until the early 1960s, when the heart stopped (cardiac arrest) the chest was opened, frequently with a penknife or any other available instrument, and the heart was massaged with

the hands until beating resumed. Closed cardiac massage now is commonly used, whereby pressure is applied to the breastbone (sternum) directly over the heart. The sternum is compressed intermittently about 60 times a minute while the lungs are expanded with oxygen. Persons may be kept alive with normal blood pressure and circulation for hours by this method. With an adequate airway or when mouth-to-mouth breathing is used, closed cardiac massage is so effective that many laymen are trained in its use for emergency support of circulation.

Heart wounds. Heart wounds are caused by blunt or penetrating instruments. Rapid deceleration, often experienced in automobile accidents, is a common cause of injury to the heart muscle, resulting in bruising and even disruption of a valve or the ventricular septum. Both bullet and stab wounds account for many patients treated in the emergency clinics of major hospitals. Prompt diagnosis and effective surgical treatment, usually consisting of control of bleeding by sewing the heart muscle at the point of entry of the foreign object, have resulted in a high rate of successful treatment.

Provision of new blood supply to the heart

Coronary arterial disease. Operations have been devised to bring a new blood supply into the heart when the coronary arteries become narrowed by atherosclerosis. A commonly used technique is to use a vein removed from the leg as a bypass around the diseased portion (Figure 23). The vein is attached to the aorta above as it leaves the left ventricle. The other end of the vein is then sutured directly to any one of the coronary arteries. Large quantities of blood can be delivered to the heart muscle by this direct form of myocardial revascularization. Implantation of an artery below the breastbone (internal mammary artery) into a coronary artery beyond the block is increasingly used.

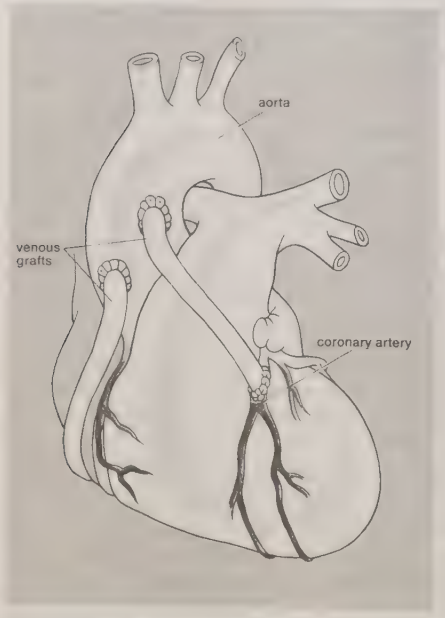

Figure 23: Restoration of blood supply to heart muscle. The vessels shown in white are venous grafts leading from the aorta to coronary vessels.

Carbon dioxide endarectomy is also performed. In this operation, carbon dioxide, which in the bloodstream is readily absorbed and does not cause blockage of the small vessels, is injected directly into the obstructed coronary artery. The gas tends to loosen the inner atheromatous core from the outer adventitial wall of the artery. The atheromatous core is then totally removed, and blood flow is restored through the artery. The heart-lung machine is used to support the circulation during most operations on the coronary arteries.

Angioplasty. The development of catheters with strong inflatable balloons constructed toward their end and along the line of the catheter has greatly changed cardiac surgery. The balloons can be inflated by compressed air at different controlled pressures. They are used for dilation of a partly obstructed coronary artery (percutaneous transluminal coronary angioplasty, or PTCA), with restoration of blood flow to the heart muscle, and of a severely obstructed heart valve, particularly the aortic valve, relieving the pressure on the left ventricle.

The procedure generally requires no anesthetic and, using specialized radiological imaging techniques, is sometimes done on an outpatient basis. Several coronary arteries may be dilated in this way, with flattening of the atheromatous material against and into the arterial wall. Although there are operative risks, such as emboli and tearing, the results are excellent and the technique may be repeated, if necessary.

Heart transplantation. If the heart muscle has been damaged beyond surgical repair, heart transplantation may be performed. The diseased heart is removed and the donor's heart is sewn in position. This procedure is particularly useful in advanced cardiomyopathy. Half of all heart transplant patients survive five years after the surgery. Heart-lung transplants are used for some intractable cardiopulmonary diseases, such as cystic fibrosis. The success rates of both of these operations has grown.

Artificial heart. Many scientists are directing their efforts toward development of an artificial heart. The heart-lung machine effectively supports the circulation for a few hours; if it is used for longer periods, the blood is damaged by the pumping and oxygenation. Current research is directed toward development of pumps and oxygenators that can be used for partial or total support of the circulation for long periods without damage to the blood.

Partial cardiac assistors have been used successfully to aid the heart after operation until it has had sufficient time to recover. One of these is the left ventricular bypass pump. It reduces the work load of the heart because blood is removed from the left atrium of the heart and pumped back to the body through the axillary artery. No oxygenator is required because the lungs are not bypassed.

(M.E.DeB./E.B.D./M.F.O.)

DISEASES OF THE ARTERIES

There are many types of arterial disease. Some are generalized and affect arteries through the body, though often there is variation in the degree they are affected. Others are localized. These diseases are frequently divided into those that result in arterial occlusion (blockage) and those that are nonocclusive in their manifestations.

Occlusive disease. *Arteriosclerosis.* The various types of arteriosclerosis are by far the most common occlusive diseases of the arterial system and a major cause of death in one form or another. Atherosclerosis of the coronary arteries has already been discussed. Arteriosclerotic lesions of the cerebral vessels may lead to formation of blood clots and stroke.

Medial (Mönckeberg's) arteriosclerosis is the condition affecting the media (middle coat) of the main arteries. There are deposits of calcium salts in the media, but in general the channel (lumen) is not blocked. This disease is quite common and may contribute to the other major form of widespread arteriosclerosis, atherosclerosis obliterans, in which there is complete obliteration of the vessel channel.

Intermittent claudication

The classic symptom of arteriosclerosis affecting the legs is called intermittent claudication (intermittent lameness), which results from inadequate blood flow to the muscles involved in walking. In such individuals a cramplike discomfort associated with a limp occurs in the calf of the leg on exercise and is relieved by rest. The vascular disease may lead to changes in the extremities caused by reduced blood supply. These may be manifested as ulcerated areas and eventually gangrene, and most frequently involve the lower extremities. The lack of adequate blood flow renders the extremities susceptible to infection, and, therefore, the manifestations of reduced blood supply (ischemia) are frequently combined with those of infection. There is no specific therapy available.

Thromboangiitis obliterans (Buerger's disease). Thromboangiitis obliterans is a disease of an inflammatory nature, poorly understood, that involves the arteries of the extremities, though other vessels, including those of the heart, may be involved. It is thought to be a disease of

hypersensitivity, and the persons who are afflicted with it are often heavy cigarette smokers. It almost exclusively affects men of any race between the ages of 17 and 45 years. The symptoms are similar to those of arteriosclerosis of the peripheral vessels, with intermittent claudication, later pain during periods of rest, and eventually gangrene. An inflammation of the veins, phlebitis, occurs in almost 50 percent of those affected.

Effects of polyarteritis nodosa

Polyarteritis nodosa. Polyarteritis nodosa, also called periarteritis nodosa, is an uncommon disease of unknown cause; hypersensitivity may play an important role. It is more common in males and may occur at any age. Small arteries and veins in various parts of the body are affected, producing effects as a result of occlusion or bleeding or a combination of the two. The course may be rapid, involving only weeks or months, or it may be highly prolonged. The involvement of the blood vessels may affect blood flow to the skin, the gastrointestinal tract, the kidneys, and the heart. There may be associated symptoms of arthritis, and involvement of almost all organs has been noted. There is an associated fever in most instances, an increase in the number of leukocytes in the blood, and evidence of inflammation. No recognized specific mode of therapy is available.

Arteritis. Arteritis is an inflammation in localized segments of arteries. One particularly notable type is cranial arteritis (temporal arteritis), a disease of variable duration and unknown cause that is accompanied by fever and involves the temporal and occasionally other arteries of the skull. In general, older persons are affected. Excision of the involved artery may be carried out, but the general symptoms may remain.

Ergotism. Ergotism results from the excessive ingestion of ergot (a fungus that grows on rye and other cereals) and its derivatives. There is evidence of lack of blood flow and eventual gangrene in the small peripheral arteries, particularly in the legs, the nose, and the ears. Treatment includes use of measures to improve the circulation.

Arterial thrombosis. Arterial thrombosis, the formation of blood clots in arteries, occurs commonly in diseased vessels.

Frostbite. Frostbite may occur after exposure to subfreezing temperature momentarily or to less severe temperature for a longer period. It occurs more readily if blood vessels are diseased. Several degrees of frostbite produce thrombosis of the arteries and arterioles and also may involve veins. Symptoms may vary from a mild stage of reddening to gangrene and eventual loss of the extremity.

Types of embolus

Arterial embolism. An embolus, a foreign or abnormal particle circulating in the blood, may block a vessel too small to permit further passage. The sources of emboli include blood clots from the chambers of the diseased or abnormally functioning heart. Mural thrombosis on the infarcted ventricular wall or clots in the atrium in atrial fibrillation are common sources. Fat emboli may occur after fracture of bones and discharge of fatty marrow. Air emboli may be suspected after major injury, especially when large veins are opened during accidents or during vascular surgery of the neck or chest cavity. Bacterial emboli occur in bacterial endocarditis and occasionally in other infections. Cancers may produce minute emboli of tumour cells. Fungus growth or foreign materials, such as fragments of bullets, may become emboli. These emboli may cause transient local symptoms from diminished blood flow and may result in death of tissue. Treatment may include anticoagulant therapy and surgical removal of the clot.

Nonocclusive disease. *Arteriovenous fistula.* A penetrating injury such as that caused by a bullet or a sharp instrument may result in an opening between an artery and its immediately adjacent vein (an arteriovenous fistula). Large amounts of blood may be shunted from the artery to the vein. Arteriovenous fistulas are particularly common in wartime as a result of shell fragments and other types of injury involving the arms and legs. They may also occur as a complication of surgery. Others are congenital in origin.

The physician may hear a loud murmur caused by the turbulent flow of blood from the artery to the vein. Enlargement of the heart and all of the manifestations of congestive heart failure may occur if the amount of blood shunted is large. In the area around the site of the arteriovenous fistula, the blood vessels become dilated and bacterial infection of the artery lining may develop. A cure can usually be achieved by surgery, though in some situations the remaining arterial flow may be impaired.

A special kind of arteriovenous fistula occurs from the pulmonary artery to the pulmonary vein. Here the situation is complicated by the fact that unoxygenated venous blood is being shunted into a vessel normally containing oxygenated blood. Cyanosis results and produces a stimulation for formation of red blood cells, leading to a form of secondary polycythemia, abnormally high red-blood-cell level. Arteriovenous fistulas are treated by surgery.

Physical injuries. Physical injuries to arteries may lead to damage of the vascular wall, with consequent formation of blood clots and blockage. On other occasions, a form of inflammation may develop that may lead to rupture and may be the source of emboli in the peripheral arteries. Sudden disastrous external stress such as in severe automobile accidents, airplane crashes, and underwater explosions may cause death through rupture of the major arteries, such as the aorta, rupture of the heart valves, or rupture of the heart itself.

Radiation injuries. X ray, radium, and other radioactive substances in large dosages have marked effects on the vascular system. Initial reactions are inflammatory, and secondary changes caused by scarring and retractions may occur, which in turn lead to vascular occlusion (obstruction). The effects may be progressive for a period of years and are, at times, complicated by the development of cancer.

Raynaud's phenomenon and Raynaud's disease

Functional disease. *Vasoconstriction.* Raynaud's phenomenon is said to occur when the extremities, including occasionally even the ears, nose, or cheeks, become pale, cyanotic, and numb under the influence of cold or emotion. Pain is also present at times. On cessation of the stimulus redness develops and there is a tingling or burning sensation lasting some minutes. This sequence of events is apparently caused by the excessive constriction of the small arteries and arterioles of the fingers upon stimuli that ordinarily cause only a minor degree of vasoconstriction (constriction of blood vessels). Raynaud's disease, which is initially manifested by this phenomenon, is a disease in which there is spasmodic contraction of the blood vessels, usually beginning in early adulthood and affecting women about three times as often as men. The limb involvement is usually symmetrical (on both sides) and may lead to gangrene. Attacks may subside after return to a warm environment or release from tension.

The symptoms associated with Raynaud's disease may occur in people without other evidence of organic disease, especially in cold and moist climates. It may result from the operation of pneumatic hammers or may occur in individuals with various disorders such as a cervical rib, a supernumerary (extra) rib arising from a neck vertebra. It may appear as a complication of arteriosclerosis and thromboangiitis obliterans. Various substances, such as nicotine, arsenic, ergot, and lead, have occasionally been blamed. Therapy includes treatment of the primary condition and avoidance of the precipitating cause.

Acrocyanosis is a similar condition, characterized by episodes of coldness and cyanosis of the hands and feet. It is often associated with profuse sweating and, at times, with local edema. It is a form of local sensitivity to cold and is frequently seen in mentally or emotionally disturbed people or in those with neurocirculatory asthenia (a symptom-complex in which there is breathlessness, giddiness, and a sense of fatigue, pain in the chest over the heart, and palpitation, a fast and forcible heartbeat of which the affected person is conscious). Reassurance and avoidance of cold help to eliminate attacks.

Cause and relief of erythermalgia

Vasodilation. Erythermalgia (erythromelalgia) is an uncommon condition in which the extremities, especially the palms of the hands and the soles of the feet, are red, hot, painful, and often somewhat swollen. Dilation of the blood vessels (vasodilation) is the underlying factor. The condition is relieved by elevation of the extremity and

cooling. Usually it occurs in middle and later life and is chronic in the primary form; it may occur as a secondary manifestation of underlying vascular disease. It may also occur as a manifestation of an abnormally high red-blood-cell level and, occasionally, as the result of injury or a variety of other disorders.

DISEASES OF THE VEINS

Organic disease. In thrombophlebitis there is thrombosis (clot formation) in the veins and a variable amount of inflammatory reaction in the vessel wall. In some instances, the inflammatory reaction is predominant and thrombosis is secondary. In other instances, thrombosis appears before reaction in the vein wall. Embolization—breaking loose of a blood clot—is most likely to occur during this period, though it may occur at any stage of the disease. A form of the disease in which little or no inflammatory reaction or pain develops is called phlebothrombosis.

Thrombophlebitis most frequently involves the veins of the legs. It may occur without apparent cause and tends to recur. At times, it occurs as a result of local injury, either from a penetrating wound or from an external blow without a break in the skin. It may occur as a result of severe muscular effort or strain and in the course of infectious diseases, thromboangiitis obliterans, and a wide range of underlying diseases. Thrombophlebitis may develop in various parts of the body if there is cancer, especially cancer of the pancreas. The presence of varicose veins in the legs causes a tendency to the development of thrombophlebitis. Treatment includes bed rest and anticoagulant therapy.

Pulmonary embolism may occur in bedridden persons as a result of a clot from a thrombophlebitic lesion, or it may occur in an apparently healthy individual. If the embolus is small, it may not have any effect on the systemic circulation. With larger pulmonary emboli, there may be massive bleeding from the lungs and the development of a large area of pulmonary infarction, resulting in sudden death. Getting up and walking soon after an operation or after congestive heart failure is the best method for avoiding pulmonary embolism. Anticoagulant therapy is useful both as prevention and as therapy after the condition has developed. Surgical removal of a massive pulmonary clot has, on rare occasions, been spectacularly successful.

Varicose veins

Varicose veins are permanently tortuous (twisted) and enlarged. The medium and large veins, especially in the legs, are most likely to be affected. The condition may occur without obvious cause or as a result of postural changes, occupation, congenital anomaly, or localized causes of increased venous pressure. The veins may be near the surface and easily seen or they may be hidden and unrecognized. Without complication, they rarely cause symptoms, but they may become the site of thrombophlebitis with inflammatory changes and the production of emboli in the peripheral circulation. The veins may rupture on occasion, with bleeding into the surrounding tissues. Varicose veins may occur around the rectum and anus, producing hemorrhoids. If they occur within the scrotal sac in the region of the testes, they are called varicocele. In all forms of varicose veins, the walls of the veins become hardened, and a certain amount of inflammation develops through the years. Dilated veins in the legs may be supported by appropriate elastic-type stockings or bandages, or they may be treated by surgery.

Functional disease. Direct mechanical injury or an infection or other disease process in the neighbouring tissues may produce spasms in the veins (venospasms). Local venospasm is usually of relatively minor significance because of the adequacy of alternate pathways for the blood. If venospasm is widespread, however, involving an entire extremity, or the veins in the lungs, it may impair blood flow and therefore be of greater significance.

DISEASES OF THE CAPILLARIES

The capillaries are the smallest blood vessels. Through their thin walls oxygen and nutrients pass to the tissue cells, in exchange for carbon dioxide and other products of cellular activity. Despite the small size and thin walls of the capillaries, the blood pressures may be quite high as, for instance, in the legs of a person in a motionless, upright position. In certain disease states, there is increased fragility of the capillary wall, with resultant hemorrhages into the tissues. These hemorrhages are referred to as petechiae when small or, if large, may become a large area of discolouration of the skin. Vitamin C deficiency and a variety of blood disorders may be associated with increased capillary fragility. Small petechial hemorrhages occur in bacterial endocarditis and certain other infectious processes. In some instances, petechiae are caused by minute emboli; in others, they appear to be directly related to capillary fragility itself. Treatment is of the underlying disorder.

Capillary fragility

The capillaries are freely permeable to water and small molecules but ordinarily are not highly permeable to proteins and other materials. In some pathological situations, such as in certain allergic states (*e.g.,* hives) or because of local injury as in burns, there may be local areas of permeability, with escape of fluid high in protein into the surrounding tissues. If the disease affects the entire body, a significant amount of plasma (the blood minus its cells) leaks into the nonvascular spaces, with resultant loss in blood volume. Again, treatment is of the underlying disorder.

HEMODYNAMIC DISORDERS

Hypertension. Hypertensive heart disease has been discussed above.

Hypotension. Moderate hypotension (low blood pressure) may occur in persons who are weak and enfeebled but more often does not represent a diseased state. Indeed, life insurance figures demonstrate that the life expectancy of people with such a condition is greater than average. Hypotension of a severe degree may develop in heart failure, after hemorrhage, in overwhelming infections, and in a variety of circumstances that lead to the development of the clinical picture of shock. In shock, the circulation is inadequate, blood pressure is low, heart rate is rapid, and irreversible tissue damage from insufficient blood supply may occur if the condition is not terminated (see below *Physiological shock*). Transient hypotension may occur as a normal reaction in certain forms of syncope but is not necessarily associated with organic disease.

Syncope. Syncope is the sudden loss of consciousness associated with a transient disorganization of circulatory function, as differentiated from other brief losses of consciousness associated with abnormal central nervous system activities, as in certain forms of epilepsy.

Fainting

The most common kind of syncope is ordinary fainting. Some individuals are more susceptible than others. Blood loss, exhaustion, the presence of other illness, and psychological factors may contribute to a tendency to faint. An affected person is usually in the upright position, becomes weak, pale, and sweaty, and may have nausea. The heart rate at this time is usually relatively rapid, but with the abrupt onset of syncope the heart rate falls often to below the normal level and the person collapses as if dead. There is usually a rapid recovery without complications.

Syncope may be related to a transient cessation of circulatory activity due to heart block. Other forms of syncope occur as a result of lowered blood pressure upon assumption of an upright position, a condition often called orthostatic hypotension. In some individuals, disease of the autonomic nervous system prevents appropriate postural adjustments for the upright stance. The disorder may be caused by vascular or central nervous system involvement of the autonomic system. In other instances, postural hypotension may occur as a result of inadequate blood volume, of taking various drugs that affect the nervous control of the circulation, and from a wide variety of other causes. Transient hypotension also may result from hypersensitivity of the carotid sinus. (J.V.W./M.F.O.)

PHYSIOLOGICAL SHOCK

Physiological shock may be defined as acute progressive circulatory failure in which the tissues receive an inadequate supply of blood and its components (such as nutrients and oxygen) and an inadequate removal of wastes. The result is cell damage and, eventually, cell death. This

definition is derived from the one constant feature of physiological shock, the failure of adequate blood flow through the capillaries, the smallest of the blood vessels. Shock may be so severe as to impair organ function or create a state of blood flow deficiency that grows progressively more dangerous.

All, or some, of the following features may be present: a raised pulse rate, each pulse being diminished in strength, or "thready"; diminished arterial blood pressure; a cold, sweaty skin; rapid, deep respirations (breathing called air hunger in this context); mental confusion; dilated pupils; a dry mouth; and diminished flow of urine.

Many classifications of various types of shock have been developed, the most popular being one that relates the state to its cause; *e.g.,* hemorrhage (bleeding) or sepsis (invasion by pus-forming organisms). This classification has the advantage of possessing diagnostic and therapeutic implications, but unfortunately the cause of shock is often uncertain. Alternatively, the state may be called hypovolemic if it is associated with a reduction in blood volume or normovolemic if no blood-volume diminution has occurred. Shock can also be subdivided into "warm hypotension," if the sufferer has lowered blood pressure and warm dry skin, and "cold hypotension," if the skin is cold.

Shock due to inadequate blood volume. Hemorrhage is the most common cause of shock. In the "average man" (weighing 70 kilograms, or about 154 pounds) the blood volume is about five litres (about 5.3 quarts), and the loss of any part of this will initiate certain cardiovascular reflexes. Hemorrhage results in a diminished return of venous blood to the heart, the output of which therefore falls, causing a lowering of the arterial blood pressure. When this occurs pressure receptors (baroreceptors) in the aorta and carotid arteries will initiate remedial reflexes either through the autonomic (nonvoluntary) nervous system by direct neural transmission or by epinephrine (adrenaline) secretion into the blood from the adrenal gland.

Baroreceptors

The reflexes consist of an increase in the rate and power of the heartbeat, increasing its output; a constriction of arterioles leading to nonessential capillary beds (notably the skin and some viscera); and a constriction of the veins, diminishing the large proportion of the blood volume normally contained therein. By these means arterial blood pressure will tend to be maintained, thus preserving blood flow to the vital areas such as the brain and the myocardium. After continued acute blood loss of 20–30 percent of the blood volume, the compensatory mechanism will begin to fail, the blood pressure will begin to fall, and shock will ensue.

Increased sympathetic (autonomic) nervous activity thus accounts for the fast pulse rate, pallor, and coldness of the skin in shock and, in addition, is the cause of increased sweating and dilation of the pupils of the eyes. Air hunger and mental confusion are caused by the inadequate carriage of oxygen, and decreased urine flow stems from a decrease in the renal (kidney) blood flow, which, if severe, can lead to kidney failure. If acute blood loss continues beyond about 50 percent, the inadequacy of flow through vital circulations will lead to death. Loss of whole blood is not necessary for the blood volume to be low, for plasma loss through burnt areas of the skin, dehydration following inadequate intake of fluid, or exceptional fluid loss can lead to contraction of the blood volume to levels capable of causing shock.

When it is possible to anticipate blood loss, and to measure it accurately—*e.g.,* during an operation—losses may be immediately replaced before significant volume depletion can occur. More often, however, hemorrhage is unexpected; it may not be possible to measure the amount of blood lost. If shock occurs in an otherwise healthy person it generally is replaced by transfusion into a vein. But since a preliminary matching between recipient serum and donor cells must be carried out, and cannot be done in less than 20 minutes, other fluid is usually given intravenously during the delay. This fluid, such as plasma or a solution of the carbohydrate dextran, must contain molecules large enough that they do not diffuse through the vessel walls. Since the main loss from burns is plasma and electrolytes, these require replacement in proportion to the area of the burn and the size of the patient.

Shock due to inadequate cardiac output. Sudden interference with the blood supply to the heart muscle, as by a thrombosis in a coronary artery, causes damage to the muscle with resultant diminution in its contractile force. The output of the heart falls; if the decline is severe, a fall in blood pressure stimulates the baroreceptors and, in the way just described, cardiogenic shock results. This occurs uncommonly after myocardial infarction. But low heart output alone may not account for the shock, for in chronic heart failure the cardiac output may be low without such a response in the peripheral circulation.

Cardiogenic shock

Shock due to increased circulatory capacity. If widespread dilation of the veins or of the capillary beds occurs, the blood volume is no longer sufficient to fill the larger space and shock ensues.

Bacteremic shock. Infection anywhere in the body may spread to the circulation, and the presence of organisms in the bloodstream—bacteremia—may lead to shock. Bacteria are conveniently divided into "gram-positive" and "gram-negative" groups according to their reaction to a special staining method called Gram's stain.

Gram-negative bacteremia is the more common and more lethal type of bacteremic shock. It is frequently caused by *Escherichia coli, Proteus, Pseudomonas,* or *Klebsiella* organisms; the first of these normally inhabits the intestine. The clinical picture of gram-negative bacteremia is much like that of hemorrhage, although no blood has been lost. This type of shock typically causes a rapid, thready pulse; a cold, sweaty skin; and low blood pressure. A fever may occur, in addition to the local signs of the associated infection. The cause of the type of reaction is uncertain. The response to bacteremia from gram-positive organisms such as *Staphylococcus* and *Streptococcus* is different. Widespread dilation of the blood vessels results in a warm, dry skin and a full volume pulse in spite of lowered blood pressure.

In both types of bacteremia the condition may be exacerbated by contraction in blood volume. This follows fluid loss, *e.g.,* that lost in the peritoneal cavity in peritonitis—inflammation of the peritoneum, the membrane that lines the abdominal cavity; in the tissues in streptococcal infection; or through the intestine in enteritis (inflammation of the intestine).

Exceeded in frequency only by cardiogenic and hemorrhagic shock, bacteremic shock is most often caused by gram-negative organisms. There are three aspects of treatment: collections of pus are drained as soon as possible; the circulatory volume is increased to compensate for enlargement of the vascular bed; and appropriate antibiotics are administered.

Treatment

Anaphylactic shock. Anaphylactic shock is discussed in detail in the article IMMUNITY. An anaphylactic reaction is the direct result of the entrance of a specific foreign material into the bloodstream of a person whose body has become sensitized against it as a result of previous exposure and subsequent formation of antibodies. During an anaphylactic reaction, lung bronchi constrict intensely, narrowing the airways and interfering seriously with respiration; blood pressure may fall precipitously because of the release of substances (serotonin, histamine, and bradykinin) that cause dilation of the arterioles and venules and an increase in the capillary-wall permeability. Thus the circulatory capacity is increased, and fluid is lost into the tissues.

The essence of treatment of anaphylactic shock is the injection of epinephrine, a powerful stimulatory drug also found naturally in the body, whose effects include an increase in the heart rate and constriction of the blood vessels, followed by an antihistamine, to counteract the reaction to the foreign substance, and a bronchodilator, to ease breathing.

Psychogenic shock. Psychogenic shock causes fainting, probably by initiating dilation of the blood vessels that perfuse the muscles. In this type of shock, blood pressure falls, the skin becomes cold and sweaty, and the pulse rate increases. A decrease in the amount of blood that is supplied to the brain leads to light-headedness and loss of

consciousness. A person who is suffering from psychogenic shock should be placed flat or even with the head slightly lower than the rest of the body in order to restore a good flow of blood to the brain and to bring about recovery from the fainting.

Drugs and shock. Most anesthetic drugs—nitrous oxide is a notable exception—have a profound effect on the circulation. They are able to decrease the contractility of the heart muscle as well as increase the circulatory capacity by dilating the blood vessels. In addition, the normal postural circulatory reflexes are lost, so that pooling of blood in the legs is liable to occur if the affected person is tilted to a head-up position. This is of particular importance after surgery; if a person is made to sit up too soon, it can lead to low blood pressure and an insufficient flow of blood to the brain. Overdosage of certain drugs, notably barbiturates, narcotics, and tranquilizers, blocks normal circulatory reflexes and causes dilation of the blood vessels, leading to a fall in blood pressure that often is accompanied by a slow, full-volume pulse.

A blood pressure that is dangerously low may be raised to safer levels by affecting the activity of the offending drug in one of many different ways. A therapeutic approach might entail, for instance, decreasing the dosage of the drug (such as an anesthetic agent), speeding up its elimination from the body, or administering a substance that is able to constrict the blood vessels. The choice of approach depends on the individual circumstance.

Neurogenic shock. The maintenance of the tone of the blood vessels by the autonomic nervous system may be affected by severance of one of these nerves or by its interruption of the flow of nervous impulses. Thus, spinal anesthesia—injection of an anesthetic into the space surrounding the spinal cord—or severance of the spinal cord results in a fall in blood pressure because of dilation of the blood vessels in the lower portion of the body and a resultant diminution of venous return to the heart.

Neurogenic shock does not usually require specific therapy; indeed, spinal anesthetics may be given with a view to producing a low blood pressure so as to diminish bleeding during an operation. If blood pressure becomes critically low, the legs are sometimes elevated and a vasoconstrictor administered.

Endocrine causes of shock. The endocrines play a vital role in the regulation of normal metabolic processes through the actions of their hormones. It is not surprising therefore that a malfunction in an endocrine gland or in its hormones has an effect on circulation. Inadequate secretion by the adrenal cortex, the outer substance of the adrenal gland, leads to shock both by the diminution of myocardial efficiency and by a decrease in the blood volume. Functional disorders of the pituitary, the adrenal medulla (the inner substance of the adrenal gland), the thyroid, and the parathyroids can all lead to circulatory upset and shock.

Definitions

Refractory and irreversible shock. The terms refractory shock and irreversible shock are widely used by physicians and other medical workers to refer to types of shock that present particularly difficult problems. The term refractory shock is applied when in spite of apparently adequate therapy the shock state continues. Commonly the treatment proves later to have been inadequate, in which case the shock was not true refractory shock. This often occurs following a major injury in which there is internal bleeding, leading to underestimation of true blood loss and therefore to inadequate transfusion. In certain cases, however, even if the therapy actually is appropriate, the shock state persists; if patients in such cases respond to further special treatment, then this is true physiological refractory shock.

In severe or prolonged shock states the myocardial blood supply is diminished sufficiently to damage the heart's pumping action temporarily or permanently. Also, noxious products of inadequately perfused tissues may circulate and affect the heart muscle.

While the flow of blood through major vessels is under the control of the nerves, circulation through the capillary beds is of a more primitive type and is under the influence of local metabolic products. In shock, arteriolar constriction causes inadequate flow through the tissues and local waste products increase. These cause dilation of the capillary sphincters and opening of the whole capillary bed, which thus contains an increased proportion of the blood volume. The capillaries become further engorged with slowly flowing blood, and fluid leaks through the vessel walls into the tissues. Thus the body is further deprived of circulating blood volume.

Possibility of clotting in capillaries

Widespread clotting of the blood can occur during capillary stagnation. This leads to severe damage to the cells unsupplied by flowing blood. Later, when the clot is dissolved under the influence of enzymes that dissolve the fibrin of the clots, the flow through these areas carries toxic metabolic products to vital organs such as the heart, kidneys, or liver, and the ensuing damage leads to irreversibility of shock.

Identification of the causes of shock. Several causes of shock may be present in any given instance. For example, in peritonitis—inflammation of the lining membrane of the abdominal cavity—bacteria enter the bloodstream as a result of the infection, and fluid loss into the peritoneal cavity leads to a low blood volume. In pancreatitis, inflammation of the pancreas, the cause of shock may be threefold: bleeding and escape of fluid into the tissues may lead to diminished blood volume; there may be increased release of the vasodilator bradykinin, leading to increased circulatory capacity; and bacteremia, the presence of bacteria in the bloodstream, may exist. In severe infection with *Streptococcus* organisms, there may be bacteremia, a low blood volume from loss of fluids into the tissues, and toxic damage to the heart muscle.

Hemorrhage may present no difficulties in recognition, since losses of blood from the intestine or from wounds and fractures usually have particular features. The bleeding, however, may not be evident if it occurs in the chest or abdomen after trauma or if the blood fails to drain from deep-seated operative wounds. When bacteremia occurs there is often an obvious source of infection, such as peritonitis, pneumonia, or urinary tract infection, but such loci of infection may be small or deep-seated, so that final proof of cause has to be determined from culture of the blood.

Cardiogenic shock usually occurs only along with typical features of coronary thrombosis—severe central chest pain perhaps radiating to the arm or neck and showing typical changes on an electrocardiogram (ECG). But myocardial infarction, the death of a section of heart muscle, can occur without causing any signs; it may happen while a person is under anesthesia, for example, and it does not always produce typical changes in the ECG at first. Furthermore, low blood pressure from any cause can result in ECG changes, further obscuring the cause of shock.

Prognosis. During the course of treatment, some indication of the outlook may be had from measurement of the lactic acid in the blood. The higher its level, the greater is the chance of irreversibility. The outlook may also depend on the cause of shock and the speed and vigour with which it is treated. At one end of the scale the mortality of immediately treated shock following hemorrhage is small, while at the other severe cardiogenic shock carries a mortality rate of about 80 percent. In septic shock the mortality is about 50 percent. (W.G.Pr./Ed.)

Circus

In its modern sense the word circus refers to an entertainment composed primarily of trained animal acts and exhibitions of human skill and daring. The word has the same root as *circle* and *circumference* and therefore also recalls the distinctive environment in which such entertainment is presented—the ring, a circular performance area usually bounded by a short fence (or "curb") and surrounded by tiers of seats for spectators, which may itself be enclosed in a circular building or tent. But variations exist, and any attempt at a strict, all-inclusive definition would reduce the term's application to a particular nationality, generation, or proprietorship. Some circuses dispense with trained animals, for example; others, particularly in the United States, exhibit simultaneously in three or more rings, with the building or tent then taking on a rectangular or elliptical shape. At various times circuses have offered supplementary attractions such as street parades, menageries, sideshows or "museum" departments, and pantomimes and theatrical presentations. A number of circuses, especially in Europe, have been stationary, occupying permanent, often elegant buildings in the larger cities. Others have traveled extensively—originally by horse and wagon, then by railroad, boat, motor vehicle, or even airplane—exhibiting in tents or, occasionally, theatres and, more recently, in huge enclosed sports arenas. A few organizations, such as Ringling Bros. and Barnum & Bailey, can point to a history extending back a century or more; other circuses, such as those sponsored by fraternal organizations (*e.g.*, the Shriners), may exist for less than a single season. Some shows have traditionally emphasized spectacular elements such as gorgeous costumes, floats and pageant wagons, numbers set on water or ice, or perhaps a theme running through part or all of the program. Others have been built around the talents of outstanding individual artists such as the 19th-century American clown Dan Rice or the sensational German animal trainer Gunther Gebel-Williams. Through all the above, however, there runs a common thread: the ring, by which spectators readily recognize the entertainment known as "circus."

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 622.

This article is divided into the following sections:

ORIGINS OF THE CIRCUS

Early entertainers

Contrary to popular opinion, the circus is of comparatively recent origin, having little in common with ancient Roman circuses and amphitheatres. The former were in fact racecourses, whereas the great oval amphitheatres were most often devoted to gladiatorial combats, the slaughter of animals, mock naval battles, and spectacular pantomimes. Certainly many numbers associated with the circus were known to ancient peoples. Acrobatics and juggling are probably as old as mankind itself; the Greeks saw ropedancers perform; the Romans made a specialty of training animals, including elephants, which were also supposedly taught to walk ropes; and clowns are found in nearly every period and civilization, both as characters in farces and as individual performers. Until the mid-18th century, however, there were no attempts to organize such acts into a distinct entertainment, although in the meantime they had continued to be exhibited by individuals and small troupes of performers who wandered through Europe, Asia, and Africa. They appeared wherever groups of people gathered: in nobles' halls, at community celebrations, and at marketplaces. King Alfred the Great of England (reigned 871–899) was entertained by a wild beast show; William the Conqueror (king of England 1066–87) brought performing troupes of ropedancers, tumblers, and contortionists from France to England. Itinerant players trained bears, monkeys, horses, dogs, and other animals and brought them to fairs. Fairs played an important role in developing trade throughout Europe from the 7th century onward. By the late medieval period, however, as more regular channels of marketing were standardized, they tended to become less a place for trading than for entertainment, featuring many of the performers, animals, and other characteristics later associated with the circus.

The modern circus came into being in England in 1768 when Philip Astley (1742–1814), a former sergeant major turned trick rider, found that if he galloped in a circle while standing on his horse's back, centrifugal force helped him to keep his balance. In doing so he traced the first ring. Astley soon engaged a clown ("Mr. Merryman"), musicians, and other performers for his establishment, roofed over his ring, and added a stage for dramatic performances. Astley himself always referred to his building, which was located on the Lambeth side of London's Westminster Bridge, as an "amphitheatre" or "riding school." The term "circus" was first employed in 1782 when a rival horseman and former employee named Charles Hughes opened the Royal Circus a few hundred yards south of Astley's Amphitheatre.

Circumstances were favourable for the development of the circus. During the second half of the 18th century the fairs were going into decline, and some of their main attractions were banned. Many showmen, looking for a new outlet, found it in the circus, as did ropedancers, acrobats, jugglers, and others whose performances were based on dexterity, agility, and strength and who discovered that their performances were better appreciated in the ring.

Spread of the circus through Europe

In 1772 Astley went to France to present his "daring feats of horsemanship" before the king and the French court, and he found that there, too, many showmen were ready to forsake the fairgrounds. Ten years later he returned to Paris and opened an amphitheatre. When hostilities between Britain and France developed after the outbreak of the French Revolution, he leased it to Antonio Franconi (1737–1836), a member of a noble Venetian family, who had been forced into exile after a fatal duel. He became first a showman and later a trick rider, but it was as a director that he excelled. Franconi joined forces with Astley and, in Astley's absence, continued on his own. His sons, Laurent and Henri, together with their wives

and children, continued in his footsteps, and the Franconi family is generally credited with being the founders of the French circus. They are reputed to have standardized the diameter of the ring at 13 metres (approximately 42 feet), a size that is still recognized in most circuses.

In 1782 Astley traveled as far as Belgrade, visiting Brussels and Vienna on the way, and during his life he built at least 19 permanent circuses. It was Hughes, however, who introduced the circus to Russia. He added a company of trick riders to the stud of horses he had been commissioned to deliver to Catherine the Great in 1793, and he was rewarded with a private circus in the royal palace in St. Petersburg. The Russian circus was further developed by a Frenchman, Jacques Tourniaire (1772–1829).

In 1793 John Bill Ricketts, a rider who had previously performed in Britain, opened circuses in Philadelphia and New York City, the first seen in the New World. At the same time Benito Guerre was presenting his feats of horsemanship in Spain, and a cut on a contemporary handbill shows a rider leaping through a paper hoop—a scene that still epitomizes this form of entertainment. By the turn of the century the circus had spread throughout Europe and was firmly established in America. Performances were still given mostly in permanent or semipermanent buildings of flimsy construction. The greatest hazard was fire, from which Astley and Ricketts suffered particularly: Astley's Amphitheatre burned down three times in the first 62 years of its history, and Ricketts lost his circuses in both New York City and Philadelphia as a result of fires.

From the time of its origin in England the circus was often coupled with the theatre. At Astley's, the Royal Circus, and elsewhere a proscenium arch and large scenic stage were set behind the ring. Equestrian drama, with plots based on famous battles and sieges and with the horses and other artists participating at full gallop, became all the rage. In France this genre of entertainment was eventually exiled to regular theatres, but in England it continued to flourish in permanent and tenting circuses throughout the 19th century. Shakespeare's *Richard III* and *Macbeth,* and even Verdi's opera *Il trovatore,* were performed on horseback at Astley's during this period. Astley's, however, never became as fashionable as the permanent circuses on the Continent. The most exclusive club in Paris kept its own private box at the Cirque d'Été, and in St. Petersburg the stables were regularly scented for the benefit of aristocratic visitors.

Equestrian drama

Circus families

Circus families can became prominent during the 19th century. From one generation to another, members of a family would be trained from earliest childhood in the skills and discipline necessary to achieve perfection either in one specialty or in a group of related specialties. For example, the Cristiani family of Italy was known chiefly for its expert riders, but some members excelled in the skills of tumbling, ballet, and acrobatics. Circus families often intermarried. The Cooke family, which traveled from Scotland to New York City in the early 1800s, was an equestrian group that intermarried with the Coles and the Ortons, both well-known American circus families. As a circus family expanded, branches were established in numerous areas and members often went from one branch to another. The Cristiani family established branches elsewhere in Europe and the United States. Toward the end of the 19th century the Russian circus was dominated by an Italian circus family, the Cinisellis, which, like many others, made its name outside its own country.

At the beginning of the 20th century the circus was still spreading to many other countries. The British circus family of Harmston settled in East Asia, and for years their only rival was the Russian circus, Isako. The Boswells left England for South Africa, where they met competition from the German Pagel. Frank Brown, whose father had been a clown at Astley's, toured South America for many seasons. In Australia the circus prospered under the Wirths. The Lobes, from Budapest, made Persia their tenting ground, and the Sidolis settled in Romania.

CIRCUS ATTRACTIONS

Equestrian acts. From its origin under Astley, the circus has retained performing horses and riders as a fundamental feature. Most great riders have been champions of the art of bareback riding, performing acrobatic and gymnastic feats on the bare backs of loping horses. James Robinson, a mid-19th-century American, was one such rider. He was billed as "the One Great and Only Hero and Bareback Horseman and Gold Champion-Belted Emperor of All Equestrians." Horses that perform free of rider, reins, or harness, directed solely by visual or oral command, are called liberty horses. The Barnum & Bailey Circus, the most famous name in the American circus, in 1897 presented the largest troupe of liberty horses, 70 performing simultaneously in one ring. The traditional finale of the larger tent shows was the Great Roman Hippodrome Races, composed of novelty races, steeplechase, and the ancient arts of chariot racing and Roman standing riding.

Another type of riding, extremely popular in the 19th century before the purely acrobatic style supplanted it, was scenic riding, in which the equestrian, appropriately costumed, acted out a pantomime on horseback. The greatest exponent of this artistic mode of riding was the Englishman Andrew Ducrow (1793–1842), who also managed Astley's during the last two decades of his life. One of his creations, "The Courier of St. Petersburg," is still seen in the circus. In this act a rider straddles two cantering horses while other horses, bearing the flags of those countries that a courier would traverse on his journey to Russia, pass between his legs. Besides other solo acts, which were copied by equestrians throughout the world, Ducrow invented several duets and ensemble numbers. In "The Tyrolean Shepherd and Swiss Milkmaid," for example, he was joined by his wife, Louisa Woolford, and, while standing on the backs of their circling horses, the two performed the pursuit and wooing of the fair peasant, complete with a lovers' quarrel and reconciliation scene, followed by an exquisite pas de deux.

Keystone

D. Kossmeyer, in Bertram Mills Circus, London, performing an equestrian act reminiscent of feats originated by Andrew Ducrow.

Equestrian acts of the 20th century can be divided into three main groups: voltige, in which a rider vaults onto and off a horse's back; trick riding, in which the standing rider performs somersaults and pirouettes or forms human pyramids with other riders on one or more horses; and high school, a spectacular form of dressage in which a horse executes complex maneuvers in response to imperceptible commands communicated through slight shiftings in the rider's weight, pressure exerted by the knees and legs, or the handling of the reins. The Schumann fam-

Voltige, trick riding, and high school

ily, for many years directors of the permanent circus in Copenhagen, excelled in high school and also exhibited many fine liberty-horse acts.

Wild animal acts. The introduction of wild animals to the circus dates from about 1831, when the French trainer Henri Martin (1793–1882) performed with his lions, boa constrictors, elephant, and other animals at the Cirque Olympique in Paris. He was soon followed by the American trainer Isaac A. Van Amburgh (1801–65), reputedly the first man to stick his head into a lion's mouth, who in 1838 took his act to England and so fascinated the young Queen Victoria that she commissioned the artist Edwin Landseer to paint a portrait of the brawny American with his "big cats." In addition to exhibiting at circuses, both Martin and Van Amburgh frequently appeared on the boards of regular theatres, where they and their animals were featured in melodramas with such titles as *The Lions of Mysore* and *The Brute Tamer of Pompeii*. Other dramas performed in theatres and circuses about this time featured elephants and bears in starring roles.

Until the late 20th century there was a marked difference between European and American styles of presenting wild animal acts. Van Amburgh customarily beat his animals into submission, and the belief that the trainer must demonstrate physical superiority over his "pupils" was held by many of his successors. The master of this style in the 20th century was the American Clyde Beatty (1903–65), who subjugated as many as 40 "black-maned African lions and Royal Bengal tigers" at one time.

By courtesy of Circus World Museum, Baraboo, Wis. and Ringling Bros. and Barnum & Bailey Circus

Clyde Beatty training lions, *c.* 1932.

In the European style of presentation, as developed by the Hagenbecks in Germany about the end of the 19th century and now followed by most American trainers as well, the trainer endeavours to prove his mastery and skill by presenting his jungle charges in the role of obedient, even playful, pets. The wild character of the animals, however, is revealed just often enough to remind the spectator that what he sees is indeed the result of skillful training.

The hallmark of circuses

Elephants are considered by many to be the very hallmark of the circus. Their awesome size makes their adaptability to humans a curious paradox. From single specimens exhibited at Astley's in the early 19th century, the number of performing elephants, especially in American three-ring circuses, has sometimes run as high as 50 or more. Despite their pleasant-looking appearance and ability to learn a surprising variety of feats, these seemingly docile beasts are among the most dangerous of circus animals.

Countless other species of wild animals have been trained to perform in the circus ring, including polar bears, giraffes, hippopotamuses, and rhinoceroses. The members of the Knie family of Switzerland are celebrated for their expertise in the handling of such exotic animals.

Acts of skill. In 1859 the invention of the flying trapeze by the French acrobat J. Léotard (1838–70), and Charles Blondin's crossings of Niagara Falls on a tightrope in the same year, rekindled the public interest in the work of the aerial gymnast and acrobat. Although the trapeze had never been seen before, ropedancing can be traced to ancient Greece. By the turn of the century, acrobats had had an extensive influence, although they never usurped the supreme position of the horse.

The Bubnovs, aerial gymnasts from the Moscow Circus.
Novosti Press Agency

The human performer offers not the mystery of the exotic circus animal but the realization that a fellow human being, of the same substance as the spectator, can achieve astonishing discipline and mastery. The circus audience identifies itself with the performer as he or she attempts a feat of daring or skill. Completion of such feats as a double somersault to a four-high human pyramid fills the crowd with satisfaction and relief. A misstep on the tightwire seems to elicit greater distress in the spectators than in the performer. And the circus performance is not on film or tape but live: there can be no retake to erase an error. With evidence of human weaknesses and failures so prevalent everywhere, the circus is unusual in showing people at their best in physical achievement and skilled coordination. This realization comes to mind, for example, at the sight of the Wallendas, a family of high-wire artists originally from Germany, balancing three-high on bicycles on the high wire. For Americans it may have come from seeing petite Lillian Leitzel, born in Bohemia of a German circus family, who could pivot a hundred times on her shoulder socket in a maneuver called the "plange"; she spun from a rope like a pinwheel. Again, its source may have been the skill of Australian-born Con Colleano, "the Toreador of the Tight Wire," whose dance on the wire to a Spanish cadence thrilled American audiences for decades; or perhaps it was the grace and perfect timing of the Mexican trapeze artist Tito Gaona, who—even blindfolded—flawlessly performed the triple somersault from bar to catcher.

National traditions

Traditionally, certain nationalities tend to dominate specific areas of circus performance. Just as bareback riding long remained an English specialty and wild animal training a specialty of Germans and Americans, acrobatics and tumbling remain the realm of eastern Europeans. Asians excel in juggling and balancing acts and Mexicans in the flying trapeze. Although there are frequent exceptions to these tendencies, especially in recent years, these and other traits are identifiable. Such traditions may be related to the existence of circus families, whose specialties are passed on for several generations. To many people, such a life would appear to be a nomadic existence, without either the comforts of a permanent residence or the security of

permanent employment. On the other hand, to experience circus life is to see apparent disadvantages become sources of strength. The appeal of a traveling life is strong to many, as is the bond that is built between show people in overcoming common hardships.

Function of clowns

Clowns. When the human capacity for amazement, thrill, and suspense approaches its limits, the circus unleashes its clowns to freshen the atmosphere, lighten the emotional load, and recondition the spectator's mind for the next turn. By tradition, there are several varieties of clowns, from the elegantly costumed whiteface clown, favoured in many European circuses, who appears rather severe and domineering; to the happy-go-lucky grotesque variety, whose exaggerated makeup and costumes are more outrageous and less predictable; to the woebegone, down-and-out "tramp" character, as popularized above all by the American Emmett Kelly. In 19th-century one-ring circuses it was usual for clowns to entertain audiences with songs and long monologues, in which they sometimes offered words of wisdom on politics and current events or quoted Shakespeare. More recently, especially in Russian circuses, a number of clowns have attempted to strike out in new directions, abandoning traditional costumes and makeup and developing more natural characters. The great Russian clown Oleg Popov became well known not only in the Soviet Union but also in Europe and America through his tours with the Moscow Circus. Wearing a minimum of makeup, he appeared in the ring with little to set him apart from the others except a slightly unconventional wardrobe. Like other great comedians of the world, his mere appearance brought anticipatory laughter from the audience. Popov impersonated a rube character who is forever trying to mimic the legitimate performers. Frequently he almost succeeded, but only after sufficient bungling to make his performance a comedy. Actually, in areas such as balancing on the slack wire and juggling, he demonstrated professional abilities.

Supporting attractions. *Band music.* Behind it all is the circus band, setting the pace and mood and cuing the acts. The composition of circus music has, over the years, become an art of its own. Playing such characteristic forms as the march, the gallop, the fox-trot, the tango, or various national airs, the circus band maintains the tempo of each event. It signals the change of emphasis among the simultaneous presentations as one event after another is highlighted, maintaining the seemingly perpetual flow of music.

The menagerie. Exotic animals such as camels and lions, brought to America by enterprising ship captains and sold to showmen, had been shown in the colonies in the 18th century. About 1815 Hackaliah Bailey, of Somers, N.Y., toured New England with his elephant, "Old Bet," whose success inspired Bailey's farmer-neighbours to set out with menageries of their own. In a very short time, there were noteworthy traveling collections of wild animals, such as the Zoological Institute of June, Titus & Angevine and Van Amburgh's Menagerie, which also set up permanent establishments in the larger cities. Similar developments occurred in England, leading to such famous traveling shows as Wombwell's Menagerie. Subsequently, circuses and menageries were combined. By the time American circuses achieved their massive character in the 1870s, the menagerie was a major feature, and it remained so through the 1940s. The circus menagerie was exhibited in a separate tent, and audiences passed through here before going into the main performance. The beautifully carved wagons that held the wild-animal cages lined the perimeter of the tent. The elephants were chained in position, and the "lead stock," including uncaged animals such as camels, llamas, bison, and zebras, were picketed together. The larger circuses had extensive collections, including rhinoceroses and giraffes in their own portable corrals.

The sideshow. In 1871, after he had already achieved success through his famous New York museum, P.T. Barnum entered into a partnership with William C. Coup and the former clown Dan Castello to found "P.T. Barnum's Museum, Menagerie, and Circus." It offered several attractions borrowed from his earlier museum, from which evolved another major feature of American circuses—the sideshow, or annex. Typically this included human "abnormalities," such as fat ladies, giants and midgets, "armless wonders," and four-legged girls; illusions and magicians; automatons and curious inventions; and various works of art, among them Hiram Powers' titillating nude statue "The Greek Slave." Housed in its own tent, the sideshow typically was fronted by giant banners or panels illustrating the marvels inside. A unique and vital element of the sideshow was the barker, whose foghorn voice and unceasing patter attracted the public to the show.

Unusual exhibits

COMMERCIAL AND TECHNICAL ASPECTS

From 1840 onward, circus combines and amalgamations became widespread in the United States, and partnerships were made and broken with bewildering frequency. In 1907, following the death of Barnum's final partner, James A. Bailey, the Ringling brothers, who had started out in the 1880s, bought Barnum & Bailey Circus and continued to run it as a separate show, finally combining it with their own circus in 1919 to form the concern that still flourishes as Ringling Bros. and Barnum & Bailey. In 1929 the Ringlings bought the American Circus Corporation, a syndicate comprising five circuses, with a view

to ensuring their supremacy in the field. Such attempts at monopolies were never the case in Europe, however, where families tended to split up rather than combine, so that more than one circus may bear the name Pinder, Fossett, Ginnett, or Sanger.

The mid-19th century was a period of great technical development in the United States. Spencer Q. Stokes invented the derricklike apparatus for training trick riders, which still goes by the name of the American Riding Machine. At one time his circus traveled by riverboat, though he did not give performances on a showboat as did "Dr." Gilbert Spaulding (1811–80). This former chemist from Albany, N.Y., is said to have invented quarter poles (which support the canvas roof of the big top between the central king poles and the side poles) and was also one of the first circus proprietors to experiment with railroad transport.

The circus train. Before 1872 most itinerating circuses moved from town to town by horse and wagon, a form of transport that necessarily limited their size and the distances they could cover in a given season. In the spring of that year, Barnum and his partners loaded their show onto 65 railroad cars, thereby giving birth to the age of the giant railroad circuses. Barnum's own "Greatest Show on Earth" eventually traveled on three separate trains, going distances of 100 miles or more in a single night; and in the 20th century Ringling Bros. and Barnum & Bailey once crisscrossed the country aboard four trains comprising 107 70-foot cars.

Railroads were more frequently used in the United States than in any other country. In Europe rail transport for circuses was never very popular, and, although a few attempts at traveling by rail were made, it was not until the second quarter of the 20th century that rail travel came into regular use by any European show. In Latin America and East Asia it was used, when available, after 1900. William C. Coup introduced the end loading of circus trains, in which the gaps between flatcars were bridged by iron plates and each wagon, fully loaded, was pushed down the length of the train to its assigned place. A model of logistic efficiency, circus methods led the way to the creation of the modern system of rail-truck freight handling.

The parade. The free circus street parade evolved in the United States as a triumphal entry into town by each overland circus caravan. By the 1840s it was recognizable as a parade with bandwagons and trappings. It was the English, however, who created the finest and most ornately carved circus parade wagons. In 1865 Seth Howes imported to the United States several English wagons, which prompted an upsurge of interest in circus parades. These processions, which wound their way through the town back to the circus field ("lot" in the United States, "tober" in Britain), were a great feature of British tenting circuses, particularly that of "Lord" George Sanger (1825–1911), who also owned Astley's Amphitheatre from 1871 until it was demolished in 1893. (Once Sanger even tacked his parade onto the end of a military escort accompanying Queen Victoria across London.)

In the United States the circus parade was the climax of a highly systematized publicity campaign to arouse interest in the circus during its brief appearance at any one place.

The first steps were taken by the general agent of the circus, who made arrangements for a city license, showgrounds, railroad routing, and other details. The impact of organized publicity hit the community when the first advance car arrived in town two or three weeks before show day. In larger shows as many as four advance advertising cars involving 60 to 80 men were used. A concentrated mass publicity campaign then unfolded. Billposters, lithographers, and banner men plastered the town and its environs with tens of thousands of square feet of "paper." The programmer recruited youngsters to scatter thousands of printed heralds, multi-paged couriers, handbills, and "rat sheets" (used to disparage other circuses when they happened to be in the same vicinity at the same time). Press agents turned the power of the press to the purposes of the circus. Other agents attended to such matters as water, food, fuel, feed, and preparations for showgrounds and railroad crossing.

Heralds, handbills, and "rat sheets"

On circus day itself the train arrived with its stockcars, perhaps with animals probing outside openings, and a long line of flatcars loaded with red baggage wagons, pole wagons, bandwagons, tableaus, chariots, the steam boiler wagon, and canvas-covered wild-animal cages. In a large circus there would be several trains. The initial train would be the "flying squadron" bearing the cook house, horse tents, menagerie, and steam calliope, having departed while the crowds were still watching the last performance in the previous town. At intervals would follow the "canvas train" and "lumber train" bearing construction materials in the order they would be needed. Wagons were pulled by baggage horse teams to the showgrounds, directed by arrows chalked on posts and trees by an advance man.

The showgrounds became a scene of organized confusion: acres of canvas and a forest of poles were assembled before swarms of curious people—affectionately called

"lot lice" by showmen. Then "parade call" was trumpeted, and performers, musicians, animal attendants, wardrobe crews, drivers, and brakemen assembled for the grand free street parade that was usually scheduled for 11:00 AM. Following the bugle brigade heralding the grand event, there was a long procession of horses, flag bearers, bands on magnificent wagons, allegorical tableaus, clowns, knights in armour, beautiful ladies on steeds, Roman chariots, chimes, bells, a band organ, cage after cage of wild animals (some open to view and others closed to prompt curiosity), cowboys, Indians, and a long line of highly caparisoned elephants shuffling along trunk-to-tail. The traditional finale to the circus parade was the Pied Piper of the circus, the steam calliope: 32 steam whistles, keyboard operated, powered by coal fire and boiler, hissing steam and smoke, and blasting out such favourites as "Go Tell Aunt Rhodie" and "The Sidewalks of New York." Under steam pressure of from 80 to 100 pounds per square inch, its tones carried four miles against a breeze. After two shows daily and the teardown, which took place at night, the wagons and teams followed flares to the train, where they rolled back onto the flatcars to disappear into the night.

The calliope

The big top. The origin of the circus tent is believed to have occurred in 1825 on the itinerating show of the American J. Purdy Brown. At first tents were very small, housing one ring and a few hundred seats. In their heyday, however, after circuses had begun to exhibit simultaneously in two (1872) and then three (1881) rings, the great American tented circuses played under what could be called canvas coliseums. The big top of the Ringling Bros. and Barnum & Bailey Circus covered the equivalent of a hectare, or more than two acres; supported by several centre poles that rose 65 feet (nearly 20 metres), it sheltered from 10,000 to 12,000 people. From portable bleachers, crowds could watch as many as seven rings and "stages" (platforms set between and at the ends of the three rings) at the same time, in addition to the aerial acts above. A typical big top of standard American circuses such as Hagenbeck–Wallace or Cole Bros. would be somewhat smaller, housing about 5,000 seats. European and British circuses generally retained the one-ring format, although their programs were often of the highest calibre and their tents might also seat as many as 5,000 spectators. In order to maintain the one-ring design while expanding the area beneath the tent, the European tent was designed with the four centre poles forming a square instead of a single-file line as with American big tops.

One or three rings

Just as some European circuses, such as Italy's Circo Americano, attempted to emulate the American pattern and exhibited simultaneously in three rings, in the second half of the 20th century there was increasing interest among American showmen in adopting, or reverting to, the more intimate, less confusing one-ring format. The Big Apple Circus of New York City, one of the most elegant shows ever seen in the United States, performed in a single ring inside a tent that seated only about 1,600 spectators.

Winter quarters. In the United States and to some extent in Europe, circuses annually retired to winter quarters to refurbish for another season. Among the cities that became identified as winter-quarters towns were Peru, Ind., which sheltered Hagenbeck–Wallace and other shows; Baraboo, Wis., the winter home for the circus of the Ringling Bros. and their cousins the Gollmar Bros.; and Bridgeport, Conn., which for nearly 50 years served as headquarters for Barnum's "Greatest Show on Earth," until the Ringlings moved the operations of the combined show to Sarasota, Fla., in 1927.

VARIATIONS ON THE CIRCUS THEME

Wild West shows. Wild West shows, which were sometimes attached to circuses, emphasized displays and events of America's old West. A Wild West show usually presented its exhibition in a large open field surrounded by bleachers protected by a canvas canopy. Typically, such shows featured American Indian ceremonies; cowboys who engaged in broncobusting, roughriding, roping, and sharpshooting; and dramatic representations of life on the frontier and Indian attacks on wagon trains or stagecoaches, whose occupants were saved by the timely arrival of the U.S. cavalry. Although Barnum had added such an exhibition to his circus as early as 1876, the credit for establishing the Wild West show as a separate entertainment goes to the former cavalry scout William F. "Buffalo Bill" Cody (1846–1917) and his partner W.F. "Doc" Carver, who launched their own Wild West & Congress of Rough Riders of the World in 1883. Pawnee Bill's Wild West and Miller Bros. 101 Ranch Real Wild West were prominent competitors of Buffalo Bill over the years. The famous riflewoman Annie Oakley, "Little Miss Sure-Shot," gained her fame as a star of Wild West shows. Many film stars were associated with them, too, including Tom Mix and Will Rogers. The last Wild West show was Colonel Tim McCoy's Wild West of 1938.

Carnivals. The public sometimes confuses circuses with carnivals, but they are quite different, even though both are traveling amusements. Instead of presenting a unified performance in one large enclosure, a carnival presents a midway lined with independent tented sideshows, concessions, special attractions, and rides or thrill events in which the patrons are participants, not spectators. Carnivals usually stay a full week or longer in any one location. In their modern American form, carnivals originated around the end of the 19th century when such rides as the Ferris wheel and steam-operated merry-go-round (carousel) became popular. Carnivals became standard features of state and county fairs in the United States.

Ferris wheels and carousels

THE STATE OF THE ART

Early 20th-century changes. Circuses in Europe began to encounter economic difficulties in the period after World War I, when foreign travel was inhibited by passport formalities, customs duties, quarantine restrictions, and currency regulations. For large companies with much equipment the difficulties were particularly acute. In order to evade inflation and crisis at home, one German circus toured South America in 1923 and 1934.

In the 1920s the circus in Britain declined. It was spectacularly revived by Bertram Mills, a coach builder, who introduced the greatest international circus stars to the British public at Olympia, London, and ran the only tenting circus to travel by rail in England.

Meanwhile, in the United States the circus was also encountering difficulties. During the Great Depression the Ringling empire collapsed; and the federal government, in order to give employment to out-of-work performers, organized a Works Progress Administration Circus—the only example of a state-run circus ever seen in the United States. In 1944 a disastrous fire in the Ringling big top, which took 168 lives and left hundreds of other spectators burned and injured, added to the woes of American circus proprietors. By the 1950s, faced with stiff competition from motion pictures and especially television, American circuses were generally declining; and in 1956 John Ringling North, citing economic and labour problems, announced that the "Greatest Show on Earth" would abandon its big top and in the future perform only in permanent exhibition halls and sports arenas. For many this announcement signaled the imminent demise of the circus.

By then, too, the spectacular street parade had long since disappeared, and most other American circuses were smaller and again traveling by road. The era of the truck show or motorized circus had dawned in the United States in 1918 with the short-lived Great United States Motorized Circus. Motor transport proved successful in the 1920s for Downie Bros. Circus, Seils-Sterling Circus, and some others. At first there was a tendency within the profession to belittle circuses transported by truck, but the 1930s produced several outstanding shows that moved by motor transport, including one owned by Tom Mix. Motorization enabled the canvas-tent circus to survive and continues to do so, only Ringling Bros. still moving the bulk of its show by rail.

Moving by truck

Circuses never entirely discontinued the use of indoor facilities for their exhibitions. Especially in Europe, circuses continued to perform in buildings throughout the heyday of the canvas shows—at the Circus Schumann in Copenhagen, for example, and at the venerable Cirque d'Hiver in Paris, which dates from 1852. Even the greatest

tent shows opened their seasons in metropolitan buildings, enabling them to extend their performances into the winter months. Such was the case with the annual opening of Bertram Mills Circus at Olympia in London, Ringling Bros. Circus at Chicago's Coliseum, and Barnum & Bailey at Madison Square Garden in New York City. In Russia and certain other areas of the former Soviet Union, the circus was regarded as an art form and received lavish state support. Nearly every city of any size boasts a permanent circus building. The New Moscow Circus possesses two additional rings, for water and ice shows, that can be separately raised by a mechanism from below to replace the circus ring as occasion demands. Most major American and western European circuses continue to tour under canvas, however, and, even in Russia and eastern Europe, tent circuses are by no means uncommon.

Preservation of the past. During the 20th century, several schools around the world were established to train students in the art of circus skills. In Russia a professional school for the training of circus artists has been associated with the Moscow Circus since 1929. After four years of rigorous course work, graduates are assigned to the nearly 100 circuses that perform throughout the country. In 1985 the French Ministry of Culture and Communication opened a professional school for artists, the High School of Circus Arts (l'Ecole Supérieure des Arts du Cirque), at Châlons-sur-Marne. The National Circus School of Montreal is the only private school in North America to offer training in a wide range of circus arts, although there are a number of schools and universities in the United States that provide instruction in specific aspects of the circus. One of the best known of these was the Ringling organization's "Clown College," located in Venice, Fla., which was established in 1968 and closed in 1997. Other American institutions with programs devoted to the circus include Florida State University at Tallahassee, whose Flying High Circus (begun in 1947) draws performers exclusively from the student body; Circus Smirkus in Greensboro, Vt., which enrolls children from around the world to collaborate with professional circus coaches; the Gamma Phi Circus of Illinois State University at Normal, which was established in 1929 and is the oldest college circus program in the country; and the University of Virginia at Charlottesville, which offers the only college-accredited courses on circus history.

Circus schools

The presence of these schools reflects a growing interest in preserving the colourful past of the circus. Pursuing this goal are collectors and historians throughout the world, as well as associations, including the Circus Fans Association (England and the United States), the Club du Cirque (France), the Society of Friends of the Circus (Germany and Austria), the Circus Historical Society, the Circus Model Builders Association, the Windjammers, the Ringling Museum of the Circus, and the International Clown Hall of Fame (all in the United States). At Baraboo, Wis., the extensive Circus World Museum is operated by the State Historical Society. Each July a train of authentic circus railroad cars transports more than 80 restored circus parade wagons from Baraboo to Milwaukee, where they are joined by hundreds of privately owned baggage horses for a parade through the streets of the city. At Bridgeport, Conn., the Barnum Museum features exhibits related to the circus and the life of Barnum. Most major European collections of circus materials remain in private hands, although there are important holdings available to researchers at such institutions as the British Library in London, the library and museum of the Paris Opéra, and the Museum of Circus Art attached to the circus in St. Petersburg, Russia.

Circus museums

Contemporary developments. For all its emphasis on tradition and discipline, the circus has always been a dynamic, growing institution. This was evident in late 20th-century circuses such as Canada's Cirque du Soleil (founded 1984). These companies employed no animals in their performances and instead integrated acrobatics and feats of daring into shows built around a single theme or story line. Performances also incorporated contemporary music and lighting effects and were seen on proscenium stages rather than in circus rings.

The circus also became an increasingly global form of entertainment during the latter half of the 20th century. Particularly notable were the circuses of Africa, India, Spain, Brazil, and Mexico, many of which were characterized by acrobatic and athletic exhibitions with traditions rooted in religion and folklore. The circuses of China, which thrived after receiving government funding beginning in 1949, were especially renowned for unique acts emphasizing balance and coordination, such as the "Peacock Bicycle," which featured a human pyramid of 17 people atop a single bicycle. By 2000 there were more than 250 circus troupes in China, many of which performed throughout the world.

Various international circuses may each reflect a distinct national flavour, but all circuses bridge cultural boundaries, as the circus itself is essentially a nonverbal entertainment. One might term the circus the most democratic of entertainments, because, no matter what the spectator's age or level of sophistication, there is always something interesting and amusing. For these and other reasons, the circus remains preeminently a "live" entertainment, whose pleasures and nuances can never be fully captured on film or television. It is an institution that continues to endure at the turn of the 21st century, thrilling people of all nations. (R.L.P/A.D.H.C./A.H.Sa./Ed.)

KASSON, *Buffalo Bill's Wild West: Celebrity, Memory and Popular History* (2000); HELEN STODDARD, *Rings of Desire: Circus History and Representation* (2000); and JAMES W. COOK, *The Arts of Deception: Playing with Fraud in the Age of Barnum* (2001). English circus traditions are discussed in A.H. SAXON, *The Life and Art of Andrew Ducrow & the Romantic Age of the English Circus* (1978). Russian circus history is treated in DAVID LEWIS HAMMARSTROM, *Circus Rings Around Russia* (1983).

Individual acts and attractions are described in A.H. SAXON, *Enter Foot and Horse: A History of Hippodrama in England and France* (1968); ANTONY HIPPISLEY COXE, *A Seat in the Circus*, rev. ed. (1980); DAVID CARLYON, *Dan Rice: The Most Famous Man You've Never Heard Of* (2001); and DONNALEE FREGA, *Women of Illusion: A Circus Family's Story* (2001). The activities of famous impresarios are presented in GEORGE SANGER, *Seventy Years a Showman* (1908, reissued 1966); GEORGE SANGER COLEMAN and JOHN LUKENS, *The Sanger Story: The Story of His Life with His Grandfather "Lord" George Sanger* (1956, reissued 1974); CYRIL BERTRAM MILLS, *Bertram Mills Circus: Its Story* (1967, reissued 1984); DAVID LEWIS HAMMARSTROM, *Big Top Boss: John Ringling North and the Circus* (1992); and PHINEAS T. BARNUM, *The Life of P.T. Barnum, Written by Himself* (1855; also published as *The Life of P.T. Barnum*, 2000), the latest edition of Barnum's famous autobiography, which is faithful to the original unrevised text. Among the better books devoted to specific aspects and events of circus history are RICKY JAY, *Learned Pigs and Fireproof Women* (1986, reissued 1998), a classic study of sideshows and their attractions; STEWART O'NAN, *The Circus Fire: A True Story* (2000), which investigates a devastating event in circus history, the Hartford fire of 1944; and ERNEST ALBRECHT, *The New American Circus* (1995), which explores contemporary circuses such as the Cirque du Soleil. For further research on the subject, see RAYMOND TOOLESCOTT, *Circus and Allied Arts: A World Bibliography*, 4 vol. (1958–71). (A.H.Sa./Ed.)

Cities

The name city is given to certain urban communities by virtue of some legal or conventional distinction. It also refers to a particular type of community, the urban community, and its generic culture, often called "urbanism." In legal terms, in the United States, for example, a city is an urban area incorporated by special or general act of a state legislature. Its charter of incorporation prescribes the extent of municipal powers and the frame of local government, subject to constitutional limitation and amendment. In common usage, however, the name is applied to almost every American urban centre, whether legally a city or not, and without much regard to actual size or importance. In Australia and Canada, city is a term applied to the larger units of municipal government under state and provincial authority respectively. New Zealand has followed British precedent since the abolition of the provinces in 1876; the more populous towns are called boroughs under the Municipal Corporations Act of 1933 and earlier legislation. In the United Kingdom itself, city is merely an official style accorded towns either in their historical identity as episcopal sees or as the beneficiaries *honoris causa* of a special act of the crown (the first town so distinguished was Birmingham in 1889). Except for the ancient City of London (an area of about 677 acres in central London under the jurisdiction of the lord mayor), the title has no significance in local government in the United Kingdom. In all the other countries of the world, the definition of city similarly follows local tradition or preference.

City government is almost everywhere the creation of higher political authority, state or national. Some European countries have adopted general municipal codes which permit centralized administrative control over subordinate areas through a hierarchy of departmental prefects and local mayors. Socialist countries also employ a hierarchical system of local councils that correspond to, and are under the authority of, governing bodies at higher levels of government. In English-speaking countries, devolution of powers to the cities occurs through legislative acts that delegate limited self-government to local corporations.

As a type of community, the city may be regarded as a relatively permanent concentration of population, together with its diverse habitations, social arrangements, and supporting activities, occupying a more or less discrete site, and having a cultural importance that differentiates it from other types of human settlement and association. In its elementary functions and rudimentary characteristics, however, a city is not clearly distinguishable from a town or even a large village. Mere size of population, surface area, or density of settlement are not in themselves sufficient criteria of distinction, while many of their social correlates (division of labour, nonagricultural activity, central-place functions, and creativity) characterize in varying degree all urban communities from the small country town to the giant metropolis.

The history of cities

INITIAL REQUIREMENTS FOR URBAN DEVELOPMENT

Environmental characteristics of early settlements

It was no accident that the earliest of man's fixed settlements are found in the rich subtropical valleys of the Nile, the Tigris, the Euphrates, the Indus, and the Yellow rivers or in such well-watered islands as Crete. Such areas provided favourable environmental factors making town living relatively easy: climate and soil favourable to plant and animal life, an adequate water supply, ready materials for providing shelter, and easy access to other peoples. Although man with ingenuity has been able to utilize almost any environment for town living, environments favourable to the production of food and shelter and ease and comfort of living clearly possessed advantages for the beginnings of urban life.

A distinguished historian, Ralph E. Turner, has suggested that various preurban developments made possible the technology and organization permitting city life. These included psychological elements such as recognition of "in-group" versus "out-group" interests; the notion of a universe, even if mysterious, that could be controlled; and belief in the existence of a soul. The in-group and out-group differentiation provided a basis for respect for the rights of others and for life, property, and family values. The notion that man could control the world in which he lived was of great importance, even if the methods of control were primitively based on magic and religion. The belief in a soul helped make life on Earth more acceptable, even if hard, for life became then only an incident in a long journey.

Preurban developments that paved the way for urban life also included such factors as traditionalism, a power structure, and a form of economic as well as social organization. Traditionalism lay in the acceptance and transmission of what had worked in the life of the group and was therefore "right" and to be retained. Some form of power structure involving subordination was necessary, for leadership was a vital element in urban living in that it was essential to the performance of such vital functions as sustenance, religious practices, social life, and defense. Also prerequisite to group life were new economic and social institutions and groupings such as property, work, the family, a system for distribution of commodities and services, record keeping, police for internal security, and armed forces for defense.

New value orientations and ideologies may also have affected the course of urbanization, though their importance is still highly conjectural. There are those who have felt that urbanization depended on a new outlook; it meant that people had become more rationalistic (and less mystical); it meant that, for purposes of building, they were more willing and able to defer immediate for more desirable later gratification; it meant more emphasis on achievement and success as distinguished from status and prestige; it meant a cosmopolitan as distinguished from a parochial outlook; and it meant that relations between people were more ordered, impersonal, and utilitarian, rather than only personal and sentimental.

EARLY CITIES

Ancient world. About 10,000 years ago in the Neolithic Period, man achieved relatively fixed settlement, but for perhaps 5,000 years such living was confined to the semipermanent peasant village—semipermanent because, when the soil had been exhausted by the relatively primitive methods of cultivation, the entire village was usually compelled to pick up and move to another location. Even when the village prospered in one place and the population grew relatively large, the village usually had to split in two, so that all cultivators would have ready access to the soil.

The evolution of the Neolithic village into a city took at least 1,500 years—in the Old World from 5000 to 3500 BC. The technological developments making it possible for man to live in urban places were, at first, mainly advances in agriculture. Neolithic man's domestication of plants and animals eventually led to improved methods of cultivation and stock breeding and the proliferation of the crafts, which in turn eventually produced a surplus and freed some of the population to work as artisans, craftsmen, and service workers.

Transportation development

As human settlements increased in size, by reason of the technological advances in irrigation and cultivation, the need for improving the circulation of goods and people became ever more acute. Pre-Neolithic man leading a nomadic existence in his never-ending search for food moved largely by foot and carried his essential goods with the help of his wife and children. Neolithic man, upon achieving the domestication of animals, used them for transportation as well as for food and hides. Then came the use of draft animals in combination with a sledge equipped with runners for carrying heavier loads. The major technological achievement in the early history of transportation, however, was obviously the invention of the wheel, used first in the Tigris–Euphrates Valley about 3500 BC and constructed first with solid materials and only later with hubs, spokes, and rims. Wheels, to be used efficiently, required roads, and thus came road building, an art most highly developed in ancient times by the Romans. Parallel improvements were made in water transport—with rafts, dugouts, the Egyptian reed float, eventually wooden boats, and of course canals used for both navigation and irrigation. (Ed.)

By 3500 BC urban populations were distinguished by literacy, technological progress (notably in metals), social controls, political organization, and emotional focus (formalized in religious-legal codes and symbolized in temples and walls). Such places, dated by historical means, existed on the Sumerian coast at Ur and in the Indus Valley at Mohenjo-daro during the 3rd millennium and, before 2000 BC, had also appeared in the Nile and Weiho valleys. Cities proliferated along overland trade routes from Turkestan to the Caspian and then to the Persian Gulf and eastern Mediterranean. Their economic base in agriculture (supplemented by trade) and their political-religious institutions made for an unprecedented degree of occupational specialization and social stratification. From central vantage points, cities already gave some coherence and direction to life and society in their hinterlands.

The growth of cities, however, was by no means the inevitable outcome of a succession from primitive life to civilization. As S. Piggott pointed out in "Role of the City in Ancient Civilizations" (in *Metropolis in Modern Life*, ed. by E.M. Fisher [1955]), an alternative and, in some ways, inimical type of community had arisen in the steppe-lands of Asia based upon animal husbandry: the nomadic encampment. Like their urban contemporaries, the nomads were no longer "primitive" men. In addition to pastoralism, they had developed great oral traditions, abstract art styles, and numerous crafts, albeit no formal architecture. Led by warrior chiefs, these self-sustaining migratory peoples encroached upon the settled agricultural-trading areas to the south.

During the 2nd millennium the Indus civilization was engulfed by an onslaught of Aryan nomads, while other peoples, using horses and chariots, penetrated the urban heartland from Mesopotamia to Egypt. In these circumstances of prolonged upheaval, survival required the perfection of warlike arts and predatory supply systems, which transformed the urban communities into paramilitary states—*e.g.*, the Hittite, Egyptian, and Mycenaean empires. Citizenship, though still a ceremonial service, was increasingly associated with the bearing of arms. After 1200 BC even the city-empires (a city-camp hybrid) lapsed into chaos and disorder until the lifting of the Hellenic "dark ages" during the 8th century BC and the transplanting of the syncretic city-state beyond the eastern Mediterranean by Phoenicians and Greeks.

Autonomous and dependent cities. The heterogeneous peoples that created the Greco-Roman world inherited a technological and nonmaterial culture from southwestern Asia which helped mollify barbarism and nourish the growth of cities. Their trading colonies, from the Crimea to Cadiz, eventually brought the entire Mediterranean within the orbit of civilization. It was in the Greek city-state, or *polis*, however, that the city idea reached its peak. Originally a devout association of patriarchal clans, the *polis* came to be a small self-governing community of citizens in contrast to the Asian empires and nomadic hordes. For citizens, at least, the city and its laws constituted a moral order symbolized in magnificent buildings and public assemblies. It was, in Aristotle's phrase, "a common life for a noble end."

The Greek *polis*

When the old exclusive citizenship was relaxed and as new commercial wealth surpassed that of the older landed citizenry, social strife at home and rivalry abroad gradually weakened the common life of the city-republics. The creativity and variety of the *polis* gave way before the unifying forces of king-worship and empire epitomized by Alexander the Great and his successors. To be sure, many new cities were planted between the Nile and the Indus through which the amenities and forms of city-culture were carried back to the east, but the city itself ceased to be an autonomous body politic and became a dependent member of a larger political-ideological whole.

The Romans, who fell heirs to the Hellenistic world, transplanted the city into the technologically backward areas beyond the Alps inhabited by pastoral-agricultural Celtic and Germanic peoples. But, if Rome brought order to civilization and carried both to barbarians along the frontier, it made of the city a means to empire (a centre for military pacification and bureaucratic control) rather than an end in itself. The enjoyment of the imperial Roman peace entailed the acceptance of the status of *municipium*—a dignified but subordinate rank. Initiatives passed to the centre; and, in the east, the culture of provincial cities became imitative, their politics trivial. They contributed little to the larger economic life beyond the needs of their social elites and the payment of taxes; they tapped the surpluses created by local agriculture and trade in rents and tribute. As Roman citizenship became more universal and formal, the idea of public duty gave way to private ambition. Municipal functions atrophied; and, except for their fiscal duties, it was in a passive role that the city survived into the Byzantine era.

Roman citizenship and provincial cities

MEDIEVAL AND EARLY MODERN ERA

Medieval cities: from fortress to emporium. In Latin Europe neither political nor religious reforms could sustain the Roman regime. The breakdown of public administration and the breach of the frontier led to a revival of parochial outlook and allegiance, but their focus was not upon the city. Community life now centred on the fortress (*burgum*) or castle (*castellum*); the term city (*civitas*) was

attached to the precincts of the episcopal throne, as in Merovingian Gaul.

Early medieval society was a creation of camp and countryside to meet the local imperatives of sustenance and defense. With Germanic variations on late Roman forms, communities were restructured into functional estates, each of which owned formal obligations, immunities, and jurisdictions. What remained of the city was comprehended in this feudal-manorial order, and the distinction between town and country was largely obscured when secular and ecclesiastical lords ruled over the surrounding counties (*comté, Grafschaft*) as the vassals of mock emperors or barbarian kings. Social ethos and organization enforced submission to the common good of earthly survival and heavenly reward; the true city, *civitas Dei,* was not of this world. The attenuation of city life in most of northern and western Europe was accompanied by provincial separatism, economic isolation, and religious otherworldliness. Not before the cessation of attacks by Magyars, Norsemen, and Saracens did urban communities again experience sustained growth.

Recovery after the 10th century was not confined to the city or to any one part of Europe. The initiatives of monastic orders, seigneurs, or lords of the manor, and merchants alike fostered a new era of increased tillage, enlarged manufacture, money economy, the growth of rural population, and the founding of "new towns," as distinguished from those "Roman" cities that had survived from the period of Germanic and other encroachments. In almost all the medieval towns the role of the merchant was central: his needs and aspirations had a catalytic effect and, largely as a consequence of mercantile enterprise in the long-distance staple trade, cities were to flourish once more. Under commercial stimulus, feudal obligations were relaxed and European society was made over anew by the city and the marketplace in pursuit of self-government and economic gain.

Before the year 1000 contacts with rich Byzantine and Islāmic areas in the Levant had revitalized the mercantile power in Venice, which commanded the profitable route to the Holy Land during the Crusades. Meanwhile, merchant communities had attached themselves to the more accessible castle towns and diocesan centres in northern Italy and on the main travelled routes to the Rhineland and Champagne. They later appeared along the rivers of Flanders and northern France and on the west–east road from Cologne to Magdeburg.

Rise of civic autonomy

It was no coincidence that the 12th and 13th centuries, which saw the founding of more new towns than any time between the fall of Rome and the Industrial Revolution, also witnessed a singular upsurge toward civic autonomy. Throughout western Europe, towns acquired various kinds of municipal institutions loosely grouped together under the designation "commune." Broadly speaking, the history of the medieval towns is that of the merchant elites seeking to free their communities from lordly jurisdiction and to secure their government to themselves. Wherever monarchical power was strong, they had to be content with a municipal status, but elsewhere they created city-states. Taking advantage of renewed conflict between popes and emperors, they allied with local nobility to establish communal self-government in the largest cities of Lombardy, Tuscany, and Liguria. In Germany the city councils sometimes usurped the rights of higher clergy and nobility; Freiburg im Breisgau obtained its exemplary charter of liberties in 1120. The movement spread to Lübeck and later to the net of Hanse towns on the Baltic and North seas, touching even the Christian "colonial" towns east of the Elbe–Saale rivers. In the 13th century the "Great Towns" of Bruges, Ghent, and Ypres, creditors of the counts of Flanders, virtually governed the entire province. In France, revolutionary uprisings, directed against nobility and clergy, sometimes established free communes, but most communities were perforce content with a franchise from their sovereign more limited than those enjoyed by English boroughs under the Norman Conquest. Finally, the corporate freedom of the towns brought emancipation to individuals. When bishops in the older German cities treated newcomers as serfs, the emperor Henry V affirmed the principle *Stadtluft macht frei* ("City air brings freedom") in charters for Speyer (or Spires) and Worms; "new towns" founded on the lands of lay and clerical lords offered freedom and land to settlers who took up residence for more than "a year and a day." In France the *villes neuves,* or "new towns" (*e.g.,* Lorris), and *bastides* (*e.g.,* Montauban) likewise conferred rights on servile persons.

In the 14th century, the urban movement subsided as Europe entered on a period of political anarchy and economic decline that did not much abate before the 16th century. At a time when local specialization and interregional exchange required more liberal trade policies, craft protectionism and corporate particularism in the cities tended to hobble the course of economic growth. The artisan and labouring classes, moreover, now challenged the oligarchical rule of the wealthy burghers and gentry, disrupted local government, and ultimately destroyed the basis of civic autonomy: prolonged social warfare led to "popular" despotisms and fiscal bankruptcy. Visitations of plague, fanatical crusades against heresy, and Turkish encroachments on the routes to Asia worsened conditions in town and country alike. Europe turned inward upon itself; and, except for a few large centres, activity in the marketplace was depressed: the cities surrendered their liberties and their population. These centuries of decline were relieved only by the slow process of individual emancipation and the cultural efflorescence of the Renaissance, which laid the intellectual basis for the great age of geographical and scientific discovery exemplified in the new technologies of gunpowder, mining, printing, and navigation. Not before the triumph of princely government, in fact, did political allegiance, economic interests, and spiritual authority again become centred in a viable unit of organization, the absolutist nation-state.

The city and the nation-state. The virtue of absolutism in the early modern period lay in its ability to utilize the new technologies. Through the centralization of power, economy, and belief it brought order and progress to Europe and provided a framework in which individual energies could once more be channeled to a common end. While the nation stripped the cities of their remaining pretensions to political and economic independence (symbolized in their walls and tariff barriers), it created larger systems of interdependence in which territorial division of labour could operate. Though new mercantilist policies built up national wealth, they did not necessarily foster the growth of cities. All too often the wealth of nations was dissipated in war. Much of the income produced in town and country went to bolster the monarch's power and advertise his fame; the splendour of court life and the baroque glory of palaces and churches were paid for by merchant enterprise and the toil of peasants and craftsmen. Only in colonial areas, notably the Americas, did the age of expansion see the planting of many new cities, and it is significant that the capitals and ports of the colonizing nations experienced their most rapid growth during these years. Under absolutist regimes, a few large political and commercial centres grew at the expense of smaller outlying communities and the rural hinterlands.

Technology and the centralization of power

By the 18th century, the mercantile classes were increasingly disenchanted with monarchical rule. They resented their lack of political influence and assured prestige. They objected to outmoded regulations that hindered their efforts to link commercial operations with the systematic improvement of production. Eventually, they would unite with other dissident groups to curb the excesses of absolutism, erase the vestiges of feudalism, and secure a larger voice in the shaping of public policy. In northwestern Europe, where these liberal movements went furthest, the city populations and their bourgeois elites played a critical role out of all proportion to their numbers. Elsewhere, as in Germany, the bourgeois were more reconciled to existing regimes or, as in northern Italy, had assumed a passive if not wholly parasitical role.

With the exceptions of Great Britain and the Netherlands, however, the proportion of national populations resident in urban areas nowhere exceeded 10 percent. As late as 1800 only 3 percent of world population lived in towns of more than 5,000 inhabitants. No more than 45

cities had populations over 100,000, and of these fewer than half were situated in Europe. Asia had almost two-thirds of the world's large-city population, and cities such as Peking, Canton, and Edo (now Tokyo) were larger than ancient Rome or medieval Constantinople at their peaks. Clearly, the mere presence of large cities or merchant elites anywhere in the world did not ensure the development of a dynamic social economy: the decisive factor was industrialism.

INDUSTRIALIZATION AND THE MODERN WORLD

Before 1800, innovations in agricultural and manufacturing techniques had permitted a singular concentration of productive activity close to the sources of mechanical power—water and coal. A corresponding movement of population was accelerated by the perfection of the steam engine and the superiority of the factory over preindustrial business organization. From the standpoint of economy, therefore, the localization of differentiated but functionally integrated work processes near sources of fuel was the mainspring of industrial urbanism. Under conditions of belt-and-pulley power transmission, urban concentration was a means of (1) minimizing the costs of overcoming frictions in transport and communications and (2) maximizing internal economies of scale and external economies of agglomeration. Although the intellectual and social prerequisites for industrialization were not uniquely present in any one nation, an unusual confluence of commercial, geographic, and technological factors in Britain led to far-reaching changes in such strategic activities as textiles, transport, and iron. Britain became "the workshop of the world" and London its "head office." Differentiation went so far that the cotton, woollen, and iron districts became more specialized and productive, each proceeding within its own cycle of technical and organizational change. By the mid-19th century, similar if less comprehensive industrial organization was evident in parts of France, the Low Countries, and the northeastern United States.

Industry and urban concentration

The concentration of the manufacturing labour force in "mill towns" and "coke towns" gradually undermined traditional social structures and relations. Age-old problems of public order, health, housing, utilities, education, and morals were aggravated by the influx of newcomers from the countryside. High rural birth rates combined with the industrialization of agriculture to release not only the country's foods and fibres but its children as well. Though the lowering of mortality in the 19th century was later offset by declines in fertility, the population of the more industrialized nations boomed into the 20th century, and the greater part of the increment migrated to the larger towns. The outcome was rural depopulation and the urbanization of society. Local institutions, often of medieval origin, were unable to cope with conditions that exaggerated poverty, disrupted family life, and complicated personal adjustment. Piecemeal reforms did little to improve the new milieu because, in the last analysis, the "city problem" arose not so much from the lack of public authority as from an unwillingness to pay the costs of social planning and improvement. Generations of urbanites experienced a continuing disorganization of their lives and work before the rising productivity of machines and increasing popular pressures on government could arrest the worst effects of this profound transformation. Slowly and painfully, the city's population adapted to its norms and enjoyed its satisfaction. New economic and cultural opportunities in the city evidently compensated for its congestion and strain.

Social disruption and reform

In the century after 1850, world population doubled, and the proportion living in cities of more than 5,000 inhabitants rose from less than 7 percent to almost 30 percent. Between 1900 and 1950 the population living in large cities (100,000 plus) rose by 250 percent, the rate of increase in Asia being three times that of Europe and the United States. Nevertheless, the pattern of industrial urbanization (an overwhelmingly nonagricultural economy organized in a hierarchical system of different-sized cities ranging from one or more metropolitan centres at the top to a broad base of smaller-sized cities underneath) was still largely confined to the economically advanced areas: Europe, North America, Japan, and to a lesser extent Australasia. Meanwhile, industrial urbanism had entered its metropolitan phase. The widespread use of cheap electric power, the advent of rapid transit and communications, new building materials, the automobile, and rising levels of per capita personal income had led to some relaxation of urban concentration. City dwellers began moving out from older downtown areas to suburbs and satellite communities where conditions were thought to be less wearing on nerves and bodies. Rising central-area land values, traffic congestion, increased taxation, and festering slums reinforced the exodus. At the city's core the composition of the resident population came to include growing proportions of the aged, minority groups, and the very poor.

In the reshaping of the 20th-century city, advantages for residence and consumption probably played a more decisive role than advantages for production. Thus, while its advantages for manufacturers have diminished, the city remains the only feasible locus for the mass of specialized service activity that forms so large a part of the modern economy: the city offers maximum access to people. The spread of the city, however, has further weakened the vitality of local government: the difficulty of defining appropriate administrative boundaries has been added to the older problems of powers and finance. The task is to find viable forms of government for vast metropolitan districts, sometimes identified as conurbations, which sprawl across the countryside without unity or identity. (E.E.La./Ed.)

Urban planning

Urban planning and redevelopment is aimed at fulfilling social and economic objectives that go beyond the physical form and arrangement of buildings, streets, parks, utilities, and other parts of the urban environment. Urban planning takes effect largely through the operations of government and requires the application of specialized techniques of survey, analysis, forecasting, and design. It may thus be described as a social movement, as a governmental function, or as a technical profession. Each aspect has its own concepts, history, and theories. Together they fuse into the effort of modern society to shape and improve the environment within which increasing proportions of humanity spend their lives: the city.

THE DEVELOPMENT OF URBAN PLANNING

Early history. There are examples from the earliest times of efforts to plan city development. Evidence of planning appears repeatedly in the ruins of cities in China, India, Egypt, Asia Minor, the Mediterranean world, and South and Central America. There are many signs: orderly street systems that are rectangular and sometimes radial; divisions of a city into specialized functional quarters; development of commanding central sites for palaces, temples, and what would now be called civic buildings; and advanced systems of fortifications, water supply, and drainage. Most of the evidence is in smaller cities, built in comparatively short periods as colonies. Often the central cities of ancient states grew to substantial size before they achieved governments capable of imposing controls. In Rome, for example, the evidence points to no planning prior to late applications of remedial measures.

Manifestations of urban planning in the ancient world

For several centuries during the Middle Ages, there was little building of cities in Europe. There is conflicting opinion on the quality of the towns that grew up as centres of church or feudal authority, of marketing or trade. They were generally irregular in layout, with low standards of sanitation. Initially, they were probably uncongested, providing ready access to the countryside and having house gardens and open spaces used for markets and fairs or grazing livestock. But, as the urban population grew, the constriction caused by walls and fortifications led to overcrowding and to the building of houses wherever they could be fitted in. It was customary to allocate certain quarters of the cities to different nationalities, classes, or trades, as in cities of East Asia in the present day. As these groups expanded, congestion was intensified.

The physical form of medieval and Renaissance towns

and cities followed the pattern of the village, spreading along a street, a crossroad, in circular patterns or in irregular shapes—though rectangular patterns tended to characterize some of the newer towns. Most streets were little more than footpaths—more a medium for communication than for transportation—and even in major cities paving was not introduced until 1184 in Paris, 1235 in Florence, and 1300 in Lübeck. As the population of the city grew, walls were often expanded, but few cities at the time exceeded a mile in length. Sometimes sites were changed, as in Lübeck, and many new cities emerged with increasing population—frequently about one day's walk apart. Towns ranged in population from several hundred to perhaps 40,000 (London in the 14th century). Paris and Venice were exceptions, reaching 100,000.

Housing varied from elaborate merchant houses to crude huts and stone enclosures. Dwellings were usually two to three stories high, aligned in rows, and often with rear gardens or inner courts formed by solid blocks. Windows were small apertures with shutters, at first, and later covered with oiled cloth, paper, and glass. Heating improved from the open hearth to the fireplace and chimney. Rooms varied from the single room for the poor to differentiated rooms for specialized use by the wealthy. Space generally was at a premium. Privacy was rare and sanitation primitive.

Urban design in the Renaissance

During the Renaissance, however, there were conscious attempts to plan features, such as logistically practical circulation patterns and encircling fortifications, which forced overbuilding as population grew. As late as the 1860s, the radial boulevards in Paris had military as well as aesthetic purposes. The grand plan, however, probably had as its prime objective the glorification of a ruler or a state. From the 16th to the end of the 18th century, many small cities and parts of large cities were laid out and built with monumental splendour. The result may have pleased and inspired the citizens, but it rarely contributed to the health or comfort of their homes or to the efficiency of manufacturing, distribution, or marketing.

The planning concepts of the European Renaissance were transplanted to the New World. In particular, Pierre l'Enfant's plan for Washington, D.C. (1791), illustrated the strength and weakness of these concepts; it was a plan ably designed to achieve monumentality and grandeur in the siting of public buildings but was in no way concerned with the efficiency of residential, commercial, or industrial development. More prophetic of the layout of U.S. cities was the rigid, gridiron plan of Philadelphia, designed by William Penn (1682), with a layout of streets and lots (plots) adaptable to rapid changes in land use but wasteful of land and inefficient for traffic. The gridiron plan travelled westward with the pioneers, since it was the simplest method of dividing surveyed territory. Its special advantage was that a new city could be planned in the eastern offices of land companies and lots sold without buyer or seller ever seeing the site.

The New England town also influenced later settlement patterns in the United States. The central commons, initially a cattle pasture, provided a focus of community life and a site for meetinghouse, tavern, smithy, and shops. It became the central square in county seats from the Alleghenies to the Pacific and remained the focus of urban activity. Also from the New England town came the tradition of the freestanding, single-family house. Set well back from the street and shaded by trees, it had an ornamental front yard and a working backyard and became the norm of American residential development. This was in contrast to the European town house, with its party wall and tiny fenced backyard.

19th century. In both Europe and the United States, the surge of industry during the 19th century was accompanied by rapid population growth, unfettered individual enterprise, great speculative profits, and remarkable lapses of community responsibility. During this era, sprawling, giant metropolitan cities developed, offering wealth and adventure, variety and change. Their slums, congestion, disorder, and ugliness, however, provoked a reaction in which housing reform was the first demand. Industrial slums in European and American cities were unbelievably congested, overbuilt, unsanitary, and unpleasant. The early regulatory laws set standards that improved upon the slums of the time but seemed a century later to be impossibly low. Progress was very slow, for the rent-paying ability of slum dwellers did not make it profitable to invest in better housing for them. Housing improvement as an objective, however, recurred continually. Early significant improvements in public health resulted from engineering improvements in water supply and sewerage, which were essential to the later growth of urban populations.

Industrial slums

Toward the end of the 19th century, another effort to improve the urban environment emerged from the recognition of the need for recreation. Parks were developed to provide visual relief and places for healthful play or relaxation. Later, playgrounds were carved out in congested areas, and facilities for games and sports were established not only for children but also for adults, whose workdays gradually shortened.

Concern for the appearance of the city had long been manifest in Europe, in the imperial tradition of court and palace and in the central plazas and great buildings of church and state. In Paris, Georges-Eugène, Baron Haussman, became the greatest of the planners on a grand scale, advocating straight arterial boulevards, advantageous vistas, and a symmetry of squares and radiating roads. The resurgence of this European tradition had a counterpart in the "city beautiful" movement in the United States following Chicago's World Columbian Exposition of 1893. This movement expressed itself widely in civic centres and boulevards, contrasting with and in protest against the surrounding disorder and ugliness.

20th century. Early in the 20th century, during the sprawling growth of industrial cities, factories invaded residential areas, tenements crowded in among small houses, and skyscrapers overshadowed other buildings. To preserve property values and achieve economy and efficiency in the structure and arrangement of the city, the need was felt to sort out incompatible activities, to set some limits upon height and density, and to protect established areas from despoilment. Zoning (see below) was the result.

Consequences of developments in transportation

As transportation evolved from foot and horse to street railway, underground railway or subway, elevated railroad, and automobile, the new vehicles made possible tremendous urban territorial expansion. Workers were able to live far from their jobs, and complex systems of communications developed. The new vehicles also rapidly congested the streets in the older parts of cities. By threatening strangulation, they dramatized the need to establish orderly circulation systems of new kinds.

Metropolitan growth so intensified these and other difficulties that the people living in cities—who for the first time outnumbered the rural population in many countries—began to demand an attack upon all of these problems. In response, city planning by midcentury aimed not at any single problem but at the improvement of all aspects of the urban physical environment through unified planning of the whole metropolitan area. This introduced issues of national planning and in many countries brought city planning into the field of planning the nation's economic and social resources as a whole.

Goals of modern urban planning. The ultimate goals had always been social, even during the period when city plans themselves related only to physical change. They had been and continued to be deeply involved with intermediate economic objectives. The expression of the goals was, of course, coloured by the culture of the society seeking them. Of increasing weight was the goal of equality of opportunity and the redress of the grievances of disadvantaged minorities. Within this value system the physically oriented urban planning of the first half of the 20th century had evolved a set of environmental objectives that continued to be valid: (1) the orderly arrangement of parts of the city—residential, business, industrial—so that each part could perform its functions with minimum cost and conflict; (2) an efficient system of circulation within the city and to the outside world, using to the maximum advantage all modes of transportation; (3) the development of each part of the city to optimum standards, in terms of lot size, sunlight, and green space in residential areas,

Six objectives of urban planning

and parking and building spacing in business areas; (4) the provision of safe, sanitary, and comfortable housing in a variety of dwelling types to meet the needs of all families; (5) the provision of recreation, schools, and other community services of adequate size, location, and quality; (6) the provision of adequate and economical water supply, sewerage, utilities, and public services.

Even these superficially clear objectives, however, were not fully operational. They involve such terms as "adequate" and "high standard," which are relative rather than absolute, and change with new insights from experience or research (medical, psychological, social) and with new technological achievements. Inherent in the concept of city planning was the recognition that an ideal is not a fixed objective but will itself change, that the ideal city can be striven toward but never achieved. This turned the focus of planning away from the "master plan" and toward a stress upon the process and the directions of change.

PLANNING AND GOVERNMENT

As a normal and identifiable function of government, city planning for the physical environment has been recognized in Europe and the United States since the early years of the 20th century. The year 1909 was a milestone. It saw the passage of Britain's first town planning act and, in the United States, the first national conference on city planning, the publication of Daniel Burnham's plan for Chicago, and the appointment of Chicago's Plan Commission (the first official planning agency in the U.S. was in Hartford, Connecticut, in 1907). Germany, Sweden, and other European countries also developed planning administration and law at this time.

Varying approaches to the administration of planning

City planning as a government function involves the coordination of all governmental activities that bear upon community growth and change, especially those that influence private development, so that they all work toward comprehensive objectives. The place of the city-planning function in the structure of urban government has developed in different ways in different countries. On the continent of Europe, where municipal administration was strongly centralized, city planning became the sphere of an executive department with substantial authority. In Great Britain, the local planning authority was a local legislative body (the county or county borough in England and Wales, the county or burgh in Scotland), advised by a planning committee of local councillors and with a planning department to act in an executive and advisory capacity. In the United States, with its tradition of tripartite government, it was recognized that decisions of importance to community development were made both by the executive branch (mayor) and the legislative (council). Rather than impinge on the authority of either, planning was allotted to a separate commission, advisory to both, with no authority beyond the right to be consulted before any action affecting the plan was taken.

Zoning and subdivision controls. Zoning, the regulation of the use of land and buildings, the density of population, and the height, bulk, and spacing of structures, was the principal means of putting into effect a comprehensive scheme for land use. It is generally dated from the adoption of New York City's first comprehensive ordinance in 1916. Though zoning was used in Great Britain and other European countries, it was developed furthest in the United States. The first ordinances were simple regulations, intended to protect existing property values and preserve light and air. As planning itself broadened its objectives and evolved its techniques during the 1930s, zoning developed into a more precise and sensitive tool.

Parallel to the evolution of zoning in the United States was the development of subdivision controls—subjecting the initial laying out of vacant land to public regulation. It was realized, after bitter experience with suburban land speculations in the 1920s, that the interest of the owner and developer of raw land is sometimes temporary and purely financial, while the urban community must live with the results for generations afterward. Subdivision regulations in many United States cities specified that new streets conform to the overall city plan and that new lots be properly laid out for building sites. Some required the developer to give the land needed for streets, playgrounds, and school sites and to pay all or most of the cost of development of these facilities.

Zoning and subdivision control offered adequate controls over the growth of new parts of cities, where they were used by enlightened legislative bodies. It was realized, however, that they were insufficient to correct past mistakes and especially to bring about the rebuilding of the obsolete parts of cities.

Experimental new towns of the early 20th century

Large-scale planning. All over the Western world, in the first half of the 20th century, new towns were built, constituting a very small part of the total or urban growth but serving as experiments and as examples of what could be done. This was largely the product of England's garden-city movement, which proposed preplanned new cities, on land held by the community and limited to 30,000 population, complete with business services and employment centres and surrounded by permanent greenbelts of rural land. The initial experimental cities were undertaken in England by private initiative, motivated by a spirit of reform; Letchworth was started in the early 1900s and Welwyn Garden City in the 1920s.

The concept had substantial influence in the United States. Kingsport, Tennessee, was a new city built by industrial interests. Some of the design ideas were used in suburban real-estate developments, outstanding being that of Radburn, New Jersey, which pioneered the super-block scheme as the "town for the motor age." U.S. examples, however, omitted the community-ownership feature, and almost all omitted employment centres, balanced income groups, and effective greenbelts. The federal government undertook a few large-scale housing developments for immigrant industrial workers during World Wars I and II, as make-work projects during the depression of the 1930s, and as examples of sound urban design. During the 1960s a number of private-enterprise developments at the scale of new cities were undertaken, primarily integral to expanding metropolitan areas rather than as truly independent cities. Notable were Reston, Virginia, and Columbia, Maryland, both near Washington, D.C., and the Irvine Ranch area near Los Angeles.

Also during the 1930s a number of European countries, especially France, The Netherlands, Germany, and the Soviet Union, undertook the building of new towns as governmental enterprises. Most of them (except in the Soviet Union) were residential suburbs rather than complete urban units. During the period following World War II, many European countries made strides in the regulation of new growth and in planned rebuilding of bomb-torn city centres.

After World War II, Great Britain embarked on a bold program. It reorganized the planning districts of the country; established sweeping new powers over private land use, almost nationalizing the right to develop undeveloped land; and undertook to build new towns to receive population and industry from congested great cities, which were planned for building at lower densities. By 1960, 15 new towns were under way, but the national program had suffered reverses. At first, economic exigencies interfered with the relocation of industry suggested by long-range environmental planning, and some of the controls over private land development, which appeared to impede investment and construction, had to be relaxed. Most of the new towns, nevertheless, had become centres of rapid industrial and population expansion and constituted important new work in city plan effectuation.

Postwar urban redevelopment in the United States

By the early 1970s urban redevelopment and renewal in the United States had achieved some major successes in revitalizing the economy of central-city areas. Such programs were bitterly criticized, however, for displacing low-income families and for disregarding the network of social relationships that had meant more to these families than the squalor and danger of their physical shelter. Among the new programs evolved after the establishment of a new cabinet-level Department of Housing and Urban Development was the Model Cities program. This was an experiment, in several dozen U.S. cities, in attacking the problems of major blighted areas with massive federal financial aid. It included programs of physical improvement

coordinated with social and economic upgrading through job training, school improvement, encouragement of economic enterprise, and a complete panoply of self-help and outside-help measures aimed at reducing poverty and all of its adverse concomitants.

Planning jurisdictions. Where a single municipal government included all of an urban area, tools for physical planning and effectuation seemed, in the second half of the 20th century, to be approaching adequacy. This condition, however, was exceptional. In Europe and the Americas, the metropolitan area was the typical urban form, composed of many independent municipalities, with overlapping jurisdictions of counties, school districts, and special authorities. During this period, European countries were groping toward solutions of the metropolitan planning and development problem, with some progress in Great Britain, Scandinavia, the Federal Republic of Germany, and The Netherlands. In the 1950s a limited metropolitan government was established for Toronto, Ontario, with planning as an integral function. As late as the early 1970s metropolitan planning efforts in the United States were still largely ineffective. Planning agencies had little voice in the decisions of not only the separate cities and suburbs but also larger public agencies, such as state highway departments, sewer and water supply authorities, and port and airport authorities. The U.S. planning movement had not yet evolved the governmental machinery for reconciling in a democratic way the conflicting interests of all of the constituents of a metropolitan area.

In Asia, the emerging industrial economies of the post-World War II period produced cities following many of the patterns of the West. These rapidly developing countries, however, are still preoccupied with political and economic problems and have made little progress in establishing an environmental planning function in city or metropolitan government effective enough to prevent the mistakes made earlier in Western cities. There are a few outstanding examples of planned new cities in such widely scattered places as India, Israel, and South America. There are also signs of increasing concern in Puerto Rico, India, Indonesia, and elsewhere for regional development programs. (Ed.)

Modern city government

A city cannot operate without a government of some kind. There are, indeed, no known examples of a city without government, however far back one goes in history. In some European countries cities were for centuries virtually independent political entities. Although the city-states of ancient Greece are the most famous illustration of this phenomenon, local government in such countries as England, France, Italy, Spain, and Germany is much older than national government. In the modern world, however, cities are contained within the boundaries of national states, and city government forms part of a much larger and more complex constitutional regime.

City government as a reflection of national government

City government invariably reflects the general characteristics of this national regime. When political democracy exists at the national level, as in most of the Western world and Japan today, cities enjoy a substantial degree of local autonomy and have democratic systems of government. When the regime is authoritarian, central control is likely to diminish or extinguish local self-government and to suppress democratic forms. Similarly, a country that prefers to concentrate power and responsibility in a single individual—or, conversely, in a committee—is likely to display this preference in its cities no less than in its central government.

BASIC CHARACTERISTICS OF CITY GOVERNMENT

Jurisdictions of cities. Hitherto, the jurisdiction of city governments has been limited to the built-up urban area although there are exceptions to this, as, for example, in Brazil and South Africa. A clear distinction between the city and the surrounding countryside no longer exists. The built-up central area extends without any sharp dividing line to the suburbs, then to the farther fringe composed of housing estates and villages for commuters, interspersed with small produce farms, recreational areas, industrial estates, and so forth, all of which may form a single area of interrelated activities. An army of commuters daily invades the main city, and at the close of the day they retreat to their homes in the suburbs or beyond. They and their families use the city for such purposes as recreation, trade, shopping, professional services, and higher or technical education. The city depends for its economic health on their services and their purchasing power. But commuters also have to be provided with costly daytime services such as police and fire protection, water supply, sewage, public health, highways, and public transport, although those who live outside the city limits usually contribute little or nothing to the municipal revenue.

Urban technology and the patterns of behaviour of contemporary life have made it difficult or impossible for municipalities to cope with the mounting problems of the city region, and particularly those of the metropolitan areas, unless drastic changes of structure and scope are carried out.

City services. Certain functions must be performed in every city. Law and order must be maintained; there must be some regulation of building to ensure a minimum of safety and to ensure that houses or workshops are not constructed on public land or in improper places; there must be regular methods of preventing, controlling, and extinguishing fires; and there must be regulations and executive action to protect the health of the citizens. The services now provided by city governments are different in nature and wider in scope than in the past. Generalization is impossible, but the most widespread functions today are the environmental and personal health services, including clinics and hospitals; primary, secondary, and further education; water supply, sewage, refuse collection and disposal; construction, maintenance, and lighting of streets; public housing; welfare services for the old, destitute, physically and mentally handicapped, orphans and abandoned children, unemployed and disabled workers, and other categories needing help; cemeteries and crematoriums; markets and abattoirs. The traditional services have been transformed beyond recognition.

The primary functions of law, order, safety, and health

Many cities have had museums and art galleries for a century or more. Today such institutions are often part of extensive programs for recreation and culture sponsored by the municipality. Public parks and playgrounds are not a new feature of city life, but they too have become part of the comprehensive programs of outdoor recreation organized by the municipality.

A group of public-utility services comprising the supply of gas, electricity, water, and public transport are frequently provided by the city government itself, by a public corporation closely connected with it, or by a commercial company operating under a concession granted by the municipality. In some countries, municipal enterprise in the public utility field has been supplanted by larger regional or national schemes.

A city council inevitably takes an interest in the economic well-being of the city that it governs. Every city government wishes to assist industry and promote trade, but there are great differences in the role assigned to local authorities in this respect in different countries. In the former Communist regimes of eastern Europe, nearly the whole of local trade and much local industry was directly or indirectly under the control of the city government. On the other hand, in the United States a city government can control local industry only by means of zoning regulations, restrictions imposed under public health legislation, and so forth. In any case, municipal governments can do much to assist industry and commerce by good planning and physical development, by providing for trade fairs and exhibition centres, and by designing and developing roads, public housing, schools, and other municipal services to meet the needs of employers and employees.

Promotion of industry and commerce

The attraction of tourists also has become an almost universal goal of every city that has the slightest pretension to be of interest to visitors, and here too the municipality can do much to attract tourists by providing not only publicity and information but also convenient and agreeable facilities.

TYPES OF CITY GOVERNMENT

There are today three principal types of municipal systems of government: (1) the decentralized system found in federal constitutions; (2) the decentralized system found in unitary constitutions; and (3) the supervisory system found under the "Napoleonic," or French-type, administration. A fourth type, the integrated system, was found in eastern Europe until the collapse of Communism.

Decentralized city government in federal systems. In federal constitutions, local government tends to fall within the jurisdiction of the state or provincial government rather than of the national government. This is the position in the United States, and it accounts for the great diversity of municipal organization existing in that country.

Mayor and council

United States. The mayor-and-council form is the traditional type of city government in the United States. It prevails in a majority of American cities whether large or small. The relations between the mayor and the council are by no means uniform, but in general the borough or city council, which was the dominant partner in colonial days, has lost power as the role of the mayor has expanded. Bicameral councils have disappeared.

In the weak-mayor form, the council retains a good deal of administrative power that it exercises through committees. The mayor has few administrative powers but possesses a number of legislative and judicial functions. Many of the municipal officers in such cities are directly elected. In the past the result was often a lack of organized leadership because power and responsibility were too widely diffused. The only person able to coordinate the fragmented authority of these several parts of the city government was the party boss. It has been truly remarked that the price paid for his services was high (in graft) even though his product was of low quality.

It is against this background that the rise of the strong-mayor system is to be seen—a system that now exists in most of the larger American cities and many of the smaller ones. In this type, the mayor presides over the council and usually has the right to veto its ordinary legislative acts. The veto may be absolute, or it may be a suspensory veto that can be overcome if the measure in question is again passed by the council by a specified majority. The mayor usually prepares the budget for submission to the council; convenes special sessions of the council to consider particular questions; appoints and dismisses heads of departments and can give them instructions or directions; appoints the chairmen and members of boards or commissions; and decides or participates in the appointment of other city employees, such as policemen, firemen, and clerks, though patronage of this kind may be restricted by a civil service commission.

In the commission form the council is replaced by a small body of elected commissioners who decide general policies of municipal administration in addition to performing the usual functions of a council. Each of the commissioners also serves as head of one or more departments. The commission may also appoint various boards and committees to work with it in such spheres as health, libraries, and recreation. A member of the commission is chosen to be mayor either by the citizens or by his fellow commissioners. He is not the chief executive but only *primus inter pares* ("first among equals"). He seldom has a veto power and is distinguished from the other commissioners only on ceremonial occasions.

The commission pattern of city government has never made great inroads on the mayor-and-council form. It exists in fewer than 10 percent of American municipalities at the present time and is now on the decline. Its lack of success is due to the divided authority among the elected commissioners and its inability to concentrate responsibility in a single officer.

City manager

A more serious challenge to the traditional form of city government came from the city-manager system. The most recently developed and the most rapidly spreading, it is derived from the method of organizing business corporations that was in favour in the first quarter of the 20th century; a general manager was entrusted with operating activities by a board of directors to whom he was responsible. When the concept was applied to city government, there emerged a small council numbering from three to nine members, all elected at large. The council passes ordinances, adopts the budget, decides rates of taxation, and engages the manager. The mayor (if there is one) has a role that is chiefly ceremonial. The city manager is the real chief executive; his position is generally set out in the city charter, which states that the council shall not interfere with his administrative functions. He has a duty to provide the council with whatever information they need to determine matters of policy.

Independent boards and commissions

In addition to the municipal government, there are in most American cities a considerable number of ad hoc boards and commissions possessing varying degrees of independence. The school board is invariably separate from the rest of the city administration, and there are usually many other independent boards. Some of them can appoint and dismiss their own staff. The mayor may have the power to appoint the chairmen and members, but thereafter his power to direct or influence them may become slight or even negligible. A widespread characteristic of all forms of American city government is the fragmentation of authority caused by such devices.

State governments in the United States exercise many different kinds of supervision and control over the cities within their jurisdiction. The structure of local government is determined by state law, and every municipality owes its corporate status and machinery of self-government to the state.

Germany. The primary unit of local government in the Federal Republic of Germany is the commune or municipality (*Gemeinde*). It may be either rural (*Landgemeinde*) or urban (*Stadt*). Above the municipality is the *Kreis,* which corresponds to a district or county containing villages, hamlets, and small towns; it is an upper tier of local self-government that exercises supervisory powers and also provides services. There are nearly 400 *Kreise.* Some 120 towns with more than 50,000 inhabitants, however, are independent of this *Kreis* (*kreisfreie Städte,* or *Kreis*-free towns). Above the *Kreis* is the province or administrative district (*Regierungsbezirk*) of the state (*Land*), though the *Regierungsbezirk* does not exist in the smaller states such as the Saarland, Schleswig-Holstein, Mecklenburg-Vorpommern, Brandenburg, and Thyringia. The three great cities of Bremen, Hamburg, and Berlin rank as states as well as municipalities; they are subdivided into circuits (*Bezirke*) with their own elected assemblies.

The legal status of communes is based on municipal constitution laws of their respective states (*Länder*) and on the state constitutions. The federal constitution guarantees the communes the right to regulate on their own all the affairs of the local community within the legal limits and requires that the representative organs of the municipalities shall be elected by universal, direct, free, equal, and secret ballot. A constitutional amendment of 1993 allows residents from EC countries to vote or to be elected. The elected council is the supreme organ in the municipality, and chief executives must be chosen by either the citizens or the council.

The structure of local government varies among the different states, related to historical traditions and post-World War II allied influence. In Bavaria and Baden-Württemberg, the burgomaster (*Bürgermeister*) and deputy burgomasters, who form the executive organ, are directly elected by the citizens. In North Rhine–Westphalia and Lower Saxony, the burgomaster retains only political functions, his former administrative functions having been transferred to a city director (*Stadtdirektor*) or chief executive officer. The *Bürgermeisterverfassung* prevails in Rhineland-Palatinate, in the Saarland, and in a number of villages in Schleswig-Holstein. It entails a functional distinction between the respective powers of the council and the mayor. The *Magistratsverfassung* obtains in Hesse, in the larger towns of Rhineland-Palatinate, in Schleswig-Holstein, and in Bremerhaven. The council elects the burgomaster to serve as its chairman and as the head of the administration. Whatever the form of the executive organ, it must prepare and carry out the resolutions, policies, and administrative decisions of the council. Only in urgent matters or emergencies can the executive decide in

place of the council, although the burgomaster can veto the council's decisions when it is in violation of the law.

Decentralized city government in unitary systems. *Great Britain.* The Local Government Act of 1972 created a two-tier system of counties and districts. Both counties and districts have independent, locally elected councils that perform separate functions: county authorities are generally responsible for large-scale services, while district authorities are generally responsible for more local ones. In certain heavily populated areas, counties and districts are designated metropolitan counties and districts, and provision of certain large-scale services falls upon these more powerful metropolitan district authorities.

In Britain, as elsewhere, central control has grown during the 20th century. Each department of the national government uses its own methods, but typical among them are the approval (or rejection) of schemes submitted by local authorities for town planning, education, and highways; approval of the appointment or qualifications of chief officers; and approval of slum clearance schemes and purchases of land. They also hear appeals by citizens dissatisfied with certain decisions of local authorities, and they inspect the police forces and the schools administered by local authorities. The overriding feature of central–local relations is the fact that local authorities have become increasingly dependent on central grants for their revenue. Their only source of tax revenue consists of a council tax paid by each household. The result is that central grants are larger than income from local taxes. Unless local authorities are given additional sources of fiscal revenue, they are unlikely to achieve a position of greater independence—despite strong movements for the reform of local controls and for a reduction in central control.

Japan. After World War II, a radical reform of local government took place directed toward the creation of political democracy in Japan. The new constitution provided that local authorities should be organized and operated in accordance with the principle of local autonomy, that both the chief executives and the local assemblies should be directly elected by popular vote, and that local authorities should have the right to manage their property and affairs and to make their own regulations within the law. A Local Autonomy Law passed in 1947 prescribed in detail the organization and functions of local government. Legislation followed on finance and the public service.

Local government structure

The municipalities consist of cities (*shi*), towns (*machi*), and villages (*mura*). All have the same structure and legal status but differ in powers. A city must have a population of not less than 50,000 (formerly 30,000), of which at least 60 percent must engage in commerce and industry; and it must possess civic halls, a sewage system, libraries, and other public amenities. In 1953 a compulsory amalgamation of local government units reduced the number of towns and villages from 9,610 to 2,915, while the number of cities was increased to 556. These figures have not changed significantly since.

The separation of powers is applied in municipalities of all types. The mayor is directly elected by the voters and so too is the assembly, of which he is not a member; the only exceptions are the special wards in which the mayors are appointed by the ward council with the concurrence of the metropolitan governor. The assembly passes the budget, enacts bylaws, approves the accounts, decides the local taxes, disposes of property, and can demand reports or carry out investigations. The mayor controls the entire administration, except certain functions that have been entrusted to separate administrative boards. These include education boards, election administrative commissions to manage both national and local elections, audit and inspection commissions, civil service commissions, and police boards.

The mayor has the right to convene the council and to place bylaws before it. He is the ceremonial head of the city as well as its chief executive. He is also entrusted with certain duties on behalf of the central government, such as the maintenance of national roads and the census.

The control over the cities exercised by the central government is considerable. The Ministry of Autonomy is the department mainly concerned with local government, but the ministries of Finance, Education, Construction, and Transport exercise varying degrees of control over local authorities. One of the unresolved problems in Japan is the reluctance of central departments to coordinate their activities, and this often leads to serious inconsistencies and conflicts of policy.

The Napoleonic supervisory system. *France.* Until the administrative reforms of 1982, the system of local government in France was derived mainly from the French Revolution and the Napoleonic era, when the basic organization was a highly centralized administrative state in which the communes were local units of the central government. Historically this French pattern has had far-reaching influence in Europe, Africa, and Asia.

The mayor and the prefect

The French system had two tiers of authorities. In each of the communes (which comprise municipal units of all sizes, from tiny villages to large cities), there was an elected council and a mayor (*maire*), appointed by the councillors from among their own members. In each of the regional *départements* into which France is divided, there was a prefect (*préfet*) who was appointed by and responsible to the central government and who was assisted by an elected departmental council. The separation of powers was applied at both levels, and the mayor and the prefect were executive officers, whereas the councils were deliberative and legislative bodies.

The mayor was the responsible head of the municipality. He represented the local community. He presided at council meetings and carried out its decisions. He prepared the budget and submitted it to the council for its consideration. He initiated proposals for new measures or policies and approved all expenditures. In the large towns, the mayor had the help of several assistant mayors; he could delegate particular tasks to one or more of them, and he also could delegate functions to a councillor. In the larger municipalities, the mayor appointed a secretary-general who was answerable to him for the day-to-day administration, thus leaving the mayor free to devote himself to political leadership and policy making. Mayors were not infrequently among the leading national figures in French politics.

A city government was legally authorized to deal with all matters of local interest, but the extent to which it did so depended on the attitude of the council and its mayor, the resources at its disposal, and the degree of control exercised by higher authority. The prefect was the supervisory agent who possessed the authority of all the national ministries, including even those that had their own specialists working in the field. When the mayor was carrying out his duties as an agent of the state, the prefect was his hierarchical superior and could amend or set aside his decisions.

Administration at the departmental level was altered dramatically under a law passed on March 2, 1982. Decentralization policies were implemented that transferred administrative and financial powers from the appointed departmental prefects to the presidents of the locally elected departmental councils. While the departmental councils are still deliberative and legislative bodies, the presidents of the councils are now the chief executives of the *départements,* responsible for, among other things, budgetary matters and provision of services. The prefects were renamed Commissioners of the Republic and now act as representatives of the central government, overseeing the local administrative bodies and maintaining public law and order. Mayors, who are representatives of the communes and also agents of the central government, and elected councils are still the governing bodies of the communes.

More than 80 percent of the communes have populations of less than 1,000. Because units of this size cannot hope to provide the services demanded by advanced nations today, they are permitted under French law to form joint associations for common tasks, or to merge and constitute a new municipality, or to establish a *syndicat,* or corporate body, with its own budget to carry out particular functions. Although these devices have been used in cities of medium size, they have not solved the problems of the metropolitan areas. Under a law enacted in 1966,

metropolitan authorities must be established in the great urban concentrations of Lyon, Lille-Roubaix Tourcoing, Bordeaux, and Strasbourg; similar action is permitted in any other concentrated area of 50,000 or more inhabitants. Under this law, each constituent municipality continues to be responsible for administering and developing a wide range of services concerning its own area; but the metropolitan authority undertakes a number of functions of interest to the metropolis as a whole. These relate to such matters as town planning and the public services involving roads, water, sanitation, housing, industrial estates, transport, secondary schools, and the like. Also included are public investments for assisting the arts, sports, hospitals, and other social and educational facilities. The governing body of the metropolitan authority is a council of between 50 and 90 members, who are representatives of the local authorities.

Latin America. The tendency in Latin-American countries is to adopt the basic principles of the supervisory system. This involves appointing central government officers of the prefectoral type who exercise control over local authorities.

Despite this general trend, there are large differences in the degree of local autonomy existing in the various countries of Latin America. In Argentina, for example, under a succession of military governments, the former elected city councils were supplanted by advisory committees appointed from above. Democratic rule was returned to the country in 1983, however, when general elections were held, and a civilian government assumed power.

Ecuador

In Ecuador the municipalities have elected councils and indirectly elected mayors who undertake local government functions. They are supervised by the centrally appointed "political chief" of the municipality (*jefe político*); his immediate superior is the provincial governor, who is appointed by the president of the republic. The *jefe político* supervises the city council and reports any illegal or irregular acts to the provincial governor; he also performs a number of state functions in the municipality. The provincial governor is charged with maintaining public order and upholding the law and constitution and is also responsible for developing the education, health, welfare, and cultural services and the public works projects.

Chile generally had elected municipal councils that appointed their own mayors, but in the large cities of Santiago, Valparaíso, Viña del Mar, and Concepción the mayors were appointed and removable by the president. At each level of administration—provincial, departmental, municipal, and district—there was a representative of the president assisted by a small elected council. This followed the essential principle of the French system. During the military government that was in power from 1973 to 1989, officials appointed by the president were in charge of administration at the various levels.

Even more subordinate to the central government are the cities in countries where the mayor is appointed by either the president or the prefect on his behalf. This occurs in such countries as Bolivia and Colombia. The municipalities have elected councils, but their functions are mainly advisory. A high degree of local autonomy exists in Mexico, where both mayors and councils are elected.

The integrated system. The now-defunct Soviet Union, which provided the model for the integrated system of city government, was from its beginning based on local "soviets" (elected councils). These were set up by the Communist Party in every province, district, city, town, or village throughout the land. The soviets were responsible not only for managing the affairs of their own areas but also for electing the soviet of the next higher level of government. Thus, the entire hierarchy of councils except those at the lowest level was based on indirect election. For this reason, the Soviet Union was originally described as a state of soviets. When direct election was introduced at all levels in 1936 this ceased to be a correct description, but the local soviets remained organs of local government. The regime, however, retained a feature of great importance known as "democratic centralism." This means that each local authority was responsible to and had to carry out the directions of the corresponding organ at the next higher level of government. Although some policies could originate locally, they had to be submitted to the next higher soviet for approval or, if of sufficient importance, to even higher soviets. This hierarchical and integrated structure explains why every soviet was considered a local organ of the state.

A city soviet elected an executive committee (*ispolkom*), which in turn appointed a presidium, the principal executive organ. The presidium formulated operational and financial policies and directed the conduct of the city's services, whereas the full executive committee confined itself mainly to confirming the actions of the presidium. The executive committee was also responsible for preparing the agenda for the soviet, seeing that its decisions were carried out, ensuring that directions from above were obeyed, and giving advice or help to deputies and their committees. The president was the most important public figure in the municipality; he supervised personnel policy, convened meetings of the executive committee, saw that complaints and petitions from citizens came to the executive committee, allocated functions to the administrative departments, and generally supervised the work of the city government. He was likely to be held personally responsible if things went wrong or if plans were not fulfilled.

The city soviet wielded comparatively little power. Its short sessions, large membership, and crowded agenda precluded detailed discussion of problems. The deputies nevertheless formed a vital link between the citizens and the city government; and, moreover, the city soviets did have standing commissions composed of deputies and interested citizens called activists who were prepared to take an interest in a particular service such as housing or public health. In a large city, there might be as many as 15 of these commissions inspecting and reporting grievances or defects to the soviet, including alleged improper or criminal actions on the part of officials. About 2,500,000 activists were engaged in this work of the commissions. This attempt to achieve mass participation in the conduct of local government was a special feature of the soviet system. It existed side by side with a high degree of central control.

Functions of soviet city governments

A city government in the Soviet Union had in theory an almost unlimited jurisdiction. It administered the services for which municipal authorities were responsible in most developed countries, but in addition it was engaged in retail distribution, local industry of many kinds, public utilities, and many other kinds of municipal enterprises. It controlled the entire construction industry and employed all of the architects. A city soviet even controlled many aspects of industrial enterprises that were not directly subordinate to it. This extensive range of functions was liable to restriction, expansion, or direction by the soviet organs at the next higher level of government or by the Communist Party apparatus. With increasing knowledge, professional skill, and experience, however, the governments of the larger cities had been accorded a correspondingly greater degree of discretion in dealing with municipal affairs.

Cities with a population exceeding 100,000 might have a lower tier of wards or *rayon* soviets. They were, in most respects, replicas of the main city government except that their executive committees did not appoint presidia; they also had fewer administrative departments. A *rayon* soviet shared many functions with the main city government. It could run the local shops, schools, clinics, and even hospitals. It had its own planning organ and its own budget, but its plans had to be approved by the city government, and the expenditure and revenues of the *rayon* were embodied in the budget of the main city.

Metropolitan control

The problem of reorganizing local government in metropolitan areas to adjust it to changes in the distribution of population, the location of employment, and patterns of commuting had been solved more easily in the Soviet Union than in Western countries. One reason was that the large city government exercised a much greater degree of control over the surrounding area. Another advantage was the ease with which changes in the arrangement or boundaries of areas and authorities were carried out; such matters, under the direction of republican ministries, were effected with little difficulty or opposition.

Distribution of the various systems. The types of city government described in this article form the basis of nearly every system of local self-government in the civilized world. The British system was transplanted to the United States, Canada, Australia, New Zealand, Ireland, and South Africa, although in each of those countries significant divergences appeared. The most important was the emergence in the United States of a strong, directly elected mayor as the chief executive responsible for the administration of the city, subject to certain overriding controls by the city council. The British system also was established in the former British colonies in Africa and Asia under the tutelage of British-appointed officers resembling prefects. (In the largest Indian cities, such as Calcutta and Bombay, however, the state government appoints a municipal commissioner who controls the administration.) The system of directly elected mayor and council has been transplanted from the United States to parts of Germany, Japan, the Philippines, and one or two Latin-American states. The French system was established in all of the former French colonies, but it has also been widely imitated in Latin America and elsewhere.

The principal problems confronting city governments are broadly similar irrespective of the constitutional type. They concern the planning and development of large cities, particularly those classed as metropolitan areas; the continual erosion of local autonomy by the increase of central governmental control; the municipal dependence on grants and subsidies from the central government; and the immense difficulty of providing adequate traffic and transport facilities, housing, education, and welfare services at an acceptable standard. Finally, the deterioration of the environment has become a matter of serious concern that is likely to persist for many years. (W.A.R./Ed.)

PARK, *Human Communities* (1952), a pioneer sociological analysis of urbanization; HENRI PIRENNE, *Medieval Cities* (1925), a historical treatment of the emergence of cities from the collapse of the Roman Empire through the Middle Ages; GIDEON SJOBERG, *The Pre-Industrial City* (1960), a comparative study of preindustrial cities with special focus on common characteristics; R.E. TURNER, *The Great Cultural Traditions*, vol. 1, *The Ancient Cities* (1941), a historical synthesis of the origin of cities from Neolithic times to Greek civilization; A.F. WEBER, *The Growth of Cities in the Nineteenth Century* (1899, reprinted 1963), history and statistics of urban growth in the 19th century in the United States, Europe, and selected Asian, African, and Latin-American countries. CARL ABBOTT, *The New Urban America: Growth and Politics in Sunbelt Cities* (1981), describes the post-World War II growth of cities in the southern United States.

For historical background on urban planning, see ERWIN A. GUTKIND, *International History of City Development*, 5 vol. (1964–70). For modern practice, see W.I. GOODMAN and ERIC C. FREUND (eds.), *Principles and Practice of Urban Planning*, 4th ed. (1968); MICHAEL P. BROOKS, *Social Planning and City Planning* (1970); KEVIN LYNCH, *Site Planning*, 2nd ed. (1971); FREDERICK H. BAIR, JR., *Planning Cities: Selected Writings on Principles and Practice* (1970); and CHARLES ABRAMS, *Man's Struggle for Shelter in an Urbanizing World* (1964).

The most useful general description of city government in many countries is S. HUMES and E.M. MARTIN, *The Structure of Local Government: A Comparative Survey of 81 Countries* (1969). A much more detailed study of a selected group of large cities may be found in W.A. ROBSON and D.E. REGAN (eds.), *Great Cities of the World: Their Government, Politics and Planning*, 3rd rev. ed. (1971). Local government in Europe is considered in W. HAUS and A. KREBSBACH, *Gemeindeordnungen in Europa* (1967), a reference volume in English, French, German, and Italian; and W. ANDERSON (ed.), *Local Government in Europe* (1939). For the United States, see H.F. ALDERFER, *American Local Government and Administration* (1956); H. ZINK, *Government of Cities in the United States* (1939); and E.C. BANFIELD and J.Q. WILSON, *City Politics* (1963). The history of English city government may be studied in SIDNEY and BEATRICE WEBB, *The Manor and the Borough*, 2 vol. (1908, reprinted 1963); J. REDLICH and F.W. HIRST, *The History of Local Government in England* (1903, reprinted 1958); and J.H. THOMAS, *Town Government in the Sixteenth Century* (1933). Modern history is covered in H.J. LASKI, W.I. JENNINGS, and W.A. ROBSON (eds.), *A Century of Municipal Progress 1835–1935* (1935); J.H. WARREN, *The English Local Government System* (1968); G. RHODES, *The Government of London: The Struggle for Reform* (1970); and W.A. ROBSON, *Local Government in Crisis*, 2nd ed. (1968). The best historical work dealing with Germany is W.H. DAWSON, *Municipal Life and Government in Germany* (1914). R.H. WELLS, *German Cities* (1932), carries the story up to the collapse of democracy in face of the Nazi regime. For a recent statement, see KEVIN LYNCH, *A Theory of Good City Form* (1981).

On French city government, see B. CHAPMAN, *Introduction to French Local Government* (1953), and *Prefects and Provincial France* (1955); and F. RIDLEY and J. BLONDEL, *Public Administration in France* (1964). For Italy the only relevant work is R.C. FRIED, *The Italian Prefects* (1963). On Latin America there is very little of value, but some information may be found in JACQUES LAMBERT, *Amérique Latine, structures sociales et institutions politiques* (1963; Eng. trans., *Latin America: Social Structure and Political Institutions*, 1967). Local government in the former Soviet Union is discussed in L.G. CHURCHWARD, *Contemporary Soviet Government* (1968); L. SCHAPIRO, *The Government and Politics of the Soviet Union*, 2nd ed. (1967); H. MCCLOSKY and J.E. TURNER, *The Soviet Dictatorship* (1960); and D.J.R. SCOTT, *Russian Political Institutions*, 4th ed. (1969). The special problems of metropolitan areas are analyzed in R.E. DICKINSON, *City Region and Regionalism* (1947); and in the reports of the WORLD CONFERENCE OF LOCAL GOVERNMENT, *Local Government Structure and Organization: Problems of Metropolitan Areas* (1962).

Climate and Weather

From the ancient Greek origins of the word (*klíma*, "an inclination or slope"—*e.g.*, of the Sun's rays; a latitude zone of the Earth; a clime), and from its earliest usage in English, climate has been understood to mean the atmospheric conditions that prevail in a given region or zone. In the older form, "clime," it was sometimes taken to include all aspects of the environment, including the natural vegetation. The best modern definitions of climate regard it as constituting the total experience of weather and atmospheric behaviour over a number of years in a given region. Climate is not just the "average weather" (an obsolete, and always inadequate, definition). It should include not only the average values of the climatic elements, such as temperature, humidity, rainfall, and wind, that prevail at different times but also their extreme ranges, variability, and the frequency of various occurrences. Just as one year differs from another, decades and centuries are found to differ from one another by a smaller but sometimes significant amount: climate is, therefore, time-dependent, and climatic values or indices should not be quoted without specifying what years they refer to.

This article treats the factors that produce weather and climate and the complex processes that cause variations in both. Other major points of coverage include global climatic types and microclimates. The article also considers both the impact of climate on human life and the effects of human activities on the climate. Due attention is given to the scientific measurement of atmospheric conditions and weather forecasting. For details concerning the disciplines of meteorology and climatology, see EARTH SCIENCES, THE. See also the article ATMOSPHERE for further information about the properties and behaviour of the atmospheric system. Relevant data on the influence of the oceans and of atmospheric moisture on climate can be found in HYDROSPHERE, THE. (Ed.)

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 221, 222, 223, and 10/33, and the *Index*.

This article is divided into the following sections:

SOLAR RADIATION AND TEMPERATURE

Air temperatures have their origin in the absorption of radiant energy from the Sun. They are subject to many influences, including those of the atmosphere, ocean, and land, and are modified by them. As variation of solar radiation is the single most important factor affecting climate, it is considered here first.

Solar radiation

DISTRIBUTION OF RADIANT ENERGY FROM THE SUN

Nuclear fusion deep within the Sun releases a tremendous amount of energy that is slowly transferred to the solar surface, from which it is radiated into space. The planets intercept minute fractions of this energy, the amount depending on their size and distance from the Sun. A one-square-metre (11-square-foot) area perpendicular to the Sun at the top of the Earth's atmosphere, for example, receives about 1,365 watts of solar power. (This amount is comparable to the power consumption of a typical electric heater.) Because of the slight ellipticity of the Earth's orbit around the Sun, the amount of solar energy intercepted by the Earth steadily rises and falls by ±3.4 percent throughout the year, peaking on January 3 when the Earth is closest to the Sun. Although about 31 percent of this energy is not used as it is scattered back to space, the remaining amount is sufficient to power the movement of atmospheric winds and oceanic currents and to sustain nearly all biospheric activity.

Most surfaces are not perpendicular to the Sun, and the energy they receive depends on the solar elevation angle (90° for the overhead Sun). This angle changes systematically with latitude, the time of year, and the time of day. The noontime elevation angle reaches a maximum at all latitudes north of the Tropic of Cancer (23.5° N) around June 22 and a minimum around December 22 (Figure 1). South of the Tropic of Capricorn (23.5° S) the opposite holds true, and between the two tropics the maximum occurs twice a year. When the Sun has a lower elevation angle, the solar energy is less intense because it is spread out over a larger area (Figure 2). Variation of solar elevation is thus one of the main factors that accounts for the dependence of climatic regime on latitude. The other main factor is the length of day. For latitudes poleward of 66.5°, the length ranges from zero (winter solstice) to 24 hours (summer solstice), whereas the Equator has a constant 12-hour day throughout the year. The seasonal range of temperature consequently decreases from high latitudes to the tropics, where it becomes less than the diurnal range of temperature.

Variation of solar elevation and length of day

EFFECTS OF THE ATMOSPHERE

Of the radiant energy reaching the top of the atmosphere, 46 percent is absorbed by the Earth's surface on average, but this value varies significantly from place to place, depending on cloudiness, surface type, and elevation. If there is persistent cloud cover, as exists in some equatorial regions, much of the incident solar radiation is scattered back to space and very little is absorbed by the Earth's surface. Water surfaces have low reflectivity (4–10 percent), except for low solar elevations, and are the most efficient absorbers. Snow surfaces, on the other hand, have high reflectivity (40–80 percent) and so are the poorest absorbers. High-altitude desert regions consistently absorb higher than average amounts of solar radiation because of the reduced effect of the atmosphere above them.

Absorption of solar radiation by the atmosphere

An additional 23 percent or so of the incident solar radiation is absorbed on average in the atmosphere, especially by water vapour and clouds at lower altitudes and by ozone (O_3) in the stratosphere. Absorption of solar radiation by ozone shields the terrestrial surface from harmful ultraviolet light and warms the stratosphere, producing maximum temperatures of −15° to 10° C (5° to 50° F) at an altitude of 50 kilometres (30 miles). Most atmospheric absorption takes place at ultraviolet and infrared wavelengths, so that more than 90 percent of the visible portion of the solar spectrum, with wavelengths between 0.4 and 0.7 micrometre (0.00002 to 0.00003 inch), reaches the surface on a cloud-free day. Visible light, however, is scattered in varying degrees by cloud droplets, air molecules, and dust particles. Blue skies and red sunsets are in effect attributable to the preferential scattering of short (blue) wavelengths by air molecules and small dust particles. Cloud droplets scatter visible wavelengths impartially (hence clouds usually appear white) but very efficiently, so that the reflectivity of clouds to solar radiation is typically about 50 percent and may be as high as 80 percent for thick clouds.

The constant gain of solar energy by the Earth is systematically returned to space in the form of thermally emitted radiation in the infrared portion of the spectrum. The emitted wavelengths are mainly between five and 100 micrometres, and they interact differently with the atmosphere compared to the shorter wavelengths of solar radiation. Very little of the radiation emitted by the Earth's

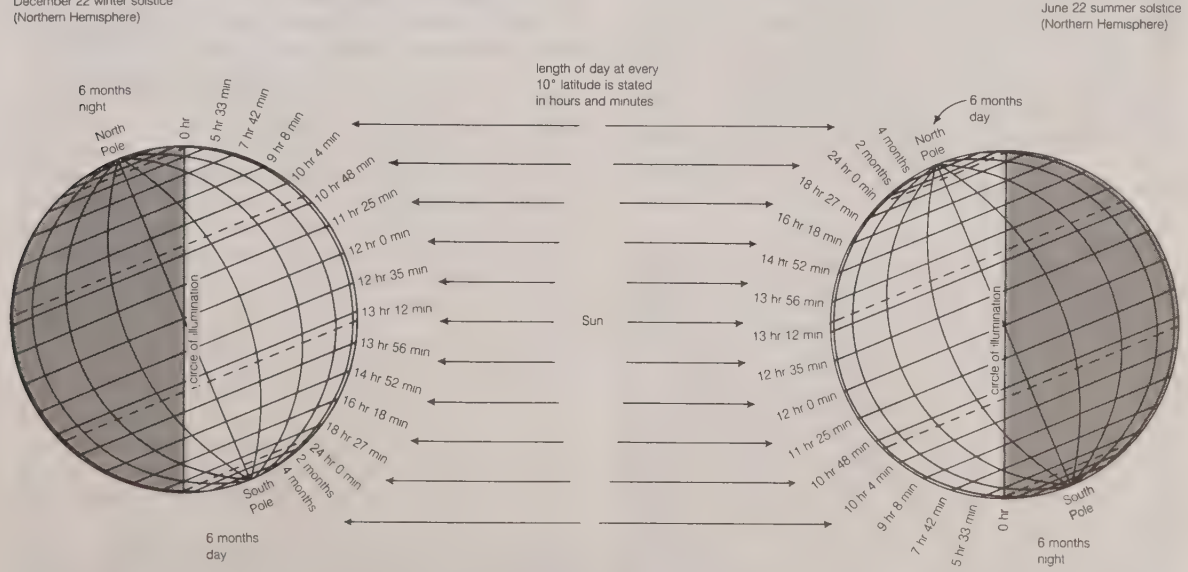

Figure 1: Vertical noontime solar rays reach 23.5° S and 23.5° N on December 22 and June 22, respectively. The circle of illumination then cuts all parallels, except the Equator, unequally, so that days and nights are unequal in length except at a latitude of 0°.

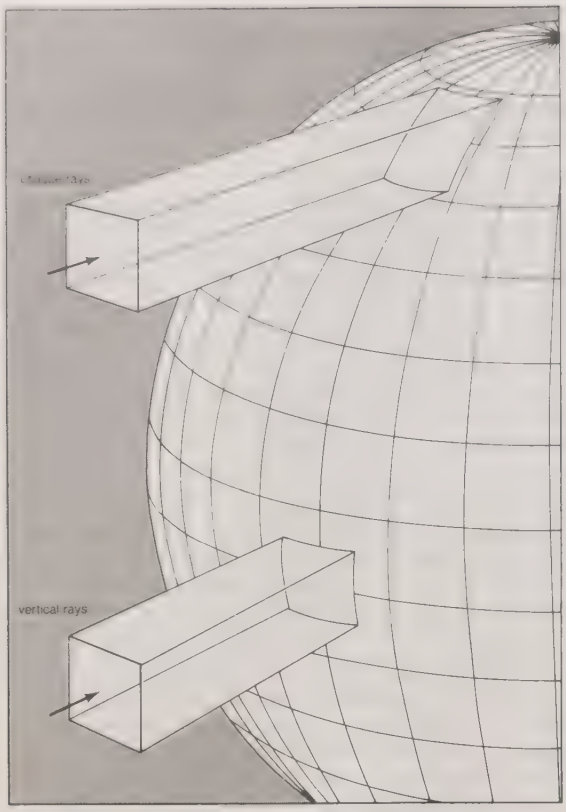

Figure 2: Less energy is received per unit area from oblique solar rays than from vertical ones.

From G T Trewartha and L H Horn, *An Introduction to Climate* (1980), McGraw-Hill Book Company, reproduced with permission of the publisher

surface passes directly through the atmosphere. Most of it is absorbed by clouds, carbon dioxide, and water vapour and is then reemitted in all directions. The atmosphere thus acts as a radiative blanket over the Earth's surface, hindering the loss of heat to space. The blanketing effect is greatest in the presence of low clouds and weakest for clear, cold skies that contain little water vapour. Without this effect, the mean surface temperature of 15° C would be some 30 degrees colder. Conversely, as atmospheric concentrations of carbon dioxide, methane, chlorofluorocarbons, and other absorbing gases continue to increase, in large part due to human activities, surface temperatures should rise because of the capacity of such gases to trap infrared radiation. The exact amount of this temperature increase, however, remains uncertain because of unpredictable changes in other atmospheric components, especially cloud cover. An extreme example of such an effect (commonly dubbed the greenhouse effect) is that produced by the dense atmosphere of the planet Venus, which results in surface temperatures of about 475° C. This condition exists in spite of the fact that the high reflectivity of the Venusian clouds causes the planet to absorb less solar radiation than the Earth.

The so-called greenhouse effect

AVERAGE RADIATION BUDGETS

The difference between the solar radiation absorbed and the thermal radiation emitted to space determines the radiation budget of the Earth. Since there is no appreciable long-term trend in planetary temperature, it may be concluded that this budget is essentially zero on a global, long-term average. Latitudinally, it has been found that much more solar radiation is absorbed at low latitudes than at high latitudes. On the other hand, thermal emission does not show nearly as strong a dependence on latitude, so that the planetary radiation budget decreases systematically from the Equator to the poles. It changes from being positive to negative at a latitude of about 40° (Figure 3). The atmosphere and oceans, through their general circulation, act as vast heat engines, compensating for this imbalance by providing non-radiative mechanisms for the transfer of heat from the Equator to the poles.

The atmosphere and oceans as heat engines

While the Earth's surface absorbs a significant amount of thermal radiation due to the blanketing effect of the atmosphere, it loses even more through its own emission, and thus experiences a net loss of long-wave radiation. This loss is only about 14 percent of the amount emitted by the surface and is less than the average gain of absorbed solar energy. Consequently, the surface has on average a positive radiation budget.

By contrast, the atmosphere emits thermal radiation both to space and to the surface, yet it receives long-wave radiation back from only the latter. This net loss of thermal energy cannot be compensated for by the modest gain of absorbed solar energy within the atmosphere. The atmosphere thus has a negative radiation budget, equal in magnitude to the positive radiation budget of the surface but opposite in sign. Non-radiative heat transfer again compensates for the imbalance, this time largely by vertical atmospheric motions involving the evaporation and condensation of water.

SURFACE-ENERGY BUDGETS

The rate of temperature change in any region is directly proportional to the region's energy budget and inversely proportional to its heat capacity. While the radiation budget may dominate the average energy budget of many surfaces, non-radiative energy transfer and storage also are generally important when local changes are considered.

Significance of non-radiative energy transfer

Foremost among the cooling effects is the energy required to evaporate surface moisture, which produces atmospheric water vapour. Most of the latent heat contained in water vapour is subsequently released to the atmosphere during the formation of precipitating clouds, although a minor amount may be returned directly to the surface during dew or frost deposition. Evaporation increases with rising surface temperature, decreasing relative humidity, and increasing surface wind speed. Transpiration by plants also increases evaporation rates, which explains why the temperature in an irrigated field is usually lower than that over a nearby dry road surface.

Another important non-radiative mechanism is the exchange of heat that occurs when the temperature of the air is different from that of the surface. Depending on whether the surface is warmer or cooler than the air next to it, heat is transferred to or from the atmosphere by turbulent air motion (more loosely, by convection). This effect also increases with increasing temperature difference and with increasing surface wind speed. Direct heat transfer may be an important cooling mechanism that limits the maximum temperature of hot, dry surfaces. Alternatively, it may be an important warming mechanism that limits the minimum temperature of cold surfaces. Such warming is sensitive to wind speed, so that calm conditions promote lower minimum temperatures.

In a similar category, whenever a temperature difference occurs between the surface and the medium beneath the

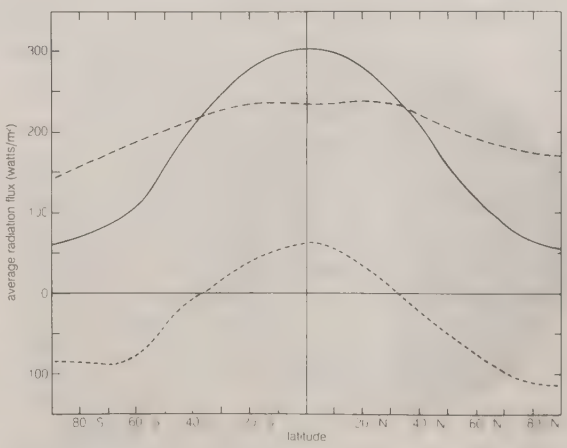

Figure 3: *Dependence of each component of the average planetary radiation budget on latitude.*
The solid curve represents absorbed solar radiation; the dashed curve, the net emission of long-wave radiation; and the dotted curve, the net radiation.

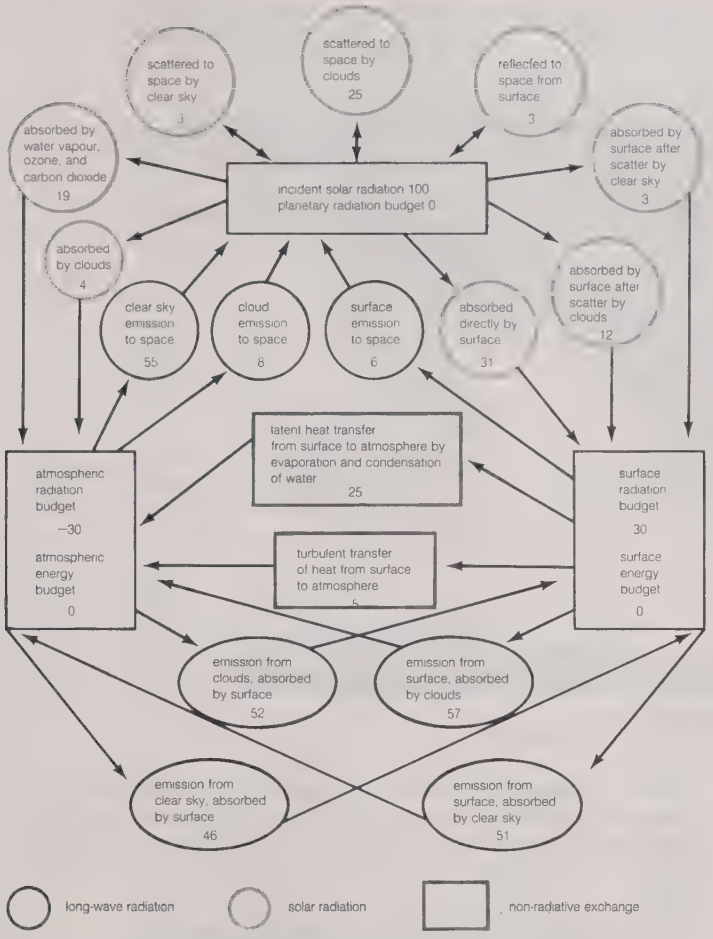

Figure 4: Average exchange of energy between the surface, atmosphere, and space, as percentages of incident solar radiation (1 unit = 3.4 watts per square metre).

surface, there is a transfer of heat to or from the medium. In the case of land surfaces, heat is transferred by conduction. In the case of water surfaces, the transfer is by convection and may consequently be affected by the horizontal transport of heat within large bodies of water.

Heat transfer by conduction and convection

Average values of the different terms in the energy budgets of the atmosphere and surface are given in Figure 4. The individual terms may be adjusted to suit local conditions and may be used as an aid to understanding the various temperature characteristics discussed in the next section. (Ro.D.)

Temperature

GLOBAL VARIATION OF MEAN TEMPERATURE

Figures 5 and 6 show the global variation of average surface air temperatures for January and July. These temperatures have been reduced to their corresponding sea-level values to remove the immediate effects of altitude. The values range from above 35° C in North Africa to below −50° C in Antarctica and show the major influences of latitude, continentality, ocean currents, and prevailing winds.

The effect of latitude is evident in the large north–south gradients in average temperature that occur at middle and high latitudes in each winter hemisphere. These gradients are due mainly to the rapid decrease of available solar radiation but also in part to the higher surface reflectivity at high latitudes associated with snow and ice and low solar elevations. A broad area of the tropical ocean, by contrast, shows little temperature variation.

Effect of continentality

Continentality is a measure of the difference between continental and marine climates and is mainly the result of the increased range of temperatures that occurs over land compared to water. This difference is a consequence of the much lower effective heat capacities of land surfaces as well as of their generally reduced evaporation rates. Heating or cooling of a land surface takes place in a thin layer, the depth of which is determined by the ability of the ground to conduct heat. The greatest temperature changes occur for dry, sandy soils because they are poor conductors with very small effective heat capacities and contain no moisture for evaporation. By far the greatest effective heat capacities are those of water surfaces, owing to the mixing of water near the surface and the penetration of solar radiation that distributes heating to depths of several metres. In addition, about 90 percent of the radiation budget of the ocean is used for evaporation. Ocean temperatures are thus slow to change.

The effect of continentality may be moderated by proximity to the ocean, depending on the direction and strength of the prevailing winds. Contrast with ocean temperatures at the edges of each continent may be further modified by the presence of a north- or south-flowing ocean current. For most latitudes, however, continentality explains much of the variation in average temperature at a fixed latitude as well as variations in the difference between January and July temperatures.

DIURNAL, SEASONAL, AND EXTREME TEMPERATURES

The diurnal range of temperature generally increases with distance from the sea and toward those places where solar radiation is strongest, in dry tropical climates and on high mountain plateaus (owing to the reduced thickness of the atmosphere to be traversed by the Sun's rays). The average difference between the day's highest and lowest temperatures in January is 3° C (in July it is 5° C) in those parts of the British Isles nearest the Atlantic. It is 4.5° C in January and 6.5° C in July on the small island of Malta. At Tashkent, Uzbekistan, it is 9° C in January and 15.5° C in July, and at Khartoum, The Sudan, the corresponding figures are 17° C and 13.5° C. At Qandahār, Afg., which lies more than 1,000 metres above sea level, it is 14° C in January, 20° C in July, and exceeds 23° C in September and October when there is less cloudiness than in July. Near the ocean at Colombo, Sri Lanka, the figures are 8° C in January and 4.5° C in July.

The seasonal variation of temperature and the magnitudes of the differences between the same month in different years and different epochs generally increase toward high latitudes and with distance from the ocean. Extreme temperatures observed in different parts of the world are listed in Table 1.

VARIATION WITH HEIGHT

There are two main levels where the atmosphere is heated—namely, at the Earth's surface and at the top of the ozone layer (about 50 kilometres up) in the stratosphere. Radiation balance shows a net gain at these levels in most cases. Prevailing temperatures tend to decrease with distance from these heating surfaces (apart from the ionosphere and outer atmospheric layers where other processes are at work). The world's average lapse rate of temperature (change with altitude) in the lower atmosphere is 0.6 to 0.7° C per 100 metres. Lower temperatures prevail with increasing height above sea level for two reasons: (1) because there is a less favourable radiation balance in the free air, and (2) because rising air—whether lifted by convection currents above a relatively warm surface or forced up over mountains—undergoes a reduction of temperature associated with its expansion as the pressure of the overlying atmosphere declines. This is the adiabatic lapse rate of temperature, which equals about 1° C per 100 metres for dry air and 0.5° C per 100 metres for saturated air in which condensation (with liberation of latent heat) is produced by adiabatic cooling. The difference between these rates of change of temperature (and therefore density) of rising air currents and the state of the surrounding air determines whether the upward currents are accelerated or retarded—*i.e.*, whether the air is unstable so that vertical convection with its characteristically attendant tall cumulus cloud and shower development is encouraged, or whether it is stable and convection is damped down.

Temperature lapse rate

For these reasons, the air temperatures observed on hills and mountains are generally lower than on low ground except in the case of extensive plateaus, which present a raised heating surface (and on still, sunny days, when even

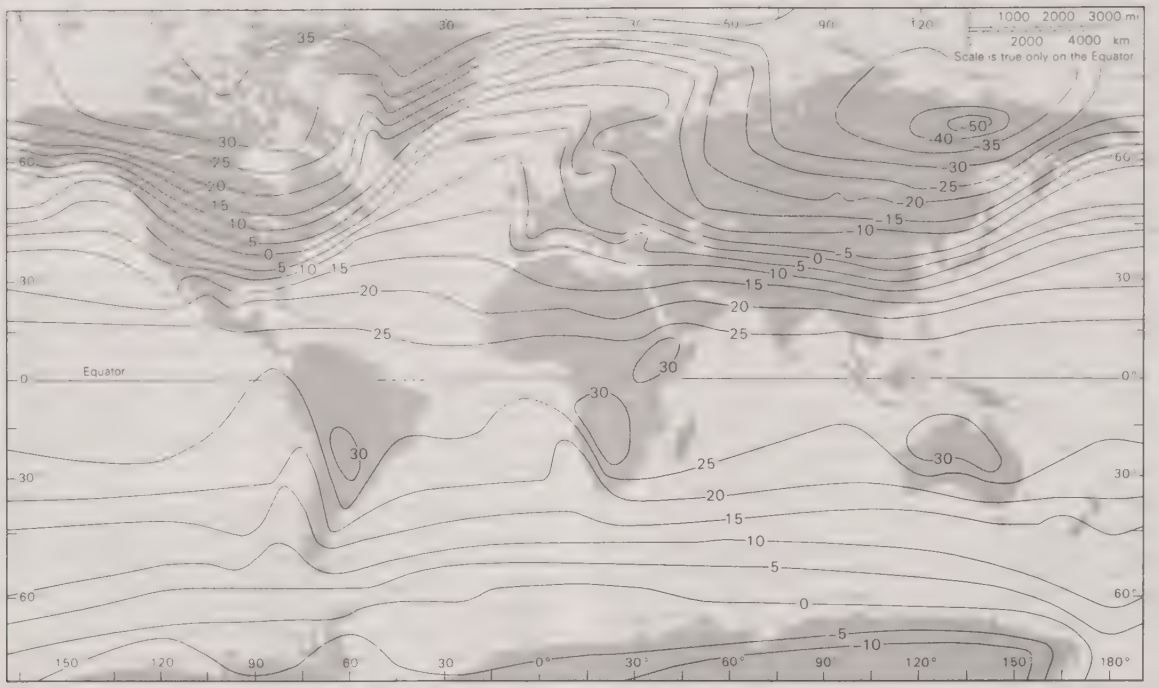

Figure 5: Average surface temperatures for January reduced to sea-level values (° C).

a mountain peak is able to warm appreciably the air that remains in contact with it).

CIRCULATION, CURRENTS, AND OCEAN–ATMOSPHERE INTERACTION

The circulation of the ocean is a key factor in air temperature distribution. Ocean currents that have a northward or southward component, such as the warm Gulf Stream in the North Atlantic or the cold Humboldt Current off South America, effectively exchange heat between low and high latitudes. In tropical latitudes the ocean accounts for a third or more of the poleward heat transport; at latitude 50° N the ocean's share is about one-seventh. In the particular sectors where the currents are located, their importance is of course much greater than these figures, which represent hemispheric averages.

Effects of currents on air temperature

A good example of the effect of a warm current is that of the Gulf Stream in January, which causes a strong east–west gradient in temperatures across the eastern edge of the North American continent (Figure 5). The relative warmth of the Gulf Stream affects air temperatures all the way across the Atlantic, and prevailing westerlies extend the warming effect deep into northern Europe. As a result, January temperatures of Tromsø, Nor. (69°40′ N), for example, average 24° C above the mean for that latitude. The Gulf Stream maintains a warming influence in July, but it is not as noticeable because of the effects of continentality.

The ocean, particularly in areas where the surface is warm, also supplies moisture to the atmosphere. This in turn contributes to the heat budget of those areas in which the water vapour is condensed into clouds, liberating latent

*Above or below sea level.

heat in the process, frequently in high latitudes and in locations remote from the ocean where the moisture was taken up.

The great ocean currents are themselves wind-driven—set in motion by the drag of the winds over vast areas of the sea surface, especially where waves increase the friction. At the limits of the warm currents, particularly where they abut directly upon a cold current, as at the left flank of the Gulf Stream in the neighbourhood of the Grand Banks off Newfoundland and at the subtropical and Antarctic convergences in the oceans of the Southern Hemisphere, the strong thermal gradients in the sea surface result in marked differences in the heating of the atmosphere on either side of the boundary. These temperature gradients tend to position and guide the strongest flow of the jet stream (see below) in the atmosphere above and thereby influence the development and steering of weather systems.

Interactions between the ocean and the atmosphere proceed in both directions. They also operate at different rates. Some interesting lag effects, which are of value in long-range weather forecasting, arise through the considerably slower circulation of the ocean. Thus, enhanced strength of the easterly trade winds over low latitudes of the Atlantic, north and south of the Equator, impels more water toward the Caribbean and Gulf of Mexico, producing a stronger flow and greater warmth in the Gulf Stream approximately six months later. Anomalies in the position of the Gulf Stream–Labrador Current boundary, which produce a greater or lesser extent of warm water near the Grand Banks, so affect the energy supply to the atmosphere and the development and steering of weather systems from that region that they are associated with rather persistent anomalies of weather pattern over the British Isles and northern Europe. Anomalies in the equatorial Pacific and in the northern limit of the Kuroshio (also called the Japan Current) seem to have effects on a similar scale. Indeed, through their influence on the latitude of the jet stream and the wavelength (that is, the spacing of cold trough and warm ridge regions) in the upper westerlies, these ocean anomalies exercise an influence over the atmospheric circulation that spreads to all parts of the hemisphere.

Sea temperature anomalies

Sea-surface temperature anomalies that recur in the equatorial Pacific at variable intervals of two to seven years can sometimes produce major climatic perturbations. Such an anomaly is known as El Niño (Spanish for "The Child"; it was so named by Peruvian fishermen who noticed its onset during the Christmas season).

El Niño event

During an El Niño event, warm surface water flows eastward from the equatorial Pacific, in at least partial response to weakening of the equatorial easterly winds, and replaces the normally cold upwelling surface water off the coast of Peru and Ecuador that is associated with the northward propagation of the cold Peru (or Humboldt) Current. The change in sea-surface temperature transforms the coastal climate from arid to wet. The event also affects atmospheric circulation in both hemispheres and is associated with changes in precipitation in regions of North America, Africa, and the western Pacific. For further information, see OCEANS: *El Niño/Southern Oscillation and climatic change.*

SHORT-TERM TEMPERATURE CHANGES

Many interesting short-term temperature fluctuations also occur, usually in connection with local weather disturbances. The rapid passage of a mid-latitude cold front, for example, can drop temperatures by 10° C in a few minutes and, if followed by a sustained movement of a cold air mass, by as much as 50° in 24 hours, with life-threatening implications for the unwary. Temperature increases of up to 40° in a few hours also are possible downwind of major mountain ranges when air that has been warmed by the release of latent heat on the windward side of a range is forced to descend rapidly on the other side (such a wind is variously called chinook, foehn, or Santa Ana). Changes of this kind, however, involve a wider range of meteorological processes than discussed in this section. For a more detailed treatment, see below *Atmospheric pressure and wind.* (H.H.L./Ro.D.)

ATMOSPHERIC HUMIDITY AND PRECIPITATION

Atmospheric humidity, which is the amount of water vapour or moisture in the air, is another leading climatic element, as is precipitation. All forms of precipitation, including drizzle, rain, snow, ice crystals, and hail, are produced as a result of the condensation of atmospheric moisture to form clouds in which some of the particles, by growth and aggregation, attain sufficient size to fall from the clouds and reach the ground.

Atmospheric humidity

At 30° C, 4 percent of the volume of the air may be occupied by water molecules, but where the air is colder than −40° C, less than one-fifth of 1 percent of the air molecules can be water. Although the water vapour content may vary from one air parcel to another, these limits can be set because vapour capacity is determined

by temperature. Temperature has profound effects upon some of the indices of humidity regardless of the presence or absence of vapour.

The connection between an effect of humidity and an index of humidity requires simultaneous introduction of effects and indices. Vapour in the air is a determinant of weather because it first absorbs the thermal radiation that leaves and cools the Earth and then emits thermal radiation that warms the planet. Calculation of absorption and emission requires an index of the mass of water in a volume of air. Vapour also affects the weather because, as indicated above, it condenses into clouds and falls as rain or other forms of precipitation. Tracing the moisture-bearing air masses requires a humidity index that changes only when water is removed or added.

HUMIDITY INDICES

Absolute humidity. Absolute humidity is the vapour concentration or density in the air. If m_v is the mass of vapour in a volume of air, then absolute humidity d_v is simply $d_v = m_v / V$, in which V is the volume and d_v is expressed in grams per cubic metre (g/m³). This index indicates how much vapour a beam of radiation must pass through. The ultimate standard in humidity measurement is made by weighing the amount of water gained by an absorber when a known volume of air passes through it, and this measures absolute humidity, which may vary from 0 g/m³ in dry air to 30 g/m³ when the vapour is saturated at 30° C. The d_v of a parcel of air changes, however, with temperature or pressure even though no water is added or removed because, as the gas equation states, the volume V increases with the absolute, or Kelvin, temperature and decreases with the pressure.

Specific humidity. The meteorologist requires an index of humidity that does not change with pressure or temperature. A property of this sort will identify an air mass when it is cooled or when it rises to lower pressures aloft without losing or gaining water vapour. Because all the gases will expand equally, the ratios of the weight of water to the weight of dry air, or the dry air plus vapour, will be conserved during such changes and will continue identifying the air mass.

The mixing ratio r is the dimensionless ratio $r = m_v/m_a$, where m_a is the mass of dry air, and the specific humidity q is another dimensionless ratio $q = m_v/(m_a + m_v)$. Because m_v is less than 3 percent of m_a at normal pressure and temperatures cooler than 30° C, r and q are practically equal. These indices are usually expressed in grams per kilogram (g/kg) because they are so small; the values range from 0 in dry air to 28 g/kg in saturated air at 30° C. Absolute and specific humidity indices have specialized uses, and so they are not familiar to most people.

Relative humidity. Relative humidity (U) is so commonly used that a statement of humidity, without a qualifying adjective, can be assumed to be relative humidity. U can be defined, then, in terms of the mixing ratio r that was introduced above. $U = 100r/r_w$, which is a dimensionless percentage. The divisor r_w is the saturation mixing ratio, or the vapour capacity. Relative humidity is, therefore, the water vapour content of the air relative to its content at saturation. Because the saturation mixing ratio is a function of pressure, and especially of temperature, the relative humidity is a combined index of the environment that reflects more than water content. In many climates the relative humidity rises to about 100 percent at dawn and falls to 50 percent by noon. A relative humidity of 50 percent may reflect many different quantities of vapour per volume of air or gram of air, and it will not likely be proportional to evaporation.

An understanding of relative humidity thus requires a knowledge of saturated vapour, which will be discussed later in the section on the relation between temperature and humidity. At this point, however, the relation between U and the absorption and retention of water from the air must be considered. Small pores retain water more strongly than large pores; thus, when a porous material is set out in the air, all pores larger than a certain size (which can be calculated from the relative humidity of the air) are dried out.

The water content of a porous material at air temperature is fairly well indicated by the relative humidity. The complexity of actual pore sizes and the viscosity of the water passing through them makes the relation between U and moisture in the porous material imperfect and slowly achieved. The great suction also strains the walls of the capillaries, and the consequent shrinkage is used to measure relative humidity.

The absorption of water by salt solutions is also related to relative humidity without much effect of temperature. The air above water saturated with sodium chloride is maintained at 75 to 76 percent relative humidity, at a temperature between 0° and 40° C.

In effect, relative humidity is a widely used environmental indicator, but U does respond drastically to changes in temperatures as well as moisture, a response caused by the effect of temperature upon the divisor r_w in U.

RELATION BETWEEN TEMPERATURE AND HUMIDITY

Tables that show the effect of temperature upon the saturation mixing ratio r_w are readily available. Humidity of the air at saturation is expressed more commonly, however, as vapour pressure. Thus, it is necessary to understand vapour pressure and in particular the gaseous nature of water vapour.

The pressure of the water vapour, which contributes to the pressure of the atmosphere, can be calculated from the absolute humidity d_v by the gas equation:

$$e = \frac{m_v}{V}\frac{RT}{M_w} = d_v\frac{RT}{M_w},$$

in which R is the gas constant, T the absolute temperature, M_w the molecular weight of water, and e water vapour pressure in millibars.

Relative humidity can be defined as the ratio of the vapour pressure of a sample of air to the saturation pressure at the existing temperature. Further, the capacity for vapour and the effect of temperature can now be presented in the usual terms of saturation vapour pressure.

Within a pool of liquid water some molecules are continually escaping from the liquid into the space above, while more and more vapour molecules return to the liquid as the concentration of vapour rises. Finally, equal numbers are escaping and returning, the vapour is then saturated, and its pressure is known as the saturation vapour pressure e_w. If the liquid and vapour are warmed, relatively more molecules escape than return, and e_w rises. There is also a saturation pressure with respect to ice. The vapour pressure curve of water has the same form as the curves for many other substances. Its location is fixed, however, by the boiling point of 100° C, where the saturation vapour pressure of water vapour is 1,013 millibars (mb), the standard pressure of the atmosphere at sea level. The decrease of the boiling point with altitude can be calculated. For example, the saturation vapour pressure at 40° C is 74 mb, standard atmospheric pressure near 18,000 metres above sea level is also 74 mb, and that is where water boils at 40° C.

The everyday response of relative humidity to temperature can be easily explained. On a summer morning the temperature might be 15° C and the relative humidity 100 percent. The vapour pressure would be 17 mb and the mixing ratio about 11 g/kg. During the day the air could warm to 25° C, while evaporation added little water. At 25° C the saturation pressure is fully 32 mb. If, however, little water has been added to the air, its vapour pressure will still be about 17 mb. Thus with no change in vapour content, the relative humidity of the air has fallen from 100 to only 53 percent, illustrating why relative humidity does not identify air masses.

Dew-point temperature. The meaning of dew-point temperature can be illustrated by a sample of air with a vapour pressure of 17 mb. If an object at 15° C is brought into the air, dew will form on the object. Hence, 15° C is the dew-point temperature of the air—*i.e.*, the temperature at which the vapour present in a sample of air would just cause saturation, or the temperature whose saturation

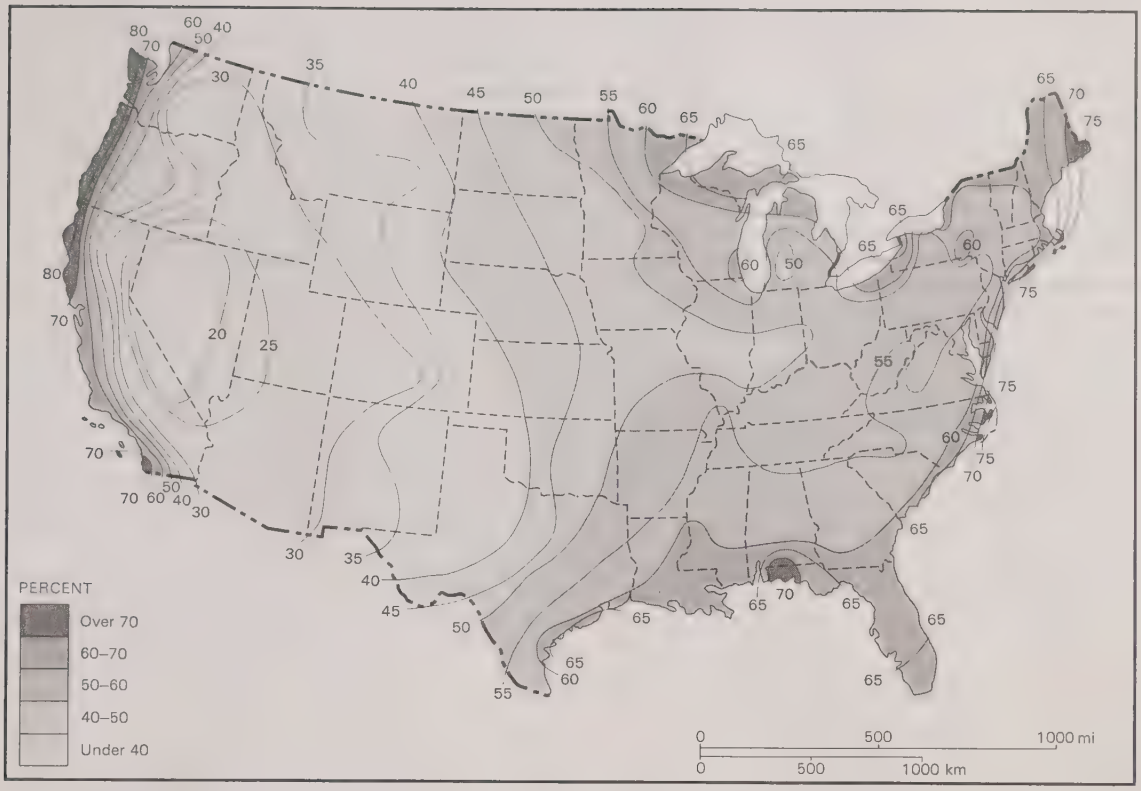

Figure 7: Average relative humidity, local noon, July.

vapour pressure equals the present vapour pressure in a sample of air, is the dew point. Below freezing, this index is called the frost point. There is a one-to-one correspondence between vapour pressure and dew point. The dew point has the virtue of being easily interpreted because it is the temperature at which a blade of grass or a pane of glass will become wet with dew from the air. Ideally, it is also the temperature of fog or cloud formation.

The clear meaning of dew point suggests a means of measuring humidity. A dew-point hygrometer was invented in 1751. In this instrument, cold water was added to water in a vessel until dew formed on the vessel, and the temperature of the vessel, the dew point, provided a direct index of humidity. The greatest use of the condensation hygrometer has been to measure humidity in the upper atmosphere where a vapour pressure of less than a thousandth millibar makes other means impractical.

The saturation deficit

Another index of humidity, the saturation deficit, can also be understood by considering air with a vapour pressure of 17 mb. At 25° C the air has (31 − 17) or 14 mb less vapour pressure than saturated vapour at the same temperature; that is, the saturation deficit is 14 mb.

The saturation deficit has the particular utility of being proportional to the evaporation capability of the air. The saturation deficit can be expressed as

$$e_w - e = e_w\left(1 - \frac{U}{100}\right),$$

and, because the saturation vapour pressure e_w rises with rising temperature, the same relative humidity will correspond to a greater saturation deficit and evaporation at warm temperatures.

HUMIDITY AND CLIMATE

The small amount of water in atmospheric vapour, relative to water on the Earth, belies its importance. Compared to one unit of water in the air, the seas contain at least 100,000 units, the great glaciers 1,500, the porous earth nearly 200, and rivers and lakes four or five units. The effectiveness of the vapour in the air is magnified, however, by its role in transferring water from sea to land by the media of clouds and precipitation and that of absorbing radiation.

The vapour in the air is the invisible conductor that carries water from sea to land, making terrestrial life possible. Fresh water is distilled from the salt seas and carried over land by the wind. Water evaporates from vegetation, and rain falls on the sea, too, but the sea is the bigger source, and rain that falls on land is most important to humans. The invisible vapour becomes visible near the surface as fog when the air cools to the dew point. The usual nocturnal cooling will produce fog patches in cool valleys. Or the vapour may move as a tropical air mass over cold land or sea, causing widespread and persistent fog, such as occurs over the Grand Banks off Newfoundland. The delivery of water by means of fog or dew is slight, however.

When air is lifted it is carried to a region of lower pressure where it will expand and cool as described by the gas equation. It may rise up a mountain slope or over the front of a cooler, denser air mass. If condensation nuclei are absent, the dew point may be exceeded by the cooling air, and the water vapour becomes supersaturated. If nuclei are present or if the temperature is very low, however, cloud droplets or ice crystals form, and the vapour is no longer in the invisible guise of atmospheric humidity.

The invisible vapour has another climatic role—namely, absorbing and emitting radiation. The temperature of the Earth and its daily variation is determined by the balance between incoming and outgoing radiation. The wavelength of the incoming radiation from the Sun is mostly shorter than three micrometres. It is scarcely absorbed by water vapour and its receipt depends largely upon cloud cover. The radiation exchanged between the atmosphere and Earth and the eventual loss to space is in the form of long waves. These long waves are strongly absorbed in the 3- to 8.5-micrometre band and in the greater than 11-micrometre range, where vapour is either partly or wholly opaque. As noted above, much of the radiation that is absorbed in the atmosphere is emitted back to Earth, and the surface receipt of long waves, primarily from water vapour and carbon dioxide in the atmosphere, is slightly more than twice the direct receipt of solar radiation at the surface. Thus the invisible vapour in the atmosphere combines with clouds and the advection (horizontal movement) of air from different regions to control the surface temperature.

The world distribution of humidity can be portrayed for different uses by different indices. To appraise the quantity

World distribution of humidity

of water carried by the entire atmosphere, the moisture in an air column above a given point on Earth is expressed as a depth of liquid water. It varies from 0.5 millimetre (0.02 inch) over the Himalayas and 2 mm over the poles in winter, to 8 mm over the Sahara, 54 mm in the Amazon region, and 64 mm over India during the wet season. During summer, the air over the United States transports 16 mm of water vapour over the Great Basin and 45 mm over Florida.

The humidity of the surface air may be mapped as vapour pressure, but a map of this variable looks much like that of temperature. Warm places are moist and cool ones are dry; even in deserts the vapour pressure is normally 13 millibars, whereas over the northern seas it is only about four millibars. Certainly the moisture in materials in two such areas will be just the opposite, and relative humidity is a more widely useful index.

The average relative humidity for July reveals the humidity provinces of the Northern Hemisphere when aridity is at a maximum. At other times the relative humidity generally will be higher. The humidities over the Southern Hemisphere in July indicate the humidities that comparable regions in the Northern Hemisphere will attain in January, just as July in the Northern Hemisphere suggests the humidities in the Southern Hemisphere during January. A contrast is provided by comparing a humid cool coast to a desert. The midday humidity on the Oregon coast, for example, falls only to 80 percent at midday, whereas in the Nevada desert it falls to 20 percent. At night the contrast is less, with averages being over 90 and about 50 percent in these two places.

Although the dramatic regular decrease of relative humidity from dawn to midday has been attributed largely to warming rather than declining vapour content, the content does vary regularly. In humid environments, daytime evaporation increases the water vapour content of the air, and the mixing ratio, which may be about 12 grams per kilogram, rises 1 or 2 g/kg in temperate places and may attain 16 g/kg in a tropical rain forest. In arid environments, however, little evaporation moistens the air and daytime turbulence tends to bring down dry air; this decreases the mixing ratio by as much as 2 g/kg.

Humidity also varies regularly with altitude. On the average, fully half the water in the atmosphere lies below 0.25 kilometre, and satellite observations over the United States in April revealed one millimetre or less of water in all the air above six kilometres. A cross section of the atmosphere along 75° W longitude shows a decrease in humidity with height and toward the poles. The mixing ratio is 16 g/kg just north of the Equator, but it decreases to 1 g/kg at 50° N latitude or eight kilometres above the Equator. The transparent air surrounding mountains in fair weather is very dry indeed.

Closer to the ground, the water vapour content also changes with height in a regular pattern. When water vapour is condensing on the Earth at night, the content is greater aloft than at the ground; during the day the content is in most cases less aloft than at the ground because of evaporation.

Evaporation and humidity

Evaporation, mostly from the sea and from vegetation, replenishes the humidity of the air. It is the change of liquid water into gaseous state, but it may be analyzed as diffusion. The rate of diffusion, or evaporation, will be proportional to the difference between the pressure of the water vapour in the free air and the vapour that is next to, and saturated by, the evaporating liquid. If the liquid and air have the same temperature, evaporation is proportional to the saturation deficit. It is also proportional to the conductivity of the medium between the evaporator and the free air. If the evaporator is open water, the conductivity will increase with ventilation. But if the evaporator is a leaf, the diffusing water must pass through the still air within the minute pores between the water within and the dry air outside. In this case, the porosity may modify the conductivity more than ventilation.

The temperature of the evaporator is rarely the same as the air temperature, however, because each gram of evaporation consumes about 600 calories and thus cools the evaporator. The availability of energy to heat the evaporator, therefore, is as important as the saturation deficit and conductivity of the air. Outdoors, some of this heat may be transferred from the surrounding air by convection, but much of it must be furnished by radiation. Evaporation is faster on sunny days than on cloudy ones not only because the sunny day may have drier air but also because the Sun warms the evaporator, thus raising the vapour pressure at the evaporator. In fact, according to the well-known Penman calculation of evaporation, this loss of water is essentially determined by the net radiation balance during the day. (P.E.W./Ed.)

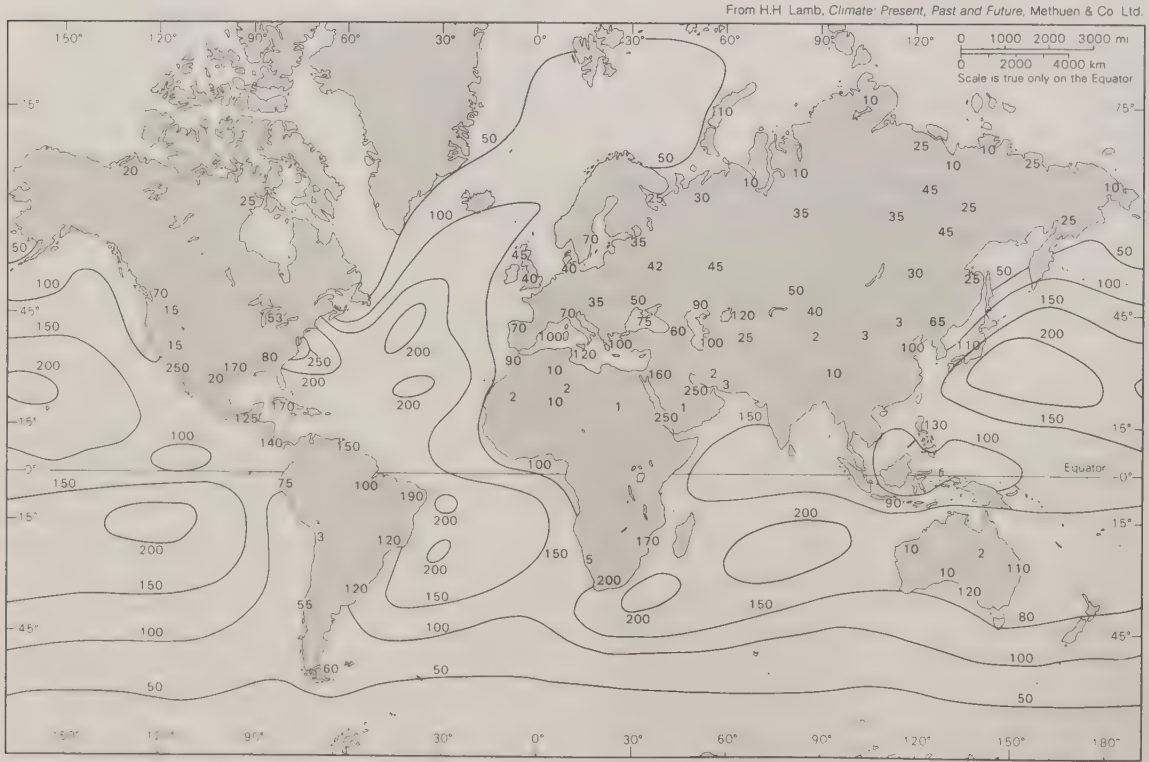

Figure 8: Average annual evaporation in centimetres.

Precipitation

Precipitation is one of the three main processes (evaporation, condensation, and precipitation) that constitute the hydrologic cycle, the continual exchange of water between the atmosphere and the surface of the Earth. Water is evaporated from ocean, land, and freshwater surfaces, is carried aloft as vapour by the air currents, condenses to form clouds, and ultimately is returned to the Earth's surface as precipitation. The average global stock of water vapour in the atmosphere is equivalent to a layer of water 2.5 centimetres (one inch) deep covering the whole Earth. Because the Earth's average annual rainfall is about 100 centimetres, the average time that the water spends in the atmosphere, between its evaporation from the surface and its return as precipitation, is about $^1/_{40}$ of a year, or about nine days. Of all the water vapour that is carried at all heights across a given region by the winds, only a small percentage is converted into precipitation and reaches the ground in that area. In deep and extensive cloud systems, the conversion is more efficient, but even in thunderclouds the quantities of rain and hail released amount to only some 10 percent of the total moisture entering the storm.

Measurement of amount and intensity

In the measurement of precipitation, it is necessary to distinguish between the amount—defined as the depth of precipitation (calculated as though it were all rain) that has fallen at a given point during a specified interval of time—and the rate or intensity—which specifies the depth of water that has fallen at a point during a particular interval of time. Persistent moderate rain, for example, might fall at an average rate of five millimetres per hour and thus produce 120 millimetres of rain in 24 hours. A thunderstorm might produce this total quantity of rain in 20 minutes, but at its peak intensity the rate of rainfall might become much greater—perhaps 120 millimetres per hour, or two millimetres per minute, for a minute or two.

The amount of precipitation falling during a fixed period is measured regularly at many thousands of places on the Earth's surface by rather simple rain gauges. Measurement of precipitation intensity requires a recording rain gauge, in which water falling into a collector of known surface area is continuously recorded on a moving chart or a magnetic tape. Investigations are being carried out on the feasibility of obtaining continuous measurements of rainfall over large catchment areas by means of radar.

Apart from the trifling contributions made by dew, frost, and rime and by desalination plants, the sole source of fresh water for sustaining rivers, lakes, and all life on Earth is provided by precipitation from clouds. Precipitation is therefore indispensable and overwhelmingly beneficial to humankind, but extremely heavy rainfall can cause great harm: soil erosion, landslides, and flooding. And hailstorm damage to crops, buildings, and livestock can prove very costly.

ORIGIN OF PRECIPITATION IN CLOUDS

Cloud formation. Clouds are formed by the lifting of damp air, which cools by expansion as it encounters the lower pressures existing at higher levels in the atmosphere. The relative humidity increases until the air becomes saturated with water vapour, then condensation occurs on any of the aerosol particles suspended in the air. A wide variety of these exist in concentrations ranging from only a few per cubic centimetre in clean maritime air to perhaps 1,000,000 per cubic centimetre (16,000,000 per cubic inch) in the highly polluted air of an industrial city. For continuous condensation leading to the formation of cloud droplets, the air must be slightly supersaturated.

Condensation nuclei

Among the highly efficient condensation nuclei are sea-salt particles and the particles produced by combustion (*e.g.*, natural forest fires and man-made fires). Many of the larger condensation nuclei over land consist of ammonium sulfate. These are produced by cloud and fog droplets absorbing sulfur dioxide and ammonia from the air. Condensation onto the nuclei continues as rapidly as water vapour is made available through cooling; droplets about 10 micrometres in diameter are produced in this manner. These droplets constitute a nonprecipitating cloud.

Cloud types. The meteorologist classifies clouds mainly by their appearance, according to an international system similar to one proposed in 1803. But because the dimensions, shape, structure, and texture of clouds are influenced by the kind of air movements that result in their formation and growth, and by the properties of the cloud particles, much of what was originally a purely visual classification can now be justified on physical grounds.

Classification of clouds

The first *International Cloud Atlas* was published in 1896. Developments in aviation during World War I stimulated interest in cloud formations and in their importance as an aid in short-range weather forecasting. This led to the publication of a more extensive atlas, the *International Atlas of Clouds and States of Sky*, in 1932 and to a revised edition in 1939. After World War II, the World Meteorological Organization published a new *International Cloud Atlas* (1956) in two volumes. It contained 224 plates, describing 10 main cloud genera (families) subdivided into 14 species based on cloud shape and structure. Nine general varieties, based on transparency and geometric arrangement, also are described. The genera, listed according to their height, are as follows:

1. High: mean heights from 5 to 13 kilometres
   a. Cirrus
   b. Cirrocumulus
   c. Cirrostratus
2. Middle: mean heights 2 to 7 kilometres
   a. Altocumulus
   b. Altostratus
   c. Nimbostratus
3. Low: mean heights 0 to 2 kilometres
   a. Stratocumulus
   b. Stratus
   c. Cumulus
   d. Cumulonimbus

Heights given are approximate averages for temperate latitudes. Clouds of each genus are generally lower in the polar regions and higher in the tropics. The definitions and descriptions of the cloud genera used in the *International Cloud Atlas* are given in the accompanying Figures 9–11, which illustrate some of their characteristic forms.

Four principal classes are recognized when clouds are classified according to the kind of air motions that produce them: (1) layer clouds formed by the widespread regular ascent of air; (2) layer clouds formed by widespread irregular stirring or turbulence; (3) cumuliform clouds formed by penetrative convection; (4) orographic clouds formed by ascent of air over hills and mountains.

Layer clouds formed by widespread regular ascent

The widespread layer clouds associated with cyclonic depressions (see below *Cyclones and anticyclones*), near fronts and other bad-weather systems, frequently are composed of several layers that may extend up to nine kilometres or more, separated by clear zones that become filled in as rain or snow develops. These clouds are formed by the slow, prolonged ascent of a deep layer of air, in which a rise of only a few centimetres per second is maintained for several hours. In the neighbourhood of fronts, vertical velocities become more pronounced and may reach about 10 centimetres per second.

Most of the high cirrus clouds visible from the ground lie on the fringes of cyclonic cloud systems, and, though due primarily to regular ascent, their pattern is often determined by local wave disturbances that finally trigger their formation after the air has been brought near its saturation point by the large-scale lifting.

On a cloudless night, the ground cools by radiating heat into space without heating the air adjacent to the ground. If the air were quite still, only a very thin layer would be chilled by contact with the ground. More usually, however, the lower layers of the air are stirred by motion over the rough ground, so that the cooling is distributed through a much greater depth. Consequently, when the air is damp or the cooling is great, a fog a few hundred metres deep may form, rather than a dew produced by condensation on the ground.

In moderate or strong winds the irregular stirring near the surface distributes the cooling upward, and the fog may lift from the surface to become a stratus cloud, which is not often more than 600 metres thick.

Radiational cooling from the upper surfaces of fogs and stratus clouds promotes an irregular convection within the

cloud layer and causes the surfaces to have a waved or humped appearance. When the cloud layer is shallow, billows and clear spaces may develop so that it is described as stratocumulus instead of stratus.

Convective clouds

Usually cumuliform clouds appearing over land are formed by the rise of discrete masses of air from near the Sun-warmed surface. These rising lumps of air, or thermals, may vary in diameter from a few tens to hundreds of metres as they ascend and mix with the cooler, drier air above them. Above the level of the cloud base the release of latent heat of condensation tends to increase the buoyancy of the rising masses, which tower upward and emerge at the top of the cloud with rounded upper surfaces.

At any moment a large cloud may contain a number of active thermals and the residues of earlier ones. A new thermal rising into a residual cloud will be partially protected from having to mix with the cool, dry environment and therefore may rise farther than its predecessor. Once a thermal emerges as a cloud turret at the summit or the flanks of the cloud, rapid evaporation of the droplets chills the cloud borders, destroys the buoyancy, and produces sinking. A cumulus thus has a characteristic pyramidal shape and, viewed from a distance, appears to have an unfolding motion, with fresh cloud masses continually emerging from the interior to form the summit and then sinking aside and evaporating.

In settled weather, cumulus clouds are well scattered and small; horizontal and vertical dimensions are only a kilometre or two. In disturbed weather they cover a large part of the sky, and individual clouds may tower as high as 10 kilometres or more, often ceasing their growth only upon reaching the stable stratosphere. These clouds produce heavy showers, hail, and thunderstorms (see below).

At the level of the cloud base the speed of the rising air masses is usually about one metre per second, but may reach five metres per second, and similar values are measured inside smaller clouds. The upcurrents in thunderclouds, however, often exceed five metres per second and may reach 30 metres per second or more.

The rather special orographic clouds are produced by the ascent of air over hills and mountains. The air stream is set into oscillation when it is forced over the hill, and the clouds form in the crests of the (almost) stationary waves. There may thus be a succession of such clouds stretching downwind of the mountain, which remain stationary relative to the ground in spite of strong winds that may be blowing through the clouds. The clouds have very smooth outlines and are called lenticular (lens-shaped) or wave clouds. Thin wave clouds may form at great heights (up to 10 kilometres, even over hills only a few hundred metres high) and occasionally are observed in the stratosphere (at 20 to 30 kilometres) over the mountains of Norway, Scotland, Iceland, and Alaska. These atmospheric wave clouds are known as nacreous, or "mother-of-pearl," clouds because of their brilliant iridescent colours.

Clouds produced by orographic disturbances

Mechanisms of precipitation release. Growing clouds are sustained by upward air currents, which may vary in strength from a few centimetres per second to several metres per second. Considerable growth of the cloud droplets (with falling speeds of only about one centimetre per second) is therefore necessary if they are to fall through the cloud, survive evaporation in the unsaturated air below, and reach the ground as drizzle or rain. The production of a few large particles from a large population of much smaller ones may be achieved in one of two ways. The first of these depends on the fact that cloud droplets are seldom of uniform size because droplets form on nuclei of various sizes and grow under slightly different conditions and for different lengths of time in different parts of the cloud. A droplet appreciably larger than average will fall faster than the smaller ones, and so will collide and fuse (coalesce) with some of those that it overtakes. Calculations show that, in a deep cloud containing strong upward air currents and high concentrations of liquid water, such a droplet will have a sufficiently long journey among its smaller neighbours to grow to raindrop size. This coalescence mechanism is responsible for the showers that fall in tropical and subtropical regions from clouds whose tops do not reach the 0° C level and therefore cannot contain ice crystals. Radar evidence also suggests that showers in temperate latitudes may sometimes be initiated by the coalescence of waterdrops, although the clouds may later reach heights at which ice crystals may form in their upper parts.

The coalescence process

The ice crystal process

The second method of releasing precipitation can operate only if the cloud top reaches elevations at which temperatures are below 0° C and the droplets in the upper cloud regions become supercooled. At temperatures below −40° C the droplets freeze automatically or spontaneously. At higher temperatures they can freeze only if they are infected with special, minute particles called ice nuclei. The origin and nature of these nuclei are not known with certainty, but the most likely source is clay-silicate particles carried up from the ground by the wind. As the temperature falls below 0° C, more and more ice nuclei become active, and ice crystals appear in increasing numbers among the supercooled droplets. Such a mixture of supercooled droplets and ice crystals is unstable, however. The cloudy air is usually only slightly supersaturated with water vapour with respect to the droplets and is strongly oversaturated with respect to ice crystals; the latter thus grow more rapidly than the droplets. After several minutes the growing crystals acquire falling speeds of tens of centimetres per second, and several of them may become joined together to form a snowflake. In falling into the warmer regions of the cloud, this flake may melt and hit ground as a raindrop.

Precipitation from layer cloud systems

The deep, extensive, multilayer cloud systems, from which precipitation of a widespread, persistent character falls, are generally formed in cyclonic depressions (lows) and near fronts. Cloud systems of this type are associated with feeble upcurrents of only a few centimetres per second that last for at least several hours. Although the structure of these great rain-cloud systems is being explored by aircraft and radar, it is not yet well understood. That such systems rarely produce rain, as distinct from drizzle, unless their tops are colder than about −12° C suggests that ice crystals are mainly responsible. This view is supported by the fact that the radar signals from these clouds usually take a characteristic form that has been clearly identified with the melting of snowflakes.

Showers, thunderstorms, and hail. Precipitation from shower clouds and thunderstorms, whether in the form of raindrops, pellets of soft hail, or true hailstones, is generally of great intensity and shorter duration than that from layer clouds and is usually composed of larger particles. The clouds are characterized by their large vertical depth, strong vertical air currents, and high concentrations of liquid water, all factors favouring the rapid growth of precipitation elements by the accretion of cloud droplets.

In a cloud composed wholly of liquid water, raindrops may grow by coalescence. For example, a droplet being carried up from the cloud base grows as it ascends by sweeping up smaller droplets. When it becomes too heavy to be supported by the upcurrents, the droplet falls, continuing to grow by the same process on its downward journey. Finally, if the cloud is sufficiently deep, the droplet will emerge from its base as a raindrop.

In a dense, vigorous cloud several kilometres deep, the drop may attain its limiting stable diameter (about six millimetres) before reaching the cloud base and thus will break up into several large fragments. Each of these may continue to grow and attain breakup size. The number of raindrops may increase so rapidly in this manner that after a few minutes the accumulated mass of water can no longer be supported by the upcurrents and falls as a heavy shower. These conditions occur more readily in tropical regions. In temperate regions where the 0° C level is much lower in elevation, conditions are more favourable for the ice-crystal mechanism.

Growth of hailstones

The hailstones that fall from deep, vigorous clouds in warm weather consist of a core surrounded by several al-

Figure 11: *Low clouds.*

ternate layers of clear and opaque ice. When the growing particle traverses a region of relatively high air temperature or high concentration of liquid water, or both, the transfer of heat from the hailstone to the air cannot occur rapidly enough to allow all of the deposited water to freeze immediately. This results in the formation of a wet coating of slushy ice, which may later freeze to form a layer of compact, relatively transparent ice. If the hailstone then enters a region of lower temperature and lower water content, the impacting droplets may freeze individually to produce ice of relatively low density with air spaces between the droplets. The alternate layers are formed as the stone passes through regions in which the combination of air temperature, liquid-water content, and updraft speed allows alternately wet and dry growth.

It is held by some authorities that lightning is closely associated with the appearance of precipitation, especially in the form of soft hail (see below), and that the charge and strong electric fields are produced by ice crystals or cloud droplets impacting on and bouncing off the undersurfaces of the hail pellets. For a detailed discussion of electrical effects in clouds, see below *Thunderstorms.*

TYPES OF PRECIPITATION

Drizzle. Liquid precipitation in the form of very small drops, with diameters between 0.2 and 0.5 millimetre and terminal velocities between 70 and 200 centimetres per second, is defined as drizzle. It forms by the coalescence of even smaller droplets in low layer clouds containing weak updrafts of only a few centimetres per second. High relative humidity below the cloud base is required to prevent the drops from evaporating before reaching the ground; drizzle is classified as slight, moderate, or thick. Slight drizzle produces negligible runoff from the roofs of buildings, and thick drizzle accumulates at a rate in excess of one millimetre per hour.

Rain and freezing rain. Liquid waterdrops with diameters greater than those of drizzle constitute rain. Raindrops rarely exceed six millimetres in diameter because they become unstable when larger than this and break up during their fall. The terminal velocities of raindrops at ground level range from two metres per second for the smallest to about 10 metres per second for the largest. The smaller raindrops are kept nearly spherical by surface-tension forces, but, as the diameter surpasses about two millimetres, they become increasingly flattened by aerodynamic forces. When the diameter reaches six millimetres, the undersurface of the drop becomes concave because of the airstream and the surface of the drop is sheared off to form a rapidly expanding bubble or bag attached to an annular ring containing the bulk of the water. Eventually the bag bursts into a spray of fine droplets and the ring breaks up into a circlet of millimetre-sized drops.

Rain of a given intensity is composed of a spectrum of drop sizes, the average and median drop diameters being larger in rains of greater intensity. The largest drops, which have a diameter greater than five millimetres, appear only in the heavy rains of intense storms.

When raindrops fall through a cold layer of air (colder than 0° C) and become supercooled, freezing rain occurs. The drops may freeze on impact with the ground to form a very slippery and dangerous "glazed" ice that is difficult to see because it is almost transparent.

Snow and sleet. Snow in the atmosphere can be subdivided into ice crystals and snowflakes. Ice crystals generally form on ice nuclei at temperatures appreciably below

the freezing point. Below −40° C water vapour can solidify without the presence of a nucleus. Snowflakes are aggregates of ice crystals that appear in an infinite variety of shapes, mainly at temperatures near the freezing point of water.

In British terminology, sleet is the term used to describe precipitation of snow and rain together or of snow melting as it falls. In the United States, it is used to denote partly frozen ice pellets.

Physical properties and conditions of formation

Snow crystals generally have a hexagonal pattern, often with beautifully intricate shapes. Three- and 12-branched forms occur occasionally. The hexagonal form of the atmospheric ice crystals, their varying size and shape notwithstanding, is an outward manifestation of an internal arrangement in which the oxygen atoms form an open lattice (network) with hexagonally symmetrical structure. According to a recent internationally accepted classification there are seven types of snow crystals: plates, stellars, columns, needles, spatial dendrites, capped columns, and irregular crystals. They are shown in Figure 12. The size and shape of the snow crystals depend mainly on the temperature of their formation and on the amount of water vapour that is available for deposition. The two principal influences are not independent; the possible water vapour admixture of the air decreases strongly with decreasing temperature. The vapour pressure in equilibrium with a level surface of pure ice is 50 times greater at −2° C than at −42° C, the likely limits of snow formation in the air. Crystal shape and temperature at formation are related in Table 2.

Table 2: Relation of Crystal Shape and Temperature at Formation

temperature (°C)	form	temperature (°C)	form
0 to −3	thin hexagonal plates	−12 to −16	dendritic crystals
3 to −5	needles	−16 to −25	hexagonal plates
−5 to −8	hollow, prismatic columns	−25 to −50	hollow prisms
−8 to −12	hexagonal plates		

At temperatures above about −40° C, the crystals form on nuclei of very small size that float in the air (heterogeneous nucleation). The nuclei consist predominantly of silicate minerals of terrestrial origin, mainly clay minerals and micas. At still lower temperatures ice may form directly from water vapour (homogeneous nucleation). The influence of the atmospheric water vapour depends mainly on its degree of supersaturation with respect to ice.

Snow and ice crystals in clouds

If the air contains a large excess of water vapour, the snow particles will grow fast and there may be a tendency for dendritic (branching) growth. With low temperature the excess water vapour tends to be small, and the crystals remain small. In relatively dry layers the snow particles generally have simple forms. Complicated forms of crystals will cling together with others to form snowflakes that consist occasionally of up to 100 crystals; the diameter of such flakes may be as large as 2.5 centimetres. This process will be furthered if the crystals are near freezing point and wet, possibly by collision with undercooled water droplets. If a crystal falls into a cloud with great numbers of such drops, it will sweep some of them up. Coming into contact with ice, they freeze and form an ice cover around the crystal. Such particles are called soft hail or graupel (see below).

Snow particles constitute the clouds of cirrus type—namely cirrus, cirrostratus, and cirrocumulus, and many clouds of alto type. Ice and snow clouds originate normally only at temperatures some degrees below the freezing point; they predominate at −20° C. In temperate and low latitudes these clouds occur in the higher layers of the troposphere. In tropical regions they hardly ever occur below 4,570 metres. On high mountains and particularly in polar regions, they can occur near the surface and may appear as ice fogs. If cold air near the ground is overlain by warmer air (a very common occurrence in polar regions, especially in winter), mixture at the border leads to supersaturation in the cold air. Small ice columns and needles, "diamond dust," will be formed and float down, glittering, even from a cloudless sky. In the coldest parts of Antarctica where temperatures near the surface are below −50° C on the average and rarely above −30° C, the formation of diamond dust is a common occurrence. The floating and falling ice crystals produce in the light of the Sun and Moon the manifold phenomena of atmospheric optics, halos, arcs, circles, mock suns, some coronas, and iridescent clouds. Most of the different optical appearances can be explained by the shapes of the crystals and their position with respect to the light source.

Diamond dust

Most of the moderate to heavy rain in temperate latitudes depends on the presence of ice and snow particles in clouds. In the free atmosphere, droplets of fluid water can be undercooled considerably; typical ice clouds originate mainly at a temperature near −20° C. At an identical temperature below freezing point the water molecules are kept more firmly in the solid than in the fluid state. The equilibrium pressure of the gaseous phase is smaller in contact with ice than with water. At −20° C, which is the temperature of the formation of typical ice clouds (cirrus), the equilibrium pressure with respect to undercooled water (relative humidity 100 percent) is 22 percent greater than the equilibrium pressure of the water vapour in contact with ice. Hence, with an excess of water vapour beyond the equilibrium state, the ice particles tend to incorporate more water vapour and to grow more rapidly than the water droplets.

Being larger and so less retarded by friction, the ice par-

Vincent J. Schaefer

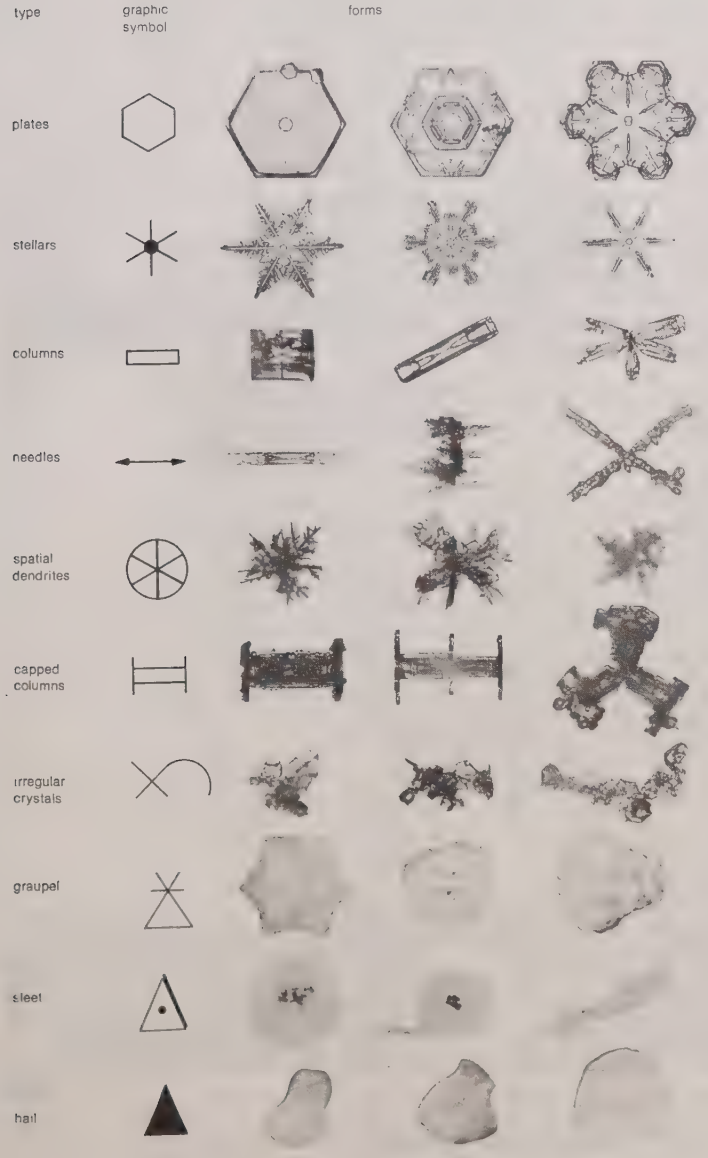

Figure 12: Classification of frozen precipitation.

ticles fall more rapidly. In their fall they sweep up some water droplets, which on contact become frozen. Thus a cloud layer originally consisting mainly of undercooled water with few ice crystals is transformed into an ice cloud. The development of the anvil shape at the top of a towering cumulonimbus cloud shows this transformation very clearly. The larger ice particles overcome more readily the rising tendency of the air in the cloud. Falling into lower levels they grow, aggregating with other crystals and possibly with water drops, melt, and form raindrops when near-surface temperatures permit.

Types of hail

Hail. Solid precipitation in the form of hard pellets of ice that fall from cumulonimbus clouds is hail. It is convenient to distinguish among three types of hail particles.

The first is soft hail, or snow pellets, which are white, opaque, rounded or conical pellets as large as six millimetres in diameter. They are composed of small cloud droplets frozen together, have a low density, and are readily crushed.

Second is small hail (ice grains or pellets), transparent or translucent pellets of ice that are spherical, spheroidal, conical, or irregular in shape, with diameters of a few millimetres. They may consist of frozen raindrops, of largely melted and refrozen snowflakes, or of snow pellets encased in a thin layer of solid ice.

True hailstones, the third type, are hard pellets of ice, larger than five millimetres in diameter, that may be spherical, spheroidal, conical, discoidal, or irregular in shape and often have a structure of concentric layers of alternately clear and opaque ice (Figure 13). A moderately severe storm may produce stones a few centimetres in diameter, whereas a very severe storm may release stones with a maximum diameter of 10 centimetres or more. Large damaging hail falls most frequently in the continental areas of middle latitudes (*e.g.*, in the Nebraska–Wyoming–Colorado area of the United States, in South Africa, and in northern India) but is rare in equatorial regions. Terminal velocities of hailstones range from about five metres per second for the smallest stones to perhaps 40 metres per second for stones five centimetres in diameter.

WORLD DISTRIBUTION OF PRECIPITATION

Regional and latitudinal distribution. The yearly precipitation averaged over the whole Earth is about 100 centimetres, but this is distributed very unevenly. The regions of highest rainfall are found in the equatorial zone and the monsoon area of Southeast Asia (Figure 14). Middle latitudes receive moderate amounts of precipitation, but little falls in the desert regions of the subtropics and around the poles.

From H.H. Lamb, *Climate: Present, Past and Future*, Methuen & Co Ltd

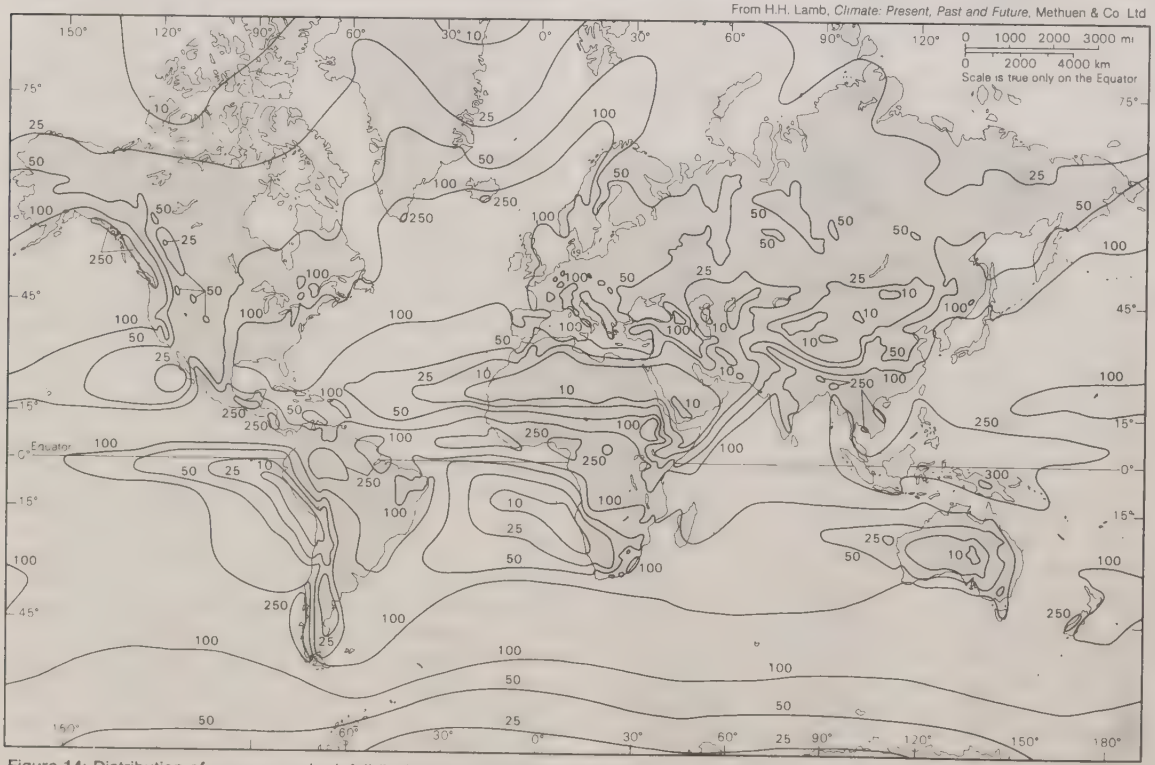

Figure 14: Distribution of mean annual rainfall (including snowmelt) in centimetres.

If the Earth's surface were perfectly uniform, the long-term average rainfall would be distributed in distinct latitudinal bands, but the situation is complicated by the pattern of the global winds, the distribution of land and sea, and the presence of mountains. Because rainfall results from the ascent and cooling of moist air, the areas of heavy rain indicate regions of rising air, whereas the deserts occur in regions in which the air is warmed and dried during descent. In the subtropics, the trade winds bring plentiful rain to the east coasts of the continents, but the west coasts tend to be dry. On the other hand, in high latitudes the west coasts are generally wetter than the east coasts. Rain tends to be abundant on the windward slopes of mountain ranges but sparse on the lee sides.

Equatorial and desert regions

In the equatorial belt, the trade winds from both hemispheres converge and give rise to a general upward motion of air, which becomes intensified locally in tropical storms that produce very heavy rains in the Caribbean, the Indian and southwest Pacific oceans, and the China Sea, and in thunderstorms that are especially frequent and active over the land areas. During the annual cycle, the doldrums move toward the summer hemisphere so that, outside a central region near the Equator, which has abundant rain at all seasons, there is a zone that receives much rain in summer but a good deal less in winter.

The dry areas of the subtropics, such as the desert regions of North Africa, the Arabian Peninsula, South Africa, Australia, and central South America, are due to the presence of semipermanent, subtropical anticyclones in which the air subsides and becomes warm and dry. These high-pressure belts tend to migrate with the seasons and cause summer dryness on the poleward side and winter dryness on the equatorward side of their mean positions (see below *Cyclones and anticyclones*). The easterly trade winds, having made a long passage over the warm oceans, bring plentiful rains to the east coasts of the subtropical landmasses, but the west coasts and the interiors of the continents, which are often sheltered by mountain ranges, are very dry.

Middle and high latitudes

In middle latitudes the weather and the rainfall are dominated by traveling depressions and fronts that yield a good deal of rain in all seasons and in most places except the far interiors of the Asian and North American continents. Generally the rainfall is more abundant in summer, except on the western coasts of North America, Europe, and North Africa, where it is higher during the winter.

At high latitudes and especially in the polar regions, the low precipitation is caused partly by subsidence of air in the high-pressure belts and partly by the low temperatures. Snow or rain occur at times (see Figures 14 and 15), but evaporation from the cold sea and land surfaces is slow, and the cold air has little capacity for moisture.

The influence of oceans and continents on rainfall is particularly striking in the case of the Indian monsoon. During the Northern Hemisphere winter, cool, dry air from the interior of the continent flows southward and produces little rain over the land areas. After the air has traveled some distance over the warm tropical ocean, however, it releases heavy shower rains over the East Indies. During the northern summer, when the monsoon blows from the southwest, rainfall is heavy over India and Southeast Asia. These rains are intensified where the air is forced to ascend over the windward slopes of the Western Ghāts and the Himalayas.

The combined effects of land, sea, mountains, and prevailing winds show up in South America. There the desert in southern Argentina is sheltered by the Andes from the westerly winds blowing from the Pacific Ocean, and the west-coast desert is not only situated under the South Pacific subtropical anticyclone but is also protected by the Andes against rain-bearing winds from the Atlantic.

Amounts and variability. The long-term average

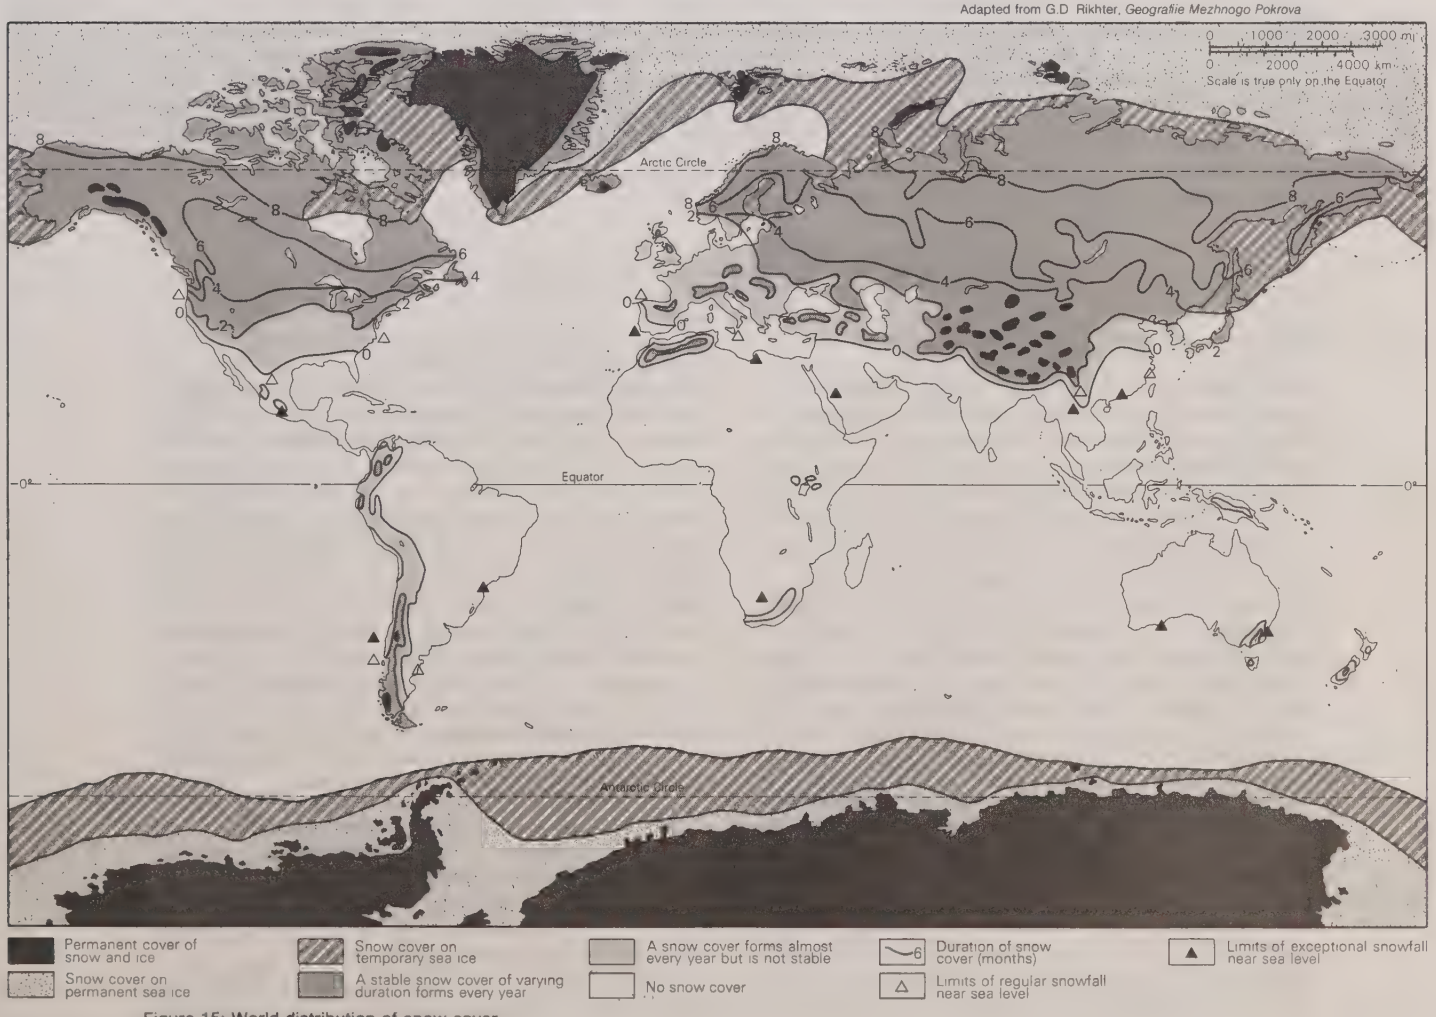

Figure 15: World distribution of snow cover.

amounts of precipitation for a season, or a year, give little information on the regularity with which rain may be expected, particularly for regions where the average amounts are small. For example, at Iquique, in northern Chile, four years once passed without rain, whereas the fifth year gave 15 millimetres; the five-year average was therefore three millimetres. Clearly, such averages are of little practical value, and the frequency distribution or the variability of precipitation also must be known.

Relation of variability and average amount

The variability of the annual rainfall is closely related to the average amounts. For example, over the British Isles, which have a very dependable rainfall, the annual amount varies by less than 10 percent above the long-term average value. A variability of less than 15 percent is typical of the mid-latitude cyclonic belts of the Pacific and Atlantic oceans and of much of the wet equatorial regions. In the interiors of the desert areas of Africa, Arabia, and Central Asia, however, the rainfall in a particular year may deviate from the normal long-term average by more than 40 percent. The variability for individual seasons or months may differ considerably from that for the year as a whole, but again the variability tends to be higher where the average amounts are low.

The heaviest annual rainfall in the world was recorded at Cherrapunji, India, where 26,470 millimetres fell between August 1860 and July 1861. The heaviest rainfall in a period of 24 hours was 1,870 millimetres recorded at Cilaos, Réunion, in the Indian Ocean on March 15–16, 1952. The lowest recorded rainfall in the world occurred at Arica, in northern Chile. An annual average, taken over a 43-year period, was only 0.5 millimetre.

Although past records give some guide, it is not possible to estimate very precisely the maximum possible precipitation that may fall in a given locality during a specified interval of time. Much will depend on a favourable combination of several factors, including the properties of the storm and the effects of local topography. Thus it is possible only to make estimates that are based on analyses of past storms or on theoretical calculations that attempt to maximize statistically the various factors or the most effective combination of factors that are known to control the duration and intensity of the precipitation. For many important planning and design problems, however, estimates of the greatest precipitation to be expected at a given location within a specified number of years are required.

In the design of a dam, the highest 24-hour rainfall to be expected once in 30 years over the whole catchment area might be relevant. For dealing with such problems, a great deal of work has been devoted to determining, from past records, the frequency with which rainfalls of given intensity and total amount may be expected to reoccur at particular locations and also to determining the statistics of rainfall for a specific area from measurements made at only a few points.

EFFECTS OF PRECIPITATION

Raindrop impact and soil erosion. Large raindrops, up to six millimetres in diameter, have terminal velocities of about 10 metres per second and so may cause considerable compaction and erosion of the soil by their force of impact. The formation of a compacted crust makes it more difficult for air and water to reach the roots of plants and encourages the water to run off the surface and carry away the topsoil with it. In hilly and mountainous areas, heavy rain may turn the soil into mud and slurry, which may produce enormous erosion by mudflow generation. Rainwater running off hard, impervious surfaces or waterlogged soil may cause local flooding.

Surface runoff. The rainwater that is not evaporated or stored in the soil eventually runs off the surface and finds its way into rivers, streams, and lakes or percolates through the rocks and becomes stored in natural underground reservoirs. A given catchment area must achieve an overall balance such that precipitation (P) less evaporation of moisture from the surface (E) will equal storage in the ground (S) and runoff (R). This may be expressed: $P - E = S + R$. The runoff may be determined by measuring the flow of water in the rivers with stream gauges, and the precipitation measured by a network of rain gauges, but storage and evaporation are more difficult to estimate.

Of all the water that falls on the Earth's surface, the relative amounts that run off, evaporate, or seep into the ground vary so much for different areas that no firm figures can be given for the Earth as a whole. It has been estimated, however, that in the United States 10 to 50 percent of the rainfall runs off at once, 10 to 30 percent evaporates, and 40 to 60 percent is absorbed by the soil. Of the entire rainfall, 15 to 30 percent is estimated to be used by plants, either to form plant tissue or in transpiration. (B.J.M./F.P.L./Ed.)

ATMOSPHERIC PRESSURE AND WIND

Atmospheric pressure

Atmospheric pressure and wind are both significant controlling factors in the Earth's weather and climate. Although these two physical variables may at first glance appear to be quite different, they are in fact closely related. Wind exists because of horizontal and vertical differences (gradients) in pressure, yielding a correspondence that often makes it possible to use the pressure distribution as an alternative representation of atmospheric motions. Pressure is the force exerted on a unit area, and atmospheric pressure is equivalent to the weight of air above a given area on the Earth's surface or within its atmosphere. This pressure is usually expressed in millibars (one mb equals 1,000 dynes per square centimetre) or in kilopascals (kPa; one kPa equals 10,000 dynes per square centimetre). Distributions of pressure on a map are depicted by a series of curved lines called isobars, each of which connects points of equal pressure.

At sea level, the mean pressure is about 1,000 millibars (100 kilopascals), varying by less than 5 percent from this value at any given location or time. Figures 16 and 17 show mean sea-level pressure for the mid-winter and mid-summer months. Since these charts represent average values over several days, pressure features that are relatively consistent day after day emerge, while more transient, short-lived features are removed. Those that remain are known as semi-permanent pressure centres and are the source regions for major, relatively uniform bodies of air known as air masses. Warm, moist maritime tropical (mT) air forms over tropical or subtropical ocean waters in association with the high-pressure regions prominent there. Cool, moist maritime polar (mP) air, on the other hand, forms over the colder subpolar ocean waters just south and east of the large, winter oceanic low-pressure regions. Over the continents, cold, dry continental polar (cP) air forms in the high-pressure regions that are especially pronounced in winter, while hot, dry continental tropical (cT) air forms over hot, desertlike continental domains in summer in association with low-pressure areas sometimes called heat lows.

Air masses

A closer examination of Figures 16 and 17 reveals some interesting features. First, it is clear that sea-level pressure is dominated by closed high- and low-pressure centres, which are largely caused by differential surface heating between low and high latitudes and between continental and oceanic regions. High pressure tends to be amplified over the colder surface features. Second, because of seasonal changes in surface heating, the pressure centres exhibit seasonal changes in their characteristics. For example, the Siberian High, Aleutian Low, and Icelandic Low that are so prominent in the winter virtually disappear in summer as the continental regions warm relative to surrounding bodies of water. At the same time, the Pacific and Atlantic highs amplify and migrate northward.

At altitudes well above the Earth's surface (Figure 18), the monthly average pressure distributions show much less tendency to form in closed centres but rather ap-

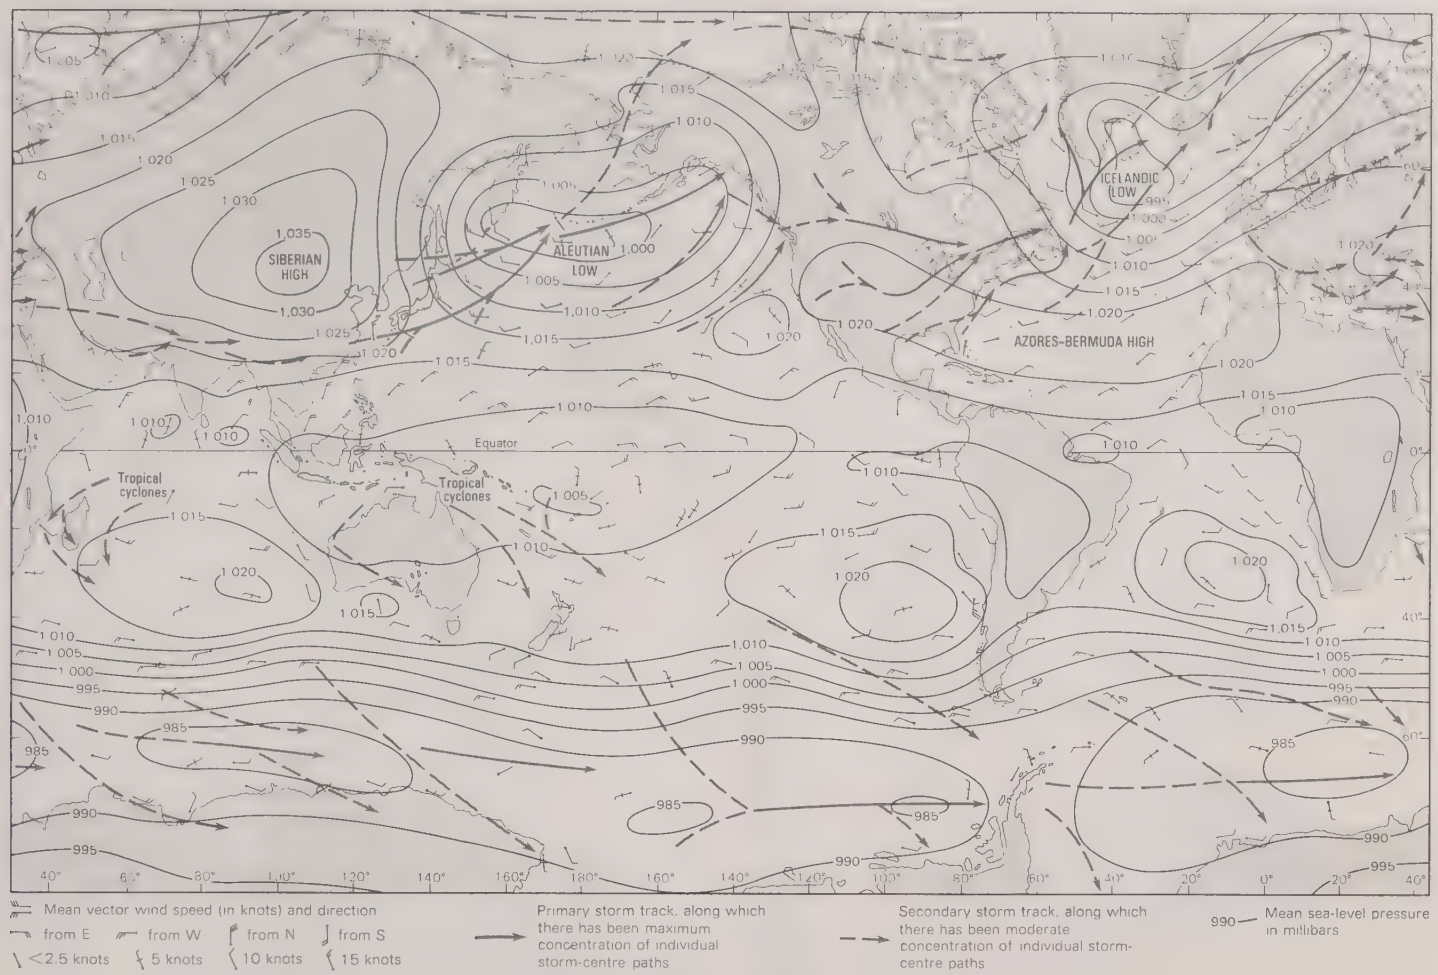

Figure 16: World distribution of mean sea-level pressure (in millibars) for January, and primary and secondary storm tracks. The general character of the global winds is also shown.
From H.L. Crutcher and O.M. Davis, *Navy Marine Climatic Atlas of the World*, vol. 8, NAVAIR 50-1C-54; U.S. Naval Weather Service Command

pear as quasi-concentric circles around the poles. This more symmetrical appearance reflects the dominant role of meridional radiative heating/cooling differences. Excess heating in tropical latitudes, compared to the polar, produces higher pressure at upper levels in the tropics. In addition, the greater heating/cooling contrast in winter yields stronger pressure differences during this season. Perfect symmetry is interrupted by superimposed wavelike disturbances. These are most pronounced over the Northern Hemisphere, with its more prominent land-ocean contrasts and orographic features.

Wind

RELATIONSHIP OF WIND TO PRESSURE AND GOVERNING FORCES

The changing wind patterns are governed by Newton's second law of motion, which states that the sum of the forces acting on a body equals the product of the mass of that body and the acceleration caused by those forces. The basic relationship between atmospheric pressure and horizontal wind is revealed by disregarding friction and any changes in wind direction and speed to yield the mathematical relationship

$$fu = -\frac{1}{\rho}\frac{\partial p}{\partial y} \text{ and } fv = \frac{1}{\rho}\frac{\partial p}{\partial x}, \qquad (1)$$

where u is the zonal wind speed (+ eastward), v the meridional wind speed (+ northward), $f = 2\omega \sin \varphi$ (Coriolis parameter), ω the angular velocity of the Earth's rotation, φ the latitude, ρ the air density (mass per unit volume), p the pressure, and x and y the distances toward the east and north, respectively. This simple, non-accelerating flow is known as geostrophic balance and yields a motion field known as the geostrophic wind. Equation (1) expresses, for both the x and y directions, a balance between the force created by horizontal differences in pressure (the horizontal pressure-gradient force) and the force that results from the Earth's rotation (the Coriolis force), as depicted is Figure 19. The pressure-gradient force expresses the tendency of pressure differences to effectuate air movement from higher to lower pressure. The Coriolis force is a more complicated concept that arises because the air motions are observed on a rotating, nearly spherical body. The total motion of a parcel of air has two parts: (1) the motion relative to the Earth as if the Earth were fixed, and (2) the motion given to the parcel by the planet's rotation. If an observer viewed the atmosphere from a fixed point in space, the rotation of the Earth would be apparent to him and he would observe the total motion. An observer on the ground, however, sees and measures only the relative motion and, as he also is rotating, cannot see directly the rotational motion applied by the Earth. Instead, he sees the effect of the rotation as a deviation applied to the relative motion. The quantity that causes this deviation is the so-called Coriolis force. More specifically, what the observer sees is a deflection of the relative motion to the right in the Northern Hemisphere and to the left in the Southern Hemisphere. Of particular significance in this simple model of wind–pressure relationships is the fact that the geostrophic wind blows in a direction parallel to the isobars with the low pressure on the observer's left as he looks downwind in the Northern Hemisphere and on his right in the Southern Hemisphere. Furthermore, the wind speed increases as the distance between isobars decreases (or pressure gradient increases). Curvature (*i.e.*, changes in wind direction) can be added to this model with relative

Geostrophic wind

Coriolis force

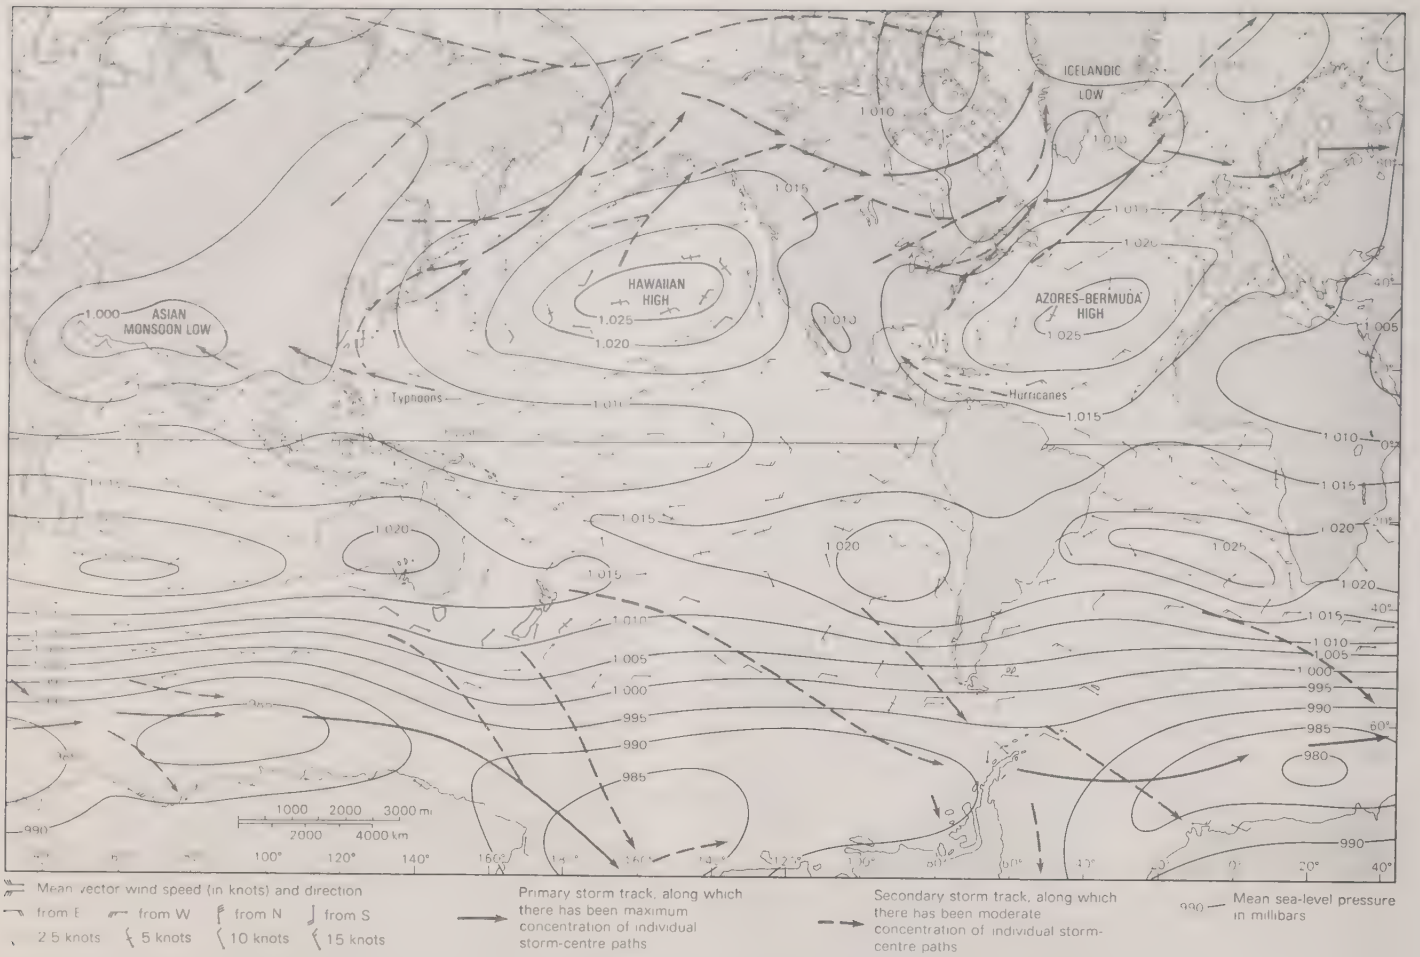

Figure 17: World distribution of mean sea-level pressure (in millibars) for July, and primary and secondary storm tracks. The general character of the global winds is also shown.
From H.L. Crutcher and O.M. Davis, *Navy Marine Climatic Atlas of the World*, vol. 8, NAVAIR 50-1C-54; U.S. Naval Weather Service Command

ease in a flow representation known as the gradient wind. The basic wind–pressure relationships, however, remain qualitatively the same. Of greatest importance is the fact that actual observed winds tend to behave much as the geostrophic- or gradient-flow models predict in most of the atmosphere.

The most notable exceptions are in low latitudes where the Coriolis parameter becomes very small and thus equation (1) cannot be used to provide a reliable wind estimate, and in the lowest kilometre of the atmosphere where friction becomes important. The friction induced by flow over the underlying surface reduces the wind speed and alters the simple balance of forces depicted in Figure 19 such that the wind blows with a component toward lower pressure, as shown in Figure 20.

CYCLONES AND ANTICYCLONES

Simply stated, cyclones and anticyclones are regions of relatively low and high pressure, respectively. They occur over most of the Earth in a variety of sizes ranging from the very large, semipermanent examples described above to smaller, highly mobile systems. The latter are the focus of discussion in this section.

Common to both cyclones and anticyclones are the characteristic circulation patterns. The geostrophic-flow model (see above) dictates that in the Northern Hemisphere flow around a cyclone—cyclonic circulation—is counterclockwise and flow around an anticyclone—anticyclonic circulation—is clockwise (Figure 21). Circulation directions are reversed in the Southern Hemisphere (see Figures 16 and 17). In the presence of friction, the superimposed component of motion toward lower pressure produces a "spiraling" motion in toward the low centre and out away from the high centre.

The cyclones that form outside the equatorial belt, known as extratropical cyclones, may be regarded as large eddies in the broad air currents that flow in the general direction from west to east around the middle latitudes of both hemispheres (see below). They are an essential part of the mechanism by which the excess heat received from the Sun in the equatorial belt is conveyed toward higher latitudes. These higher latitudes radiate more heat to space than they receive from the Sun, and heat must reach them by winds from the equatorial belt if their temperature is to be maintained. If there were no cyclones and anticyclones, the north–south movements of the air would be much more limited, and there would be little opportunity for heat to be carried poleward by winds of subtropical origin. Under such circumstances the temperature of the equatorial regions would increase and the polar regions would cool; the temperature gradient between them would intensify.

Strong horizontal gradients of temperature are particularly favourable for the formation and development of cyclones. In the absence of cyclones and anticyclones the temperature difference between pole and Equator would tend to build up until it was sufficiently intense to generate new cyclones. The new cyclones themselves, however, would tend to reduce the temperature difference. Thus, the wind circulation on the Earth represents a balance between the effect of solar radiation in building a temperature difference between pole and Equator, and the effect of cyclones, anticyclones, and other wind systems in destroying this temperature contrast.

Cyclones of a somewhat different character occur closer to the Equator, forming in latitudes 10° to 15° N and S over the oceans. They generally are known as tropical cyclones but, more specifically, as hurricanes in the Atlantic and Caribbean, as typhoons in the western Pacific and China Sea, and as willy-willies off the coasts of Australia.

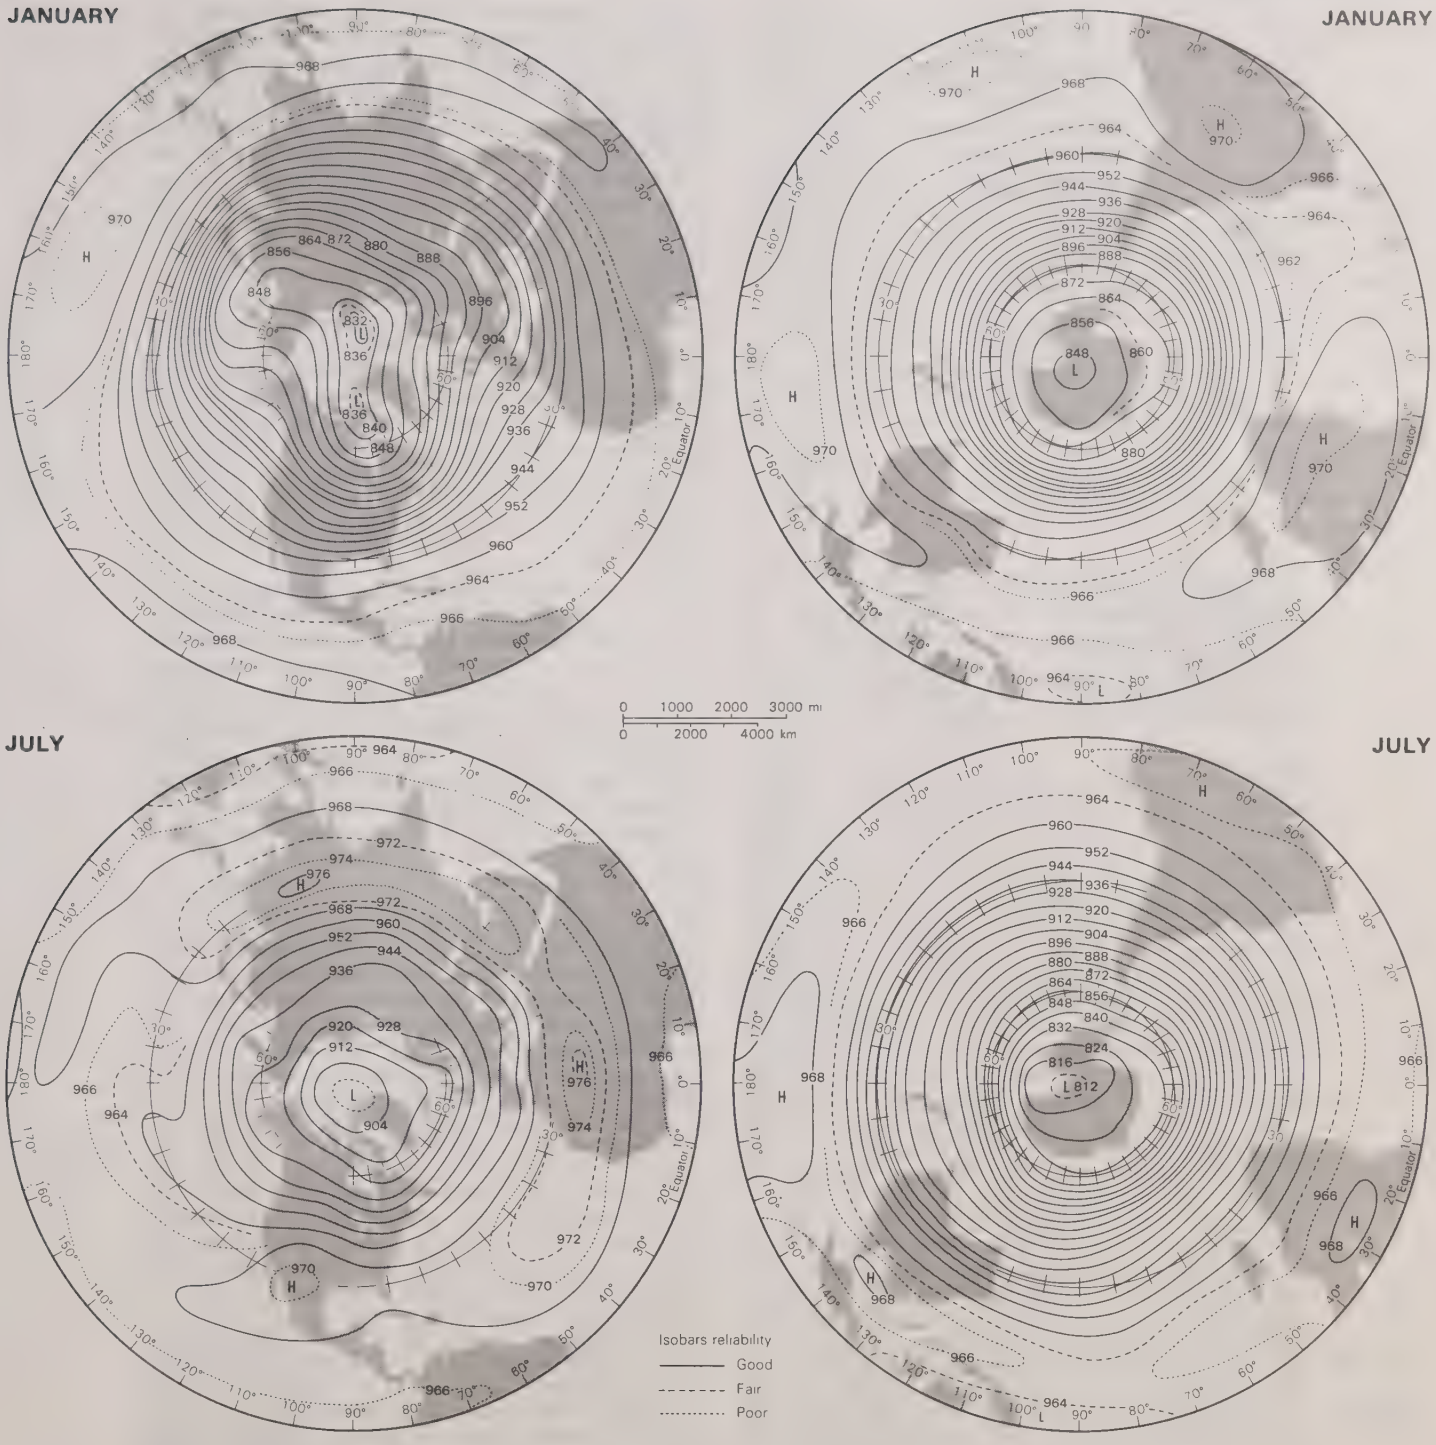

Figure 18: *Contours on the surface for which the pressure is 300 millibars.* Winds of the upper troposphere parallel these isobars. Note (left) the more marked seasonal change in pattern in the Northern Hemisphere.

From H.L. Crutcher, R.L. Jenne, H. van Loon, and J.J. Taljaard, *Climate of the Upper Air*, part 1, *Southern Hemisphere*, NAVAIR 50-1C-55; U.S. Naval Weather Service Command

These storms are of smaller diameter than the extratropical cyclones, ranging from 100 to 500 kilometres in diameter, and are accompanied by winds that sometimes reach extreme violence. These storms are more fully described below in the section *Hurricanes and typhoons*.

Extratropical cyclones. Of the various examples of transient cyclones, extratropical cyclones are the most abundant and exert influence on the broadest scale, affecting the largest percentage of the Earth's surface. Furthermore, this class of cyclones is the principle cause of day-to-day weather changes experienced in middle and high latitudes and thus is the focal point of much of modern weather forecasting. The seeds for many current ideas concerning extratropical cyclones were sown between 1912 and 1930 by a group of Scandinavian meteorologists working in Bergen, Nor. This so-called Bergen school, founded by Vilhelm Bjerknes, formulated a model for a cyclone that forms as a disturbance along a zone of strong temperature contrast known as a front, which in turn constitutes a boundary between two contrasting air masses.

The model of the Bergen school

In this model proposed by the Bergen school, the masses of polar and mid-latitude air around the globe are separated by the polar front. The area bounding this region of strong temperature gradient has a reservoir of potential energy that can be readily tapped and converted into the kinetic energy associated with extratropical cyclones. For this reservoir to be tapped, a cyclone (called a wave, or frontal, cyclone) must develop much in the way shown in Figure 22. The feature that is of primary importance prior to cyclone development (cyclogenesis) is a front,

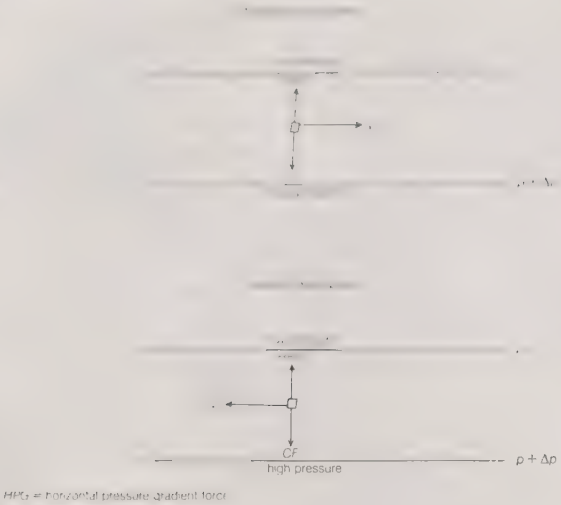

Figure 19: *Balance of forces and resulting geostrophic wind.* A gradient is the rate of decrease of a quantity per unit distance over which that decrease occurs. It should be noted that *HPG* and *CF* are of equal magnitude but act in opposite directions (balanced forces) and that V_g is perpendicular to both forces. Moreover, *HPG* acts from high to low pressure (p), and *CF* acts to the right of V_g in the Northern Hemisphere and to the left in the Southern Hemisphere.

represented in Figure 22A as a heavy black line with alternating triangles or semicircles attached to it. This stationary or very slow-moving front forms a boundary between cold and warm air and so is a zone of strong horizontal temperature gradient (sometimes referred to as a baroclinic zone). Cyclone development is initiated as a disturbance along the front, which distorts the front into the wavelike configuration (22B). As the pressure within the disturbance continues to decrease, the disturbance assumes the appearance of a small cyclone and forces northward and southward movements of warm and cold air, respectively, which are represented by mobile frontal boundaries. As depicted in 22C, the front that signals the advancing cold air (cold front) is indicated by the triangles, while the front corresponding to the advancing warm air (warm front) is indicated by the semicircles. As the cyclone continues to intensify (22D), the cold, dense air streams rapidly southward, yielding a cold front with a typical slope of one to 50 and a propagation speed of eight to 15 metres per second (about 15 to 30 knots). At the same time, the warm, less dense air moving in a northerly direction flows up over the cold air east of the cyclone to produce a warm front with a typical slope of one to 200 and a much slower propagation speed of 2.5 to eight metres per second. This difference in propagation speeds allows the cold front to overtake the warm front to produce yet another, more complicated frontal structure known as an occluded front (22E, with alternating triangles and semicircles on the same side). This occlusion process may be followed by further storm intensification. The separation of the cyclone from the warm air to the south, however, eventually leads to the storm's decay (cyclolysis).

Occluded front

The life cycle of such an event is typically several days, during which the cyclone may travel from several hundred to a few thousand kilometres. In its path and wake occur dramatic weather changes. A typical sequence of weather that might be experienced as a cyclone and its fronts approach and pass through an area is depicted in Figure 23. Shown here is a cross section of the clouds and precipitation that usually occur along line *ab* in Figure 22D. Warm frontal weather is characterized by stratiform clouds, which descend as the front approaches and which eventually yield rain or snow. The passing of a warm front brings a rise in air temperature and clearing skies. The warmer air, however, may also harbour the ingredients for rain shower or thunderstorm formation, a condition that is enhanced as the cold front approaches. The passage of the cold front is marked by the influx of colder air, formation of stratocumulus cloud with some lingering rain or snow showers, and then eventual clearing. While this is an oft-repeated scenario, it is important to recognize that many other weather sequences can occur. For example, the stratiform clouds of a warm front may have imbedded cumulus formations and thunderstorms; the warm sector might be quite dry and yield few or no clouds; the pre-cold-front weather may closely resemble that found ahead of the warm front; or the post-cold-front air may be completely cloud-free. Cloud patterns oriented along fronts and spiraling around the cyclone vortex are consistently revealed in satellite pictures of the Earth (Figure 24).

The actual formation of any area of low pressure requires that mass in the column of air lying above the Earth's surface be reduced. This loss of mass then reduces the surface pressure. In the late 1930s and early 1940s, three members of the Bergen school, Jacob Bjerknes, J. Holmboe, and Carl-Gustaf Rossby, recognized that transient surfaces disturbances were accompanied by complementary wave features in the flow in the middle and higher atmospheric layers. These wave features (see below) are accompanied by regions of mass divergence and convergence that support the growth of surface-pressure fields and direct their movement.

While extratropical cyclones often form, intensify, or both in association with fronts, there are some that appear in the middle of a single air mass. A notable example is a class of cyclones, generally smaller than the frontal variety, that form in polar air streams in the wake of a frontal cyclone. These so-called polar lows are most prominent in subpolar marine environments and are thought to be caused by the transfer of heat and moisture from the warmer water surface into the overlying polar air and by supporting middle-tropospheric circulation features. Other cyclones form on the lee side of mountain barriers as the general westerly flow is disturbed by the mountain.

Polar lows

Anticyclones. While cyclones are typically regions of inclement weather induced by upward motions of five to 10 centimetres per second, anticyclones are usually meteorologically quiet regions. Generally larger than cyclones, anticyclones exhibit downward motions of one to three centimetres per second and yield dry stable air that may extend horizontally many hundreds of kilometres.

In most cases, an actively developing anticyclone forms in the region of cold air behind a cyclone as it moves away and before the next cyclone advances. Such an anticyclone is known as a cold anticyclone. A result of the downward air motion in an anticyclone, however, is compression of the descending air, and as a consequence of this compression the air is warmed. Thus after a few days the air composing the anticyclone at levels two to five kilometres above the ground tends to increase in temperature, and the anticyclone is transformed into a warm anticyclone. The air near the ground cannot descend and is not much affected by this process.

Types of anticyclones

Warm anticyclones move slowly, and cyclones are diverted around their periphery. During their transformation from cold to warm anticyclones, they usually move out of the main belt followed by cyclones in middle latitudes, often amalgamating with the quasi-permanent band of relatively high pressure that is found in both hemispheres around latitude 20° to 30°—the so-called subtropical anticyclones. On some occasions the warm anticyclones remain in the belt normally occupied by the mid-latitude westerly winds. The normal tracks of cyclones are then

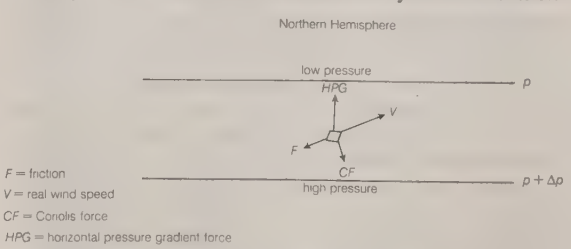

Figure 20: *Balance of forces with friction (F) included.* It can be seen that *V* has a component toward lower pressure and that *CF* remains perpendicular to *V* but is no longer equal and opposite to *HPG*.

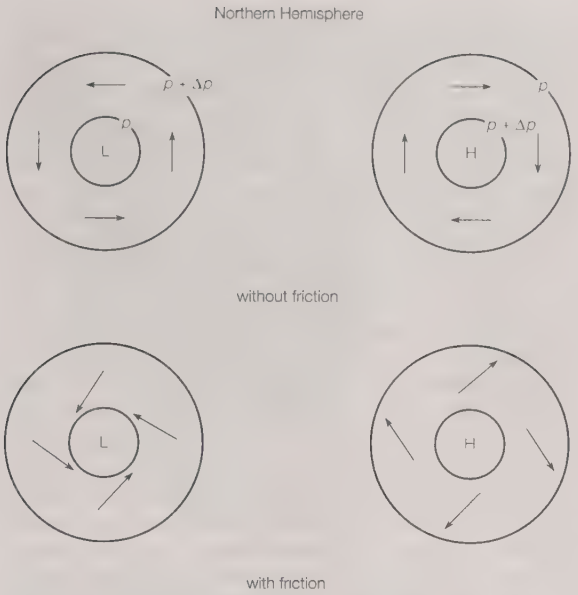

Figure 21: *Idealized depiction of flow around low (L) and high (H) pressure centres in the absence and presence of friction.* The solid lines are isobars. The arrows indicate the direction of flow in the Northern Hemisphere.

considerably modified; depressions are either blocked in their eastward progress or diverted to the north or south of the anticyclone. Anticyclones that interrupt the normal circulation of the westerly wind in this way are blocking anticyclones. They frequently persist for a week or more, and the occurrence of a few such blocking anticyclones may dominate the character of a season. Blocking anticyclones are particularly common over Europe, the eastern Atlantic, and the Alaskan area.

The descent and warming of the air in an anticyclone might be expected to lead to the dissolution of clouds and the absence of rain. This occurs often, particularly in summer. Since the air near the ground cannot take part in the descent, it may become stagnant. In winter the ground cools and the lower layers of the atmosphere also become cold. Fog may be formed as the air is cooled to its dew point. Under other circumstances the air trapped in the first kilometre above the surface may pick up moisture from the sea or moist surfaces, and layers of cloud may form from near the ground to a height of about one kilometre. Such layers of cloud can be persistent in anticyclones (except over the continents in summer), but they rarely grow thick enough to produce rain. If precipitation occurs, it is usually drizzle or light snow.

Anticyclones are thus regions of clear skies and warm sunny weather in summer; at other times of the year cloudy and foggy weather may be more typical. Winter anticyclones produce colder than normal temperatures at the surface, particularly if the skies remain clear. Anticyclones are responsible for periods of little or no rain, and such periods may be prolonged in association with blocking highs.

Cyclone tracks

Cyclone and anticyclone climatology. Migrating cyclones and anticyclones tend to be distributed around certain preferred regions, known as tracks, that emanate from preferred cyclogenetic regions. The contrast between winter and summer can be seen in Figures 16 and 17, which show cyclone tracks for January and July. Favoured cyclogenetic regions in the Northern Hemisphere are found on the lee side of mountains and off the east coasts of continents. Cyclones then track east or southeast before eventually turning northeastward and decaying. The tracks are also displaced farther northward in July, reflecting the more northward position of the polar front in summer. Continental cyclones usually intensify at a rate of 0.5 millibar per hour or less, although more dramatic examples can be found. Marine cyclones, on the other hand, often experience explosive development in excess of one millibar per hour, particularly in winter.

Anticyclones tend to migrate southeastward out of the cold air mass regions and then eastward before decaying or merging with a warm anticyclone, or they form in the wake of extratropical cyclones. These tracks also migrate northward with the warm season. Anticyclone tracks over North America and the surrounding ocean environment for January and July are shown in Figure 25.

In the Southern Hemisphere, where most of the Earth's surface is covered by oceans, the cyclones are distributed fairly uniformly through the various longitudes. Typically, cyclones form initially in latitudes 30° to 40° S and move in a generally southeastward direction, reaching maturity in latitudes around 60°. Thus the Antarctic continent is usually ringed by a number of mature or decaying cyclones, and the belt of ocean from 40° to 60° S is a region of persistent, strong westerly winds that form part of the circulation to the north of the main cyclone centres. These are the "roaring forties," where the westerly winds are interrupted only at intervals by the passage southeastward of developing cyclones.

Anticyclonic development seldom occurs over the southern oceans. Anticyclones thus are transient features of the weather regime in the Southern Hemisphere.

LOCAL WINDS

Scale classes. Organized wind systems occur with dimensions ranging from tens of metres to thousands of kilometres and possess residence times that vary from seconds to weeks. The typical size and/or lifetime of a phenomenon is known as its scale. Since the atmosphere exhibits such a large variety of both spatial and temporal scales, efforts have been made to group various phenomena into scale classes. The class describing the largest and longest-lived of these phenomena is known as the planetary scale. Such phenomena are typically a few thousand kilometres in size and have lifetimes ranging from several days to several weeks. Examples are the semipermanent pressure centres discussed above and certain globe-encircling upper-air waves (see below *Upper-air waves*). Still another class is known as the synoptic scale. Spanning smaller distances, a few hundred to a few thousand kilometres, and possessing shorter lifetimes, a few to several days, this class contains the migrating cyclones and anticyclones that control day-to-day weather changes. Sometimes the planetary and synoptic scales are combined into a single

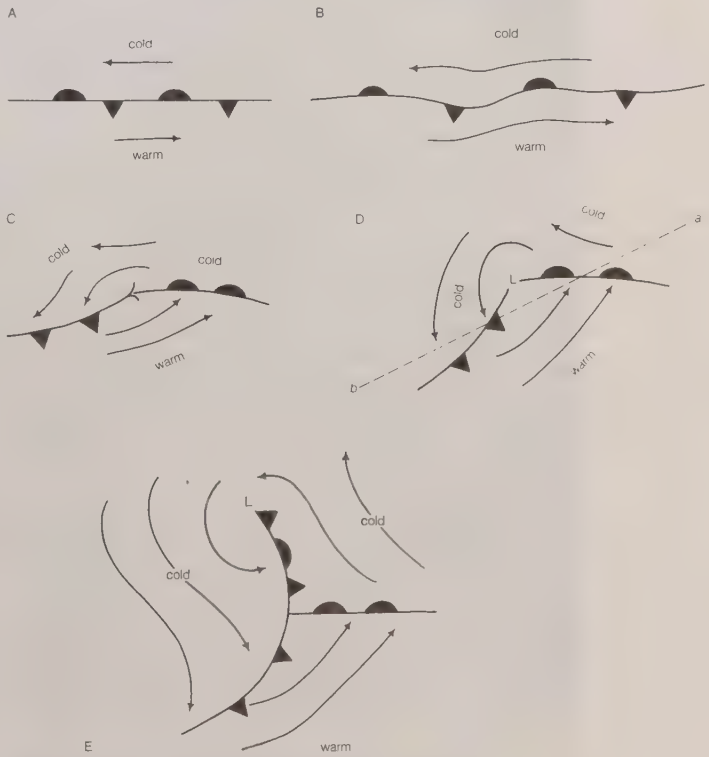

Figure 22: *Evolution of a wave (frontal) cyclone.* Dashed line *ab* in D is the cross-sectional line depicted in Figure 23 (see text).

classification termed the large-scale, or macroscale. Large-scale wind systems are distinguished by the predominance of horizontal motions over vertical motions and by the preeminent importance of the Coriolis force in influencing wind characteristics.

There is a class of phenomena of even smaller size and shorter lifetime, whose vertical motions may be as significant as their horizontal motions and in which the Coriolis force often plays a less important role. Known as the mesoscale, this class is characterized by dimensions of tens to a few hundred kilometres and lifetimes of a day or less. Because of the shorter time scale and because the other forces may be much larger, the effect of the Coriolis force is sometimes neglected.

Two of the best-known examples of mesoscale phenomena are the thunderstorm and its devastating by-product, the tornado (see below *Thunderstorms* and *Tornadoes, whirlwinds, and waterspouts*). The present discussion focuses on less intense, though nevertheless commonly observed, wind systems that are found in rather specific geographic locations and thus are often referred to as local wind systems.

Sea/land breeze

Local wind systems. The first of these is the so-called sea/land breeze. This local wind system is typically encountered along coastlines adjacent to large bodies of water and is induced by differences that occur between the heating or cooling of the water surface and the adjacent land surface. Because water has a higher heat capacity (*i.e.*, more units of heat are required to produce a given temperature change) than do the materials in the land surface, daytime solar radiation heats the land surface more than the water surface. The higher-temperature land surface in turn transfers more heat to its overlying air mass and in so doing induces a circulation cell much like that depicted in Figure 26. It should be noted that the surface flow is from the water toward the land and thus is called a sea breeze. The landmass also cools more rapidly than does the water at night. Consequently, at night the cooler landmass yields a cooler overlying air mass and a circulation cell with air motions opposite to those found during the day (see Figure 26). This flow from land to water is known as a land breeze.

Sea/land breezes occur along the coastal regions of oceans or large lakes in the absence of a strong, large-scale wind system during periods of strong daytime heating or nighttime cooling. Those who live within 10 to 20 kilometres of the coastline will experience the cooler 19- to 37-kilometre-per-hour winds of the sea breeze on a sunny afternoon only to find it turning into a sultry land breeze late at night. One of the features of the sea/land breeze is a region of low-level air convergence in the termination region of the surface flow. Such convergence often induces local upward motions and cloud formations. Thus, in sea/land breeze regions, it is not uncommon to see clouds lying off the coast at night; these clouds are then dissipated by the daytime sea breeze, which forms new clouds, perhaps with precipitation occurring over land in the afternoon.

Another group of local winds is induced by the presence of mountain/valley features on the Earth's surface. One subset of such winds, known as mountain winds or breezes, is induced by differential heating or cooling along mountain slopes. During the day, solar heating of the sunlit slopes causes the overlying air to move upslope. At night, as the slopes cool, the motion is reversed and cool downslope motion occurs. Such winds may be relatively gentle or may occur in strong gusts, depending on the topographic configuration. In an enclosed valley the cool

air that drains into the valley may give rise to a thick fog condition, which persists until daytime heating reverses the circulation and creates clouds ahead of the upslope motion at the mountain top.

Foehn winds

Another subset, called foehn winds (also known as chinook winds east of the Rocky Mountains or a Santa Ana in southern California), is induced by adiabatic temperature changes as air flows over a mountain. Adiabatic temperature changes are those that occur without the addition or subtraction of heat; they occur in the atmosphere when bundles of air are moved vertically. When air is lifted, it enters a region of lower pressure and expands. This expansion is accompanied by a reduction of temperature (adiabatic cooling). When air subsides, it contracts and experiences adiabatic warming. As air ascends on the windward side of the mountain, its cooling rate may be moderated by the heat that is released during the formation of precipitation. However, having lost much of its moisture, the descending air on the leeward side warms up adiabatically faster than it is cooled on the windward ascent. Thus, the effect of this wind, if it reaches the surface, is to produce warm, dry conditions. Usually such winds are gentle and produce a slow warming. On occasion, however, they may exceed 185 kilometres per hour and/or produce temperature increases of tens of degrees within only a few hours.

Still another local wind condition induced by terrain features is the katabatic wind. In this case the geography is characterized by a cold plateau adjacent to a relatively warm region of lower elevation. Such conditions are satisfied in areas in which major ice sheets or cold, elevated land surfaces border warmer, large bodies of water. Air over the cold plateau cools and forms a large dome of cold, dense air. Unless held back by background wind conditions, this cold air will spill over into the lower elevations with speeds that vary from gentle (a few kilometres per hour) to intense (93 to 185 kilometres per hour), depending on the incline of the slope of the terrain and the distribution of the background pressure field. Two special varieties of katabatic wind are well known in Europe. One is the bora, which blows from the highlands of Croatia, Bosnia and Hercegovina, and Montenegro to the Adriatic Sea; the other is the mistral, which blows out of central and southern France to the Mediterranean Sea.

ZONAL SURFACE WINDS

Figures 16 and 17 reveal that on the average certain geographic locations can expect to experience winds that emanate from one prevailing direction largely dictated by the presence of major semipermanent pressure systems. Such prevailing winds have long been known in marine environments because of their influence on the great sailing ships.

Tropical and subtropical regions are characterized by a general band of low pressure lying near the Equator bounded by centres of high pressure that may extend poleward into the middle latitudes. Between these low- and high-pressure regions is the region of the tropical winds. Of these, the most extensive are the trade winds. So named because of their favourable influence on trade ships traveling across the subtropical North Atlantic, these winds flow westward and somewhat in the direction of the Equator on the equatorward side of the subtropical high-pressure centres. The "root of the trades" at the eastern side of the high centre is characterized by subsiding air. This produces the very warm, dry conditions with abundant sunshine found in the eastern extremes of the subtropical Atlantic and Pacific ocean basins. As the trade winds progress westward, however, subsidence abates, the air mass becomes more humid, and scattered showers appear, particularly on islands with elevated terrain features that interrupt the flow of the warm, moist air. The equatorward flow of the trade winds of the Northern and Southern hemispheres often results in a convergence of

Trade winds

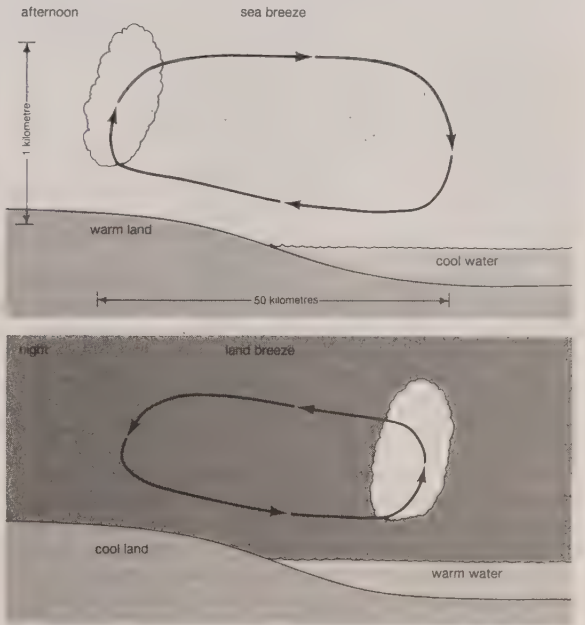

Figure 26: Typical sea-breeze (afternoon) and land-breeze (night) circulations with associated cloud formations.

the two air streams in a region known as the intertropical convergence zone (ITCZ; see Figure 34). Deep convective clouds, showers, and thunderstorms occur along the ITCZ.

When the air reaches the western extreme of the high, it turns poleward and then eventually returns eastward in the middle latitudes. The poleward-moving air is now warm, moist maritime tropical air, and it gives rise to the warm, humid, showery climate characteristic of the Caribbean region, eastern South America, and the western Pacific island chains. The westerlies are associated with the changeable weather common to the middle latitudes. Migrating extratropical cyclones and anticyclones associated with contrasting warm, moist air moving poleward from the tropics and cold, dry air moving equatorward from polar latitudes yield periods of rain, sometimes with violent thunderstorms, snow, sleet, or freezing rain interrupted by periods of dry, sunny, and sometimes bitterly cold conditions. Furthermore, these patterns are seasonally dependent, with more intense cyclones and colder air prevailing in winter but with a higher incidence of thunderstorms common in spring and summer. In addition, these migrations and the associated climate are complicated by the presence of landmasses and major mountain features, particularly in the Northern Hemisphere.

The mid-latitude westerlies

The westerlies lie on the equatorward side of the semipermanent, subpolar centres of low pressure. Poleward of these centres the surface winds turn westward again over significant portions of the subpolar latitudes. As in the middle latitudes, the presence of major landmasses, notably in the Northern Hemisphere, results in significant variations in these polar easterlies. In addition, the wind systems and the associated climate are seasonally dependent. During the short summer season, the wind systems of the polar latitudes are greatly weakened. During the long winter months, these systems strengthen and alternate periods of snow with long intervals of dry, cold air characteristic of continental polar or continental arctic air masses.

These major regions of surface circulation and their associated pressure fields are related to mean meridional circulation patterns as well (see Figure 33). Although their presence is discernible in long-term mean statistics accumulated over a hemisphere, such cells are often difficult to detect on a daily basis at any given longitude.

(P.J.S.)

MONSOONS

A close examination of Figures 16 and 17 reveals particularly strong seasonal pressure variations over continents. Such seasonal fluctuations, commonly called monsoons, are more pronounced over land surfaces because these surfaces are subject to more significant seasonal temperature variations.

Monsoons blow for approximately six months from the northeast and six months from the southwest, principally in southern Asia and parts of Africa. Summer monsoons have a dominant westerly component and a strong tendency to converge, rise, and produce rain. Winter monsoons have a dominant easterly component and a strong tendency to diverge, subside, and cause drought. Both are the result of differences in annual temperature trends over land and sea.

The Indian monsoon. At the Equator, the area near India is unique in that dominant or frequent westerly winds occur at the surface almost constantly throughout the year; the surface easterlies reach only to 20° N in February, and even then they have a very strong northerly component. They soon retreat northward, and drastic changes take place in the upper-air circulation. This is a time of transition between the end of one monsoon and the beginning of the next. Late in March the high-sun season reaches the Equator and moves farther north. With it go atmospheric instability, convectional (rising, turbulent) clouds, and rain. The westerly subtropical jet stream (see below) still controls the flow of air across northern India and the surface winds are northeasterlies. As the high-sun season moves northward during April, India becomes particularly prone to rapid heating because the highlands to the north protect it from any incursions of cold air. In May the southwesterly monsoon is well established over Sri Lanka. There are three distinct regions of relative upper tropospheric warmth—namely (1) above the southern Bay of Bengal, (2) above the highlands of Tibet, and (3) across the still, dry trunks of the peninsulas. The relatively warm area above the southern Bay of Bengal occurs mostly at the 500–100 millibar level. It does not appear at a lower level and is probably caused by the release of condensation heat (associated with the change from water vapour to liquid water) at the top of towering cumulonimbus clouds along the advancing intertropical convergence.

Atmospheric instability and rapid heating

In May the dry surface of Tibet (above 4,000 metres) absorbs and radiates heat that is readily transmitted to the air immediately above. At about 6,000 metres an anticyclonic cell arises, causing a strong easterly flow in the upper troposphere above northern India. The subtropical jet stream suddenly changes its course to the north of the anticyclonic ridge and the highlands, though it may occasionally reappear southward of them for very brief periods. This change of the upper tropospheric circulation above northern India from westerly jet to easterly flow coincides with a reversal of the vertical temperature and pressure gradients between 600 and 300 millibars. On many occasions the easterly aloft assumes jet force. It anticipates by a few days the "burst," or onset, of the surface southwesterly monsoon some 1,500 kilometres farther south, with a definite sequential relationship, although the exact cause is not known. Because of India's inverted triangular shape, the land is heated progressively as the Sun moves northward. This accelerated spread of heating, combined with the general direction of heat being transported by winds, results in a greater initial monsoonal activity over the Arabian Sea (at late spring time), where a real frontal situation often occurs, than over the Bay of Bengal. The relative humidity of coastal districts in the Indian region rises above 70 percent and some rain occurs. Above the heated land the air below 1,500 metres becomes unstable, but it is held down by the overriding easterly flow. This does not prevent frequent thunderstorms in late May.

During June the easterly jet becomes firmly established at 150 to 100 millibars. It reaches its greatest speed at its normal position to the south of the anticyclonic ridge, at about 15° N from China through India.

In Arabia, it decelerates and descends to the middle troposphere (3,000 metres). A stratospheric belt of very cold air, analogous to the one normally found above the intertropical convergence near the Equator, occurs above the anticyclonic ridge, across southern Asia at 30°–40° N and above the 6,000-metre (500-millibar) level. These upper air features that arise so far away from the Equator are associated with the surface monsoon and are absent when there is no monsoonal flow. The position of the easterly jet controls the location of monsoonal rains, which occur ahead and to the left of the strongest winds and behind them to the right. The surface flow, however, is a strong, southwesterly, humid, and unstable wind that brings humidities of more than 80 percent and heavy, squally showers that are the "burst" of the monsoon. The overall pattern of the advance follows a frontal alignment, but local episodes may differ considerably. The amount of rain is variable from year to year and place to place. Most spectacular clouds and rain occur against the Western Ghāts, where the early monsoonal airstream piles up against the steep slopes, then recedes, and piles up again to a greater height. Each time it pushes thicker clouds upward until wind and clouds roll over the barrier and, after a few brief spells of absorption by the dry inland air, cascade toward the interior. The windward slopes receive from 2,000 to 5,000 millimetres of rain in the monsoon season. Various factors, and especially topography, combine to make up a complex regional pattern. Oceanic air flowing toward India below 6,000 metres is deflected in accordance with the Coriolis effect. The converging, moist oncoming stream becomes unstable over the hot land and is subject to convectional turmoil. Towering cumulonimbus clouds rise thousands of metres, producing violent thunderstorms and releasing latent heat in the surrounding air. As a result, the upper tropospheric warm belt migrates northwestward from the ocean to the land. The

Precipitation patterns

main body of air above 9,000 metres maintains a strong easterly flow.

Later, in June and July, the monsoon is strong and well-established to a height of 6,000 metres (less in the far north), with occasional thickening to 9,000 metres (Figure 27, top). Weather conditions are cloudy, warm, and moist all over India. Rainfall varies between 400 and 500 millimetres, but topography introduces some extraordinary differences. On the southern slopes of the Khāsi Hills at only 1,300 metres, where the moist airstreams are lifted and overturned, Cherrapunji has an average rainfall of 2,730 millimetres in July, with record totals of 897 millimetres in 24 hours in July 1915, more than 9,000 millimetres in July 1861, and 16,305 millimetres in the monsoon season of 1899. Over the Ganges Valley the monsoon, deflected by the Himalayan barrier, becomes a

southeasterly air flow. By then the upper tropospheric belt of warmth from condensation has moved above northern India, with an oblique bias. The lowest pressures prevail at the surface.

It is mainly in July and August that waves of low pressure appear in the body of monsoonal air. Fully developed depressions appear once or twice a month. They travel from east to west more or less concurrently with high-level easterly waves and bursts of speed in the easterly jet, causing local strengthening of the low-level monsoonal flow. The rainfall consequently increases and is much more evenly distributed than it was in June (Figure 27, bottom). Some of the deeper depressions become tropical cyclones before they reach the land, and these bring torrential rains and disastrous floods.

Associated dry spells

A totally different development arises when the easterly jet moves farther north than usual because the monsoonal wind rising over the southern slopes of the Himalayas brings heavy rains and local floods. The weather over the central and southern districts, however, becomes suddenly drier and remains so for as long as the abnormal shift lasts. The opposite shift is also possible, with mid-latitude upper air flowing along the south face of the Himalayas and bringing drought to the northern districts. Such dry spells are known as "breaks" of the monsoon. Those affecting the south are similar to those experienced on the Guinea coast during extreme northward shifts of the wind belts (as later discussed), whereas those affecting the north are due to an interaction of the middle and low latitudes. The southwest monsoon over the lower Indus Plain is only 500 metres thick and does not hold enough moisture to bring rain. On the other hand, the upper tropospheric easterlies become stronger and constitute a true easterly jet stream. Western Pakistan, Iran, and Arabia remain dry (probably because of divergence in this jet) and thus become the new source of surface heat.

By August the intensity and duration of sunshine have decreased, temperatures begin to fall, and the surge of southwesterly air diminishes spasmodically almost to a standstill in the northwest. Cherrapunji still receives over 2,000 millimetres of rainfall at this time, however. In September dry, cool, northerly air begins to circle the west side of the highlands and spread over northwestern India. The easterly jet weakens and the upper tropospheric easterlies move much farther south. Because the moist southwesterlies at lower levels are much weaker and variable, they are soon pushed back. The rainfall becomes extremely variable over most of the region, but showers are still frequent in the southeastern areas and over the Bay of Bengal.

By early October variable winds are very frequent everywhere. At the end of the month the entire Indian region is covered by northerly air and the winter monsoon takes shape. The surface flow is deflected by the Coriolis force and becomes a northeasterly flow. This causes an October–December rainy season for the extreme southeast of the Deccan (including the Madras coast) and eastern Sri Lanka, which cannot be explained by topography alone because it extends well out over the sea. Tropical depressions and cyclones are important contributing factors.

Most of India thus begins a sunny, dry, and dusty season. The driest period comes in November in the Punjab; December in Central India, Bengal, and Assam; January in the northern Deccan; and February in the southern Deccan. Conversely, the western slopes of the Karakoram and Himalayas are then reached by the mid-latitude frontal depressions that come from the Atlantic and the Mediterranean. The winter rains they receive, moderate as they are, place them clearly outside the monsoonal realm.

Because crops and water supplies depend entirely on monsoonal rains, it became imperative that quantitative, long-range weather forecasts be available. For a forecast to be released at the beginning of June, it is necessary to use, in April, South American pressure data and Indian upper-wind conditions (positive correlation) and, in May, rainfall in Zimbabwe and Java and easterly winds above Calcutta (negative correlation).

The Malaysian-Australian monsoon. Southeast Asia and northern Australia are combined in one monsoonal system that differs from others because of the peculiar and somewhat symmetrical distribution of landmasses on both sides of the Equator. In this respect, the northwest monsoon of Australia is unique. The substantial masses of water between Asia and Australia have a moderating effect on tropospheric temperatures, weakening the summer monsoon. The many islands (*e.g.,* Philippines and Indonesia) provide an infinite variety of topographic effects. Typhoons that develop within the monsoonal air bring additional complications.

Effects of water areas and topography

It would be possible to exclude North China, Korea, and Japan from the monsoonal domain because their seasonal rhythm follows the normal mid-latitude pattern—a predominant outflow of cold continental air in winter, and frontal depressions and rain alternating with fine, dry anticyclonic weather in the warm season. On the other hand, the seasonal reversal of wind direction in this area is almost as persistent as that in India. The winter winds are much stronger because of the relative proximity of the Siberian anticyclone. The tropical ridge of high pressure is the natural boundary between these nonmonsoonal areas and the monsoonal lands farther south.

The northern limit of the typical monsoon may be set at about latitude 25° N. Farther north, the summer monsoon is not strong enough to overcome the effect of the traveling anticyclones normally typical of the subtropics. As a result, monsoonal rains occur in June and also in late August and September, separated by a mild anticyclonic drought in July. In South China and the Philippines the trade winds prevail in the October–April (winter) period, strengthened by the regional, often gusty, outflow of air from the stationary Siberian anticyclone. Their disappearance and replacement by opposite (southwesterly) winds in the May–September (summer) period is the essence of the monsoon. In any case, these monsoonal streams are quite shallow, about 1,500 metres in winter and 2,000 metres in summer. They bring rain only when subject to considerable cooling, as happens to the windward anywhere on the steep slopes of the Philippines and Taiwan. On the larger islands there are contrasting effects, the slopes facing west receiving most of the rain from May to October and a drought from December to April, whereas the slopes facing east receive orographic rains (those produced when moist air is forced to rise by topography) from September to April and mainly convectional rains from May to October.

Vietnam, Thailand, and Indonesia

In Vietnam and Thailand the summer monsoon is more strongly developed because of the wider expanses of overheated land. The southwesterly stream flows from May to October, reaching a thickness of four to five kilometres; it brings plentiful but not extraordinary rainfall. November to February is the cool, dry season, and March to April the hot, dry one; in the far south the coolness is but relative. Along the east coast and on the eastward slopes more rain is brought by the winter monsoon. In the summer, somewhere between Thailand and Kampuchea in the interior, there may be a faint line of convergence between the southwesterly Indian-Burmese monsoon and the southeasterly Malaysian monsoon.

Monsoonal winds are weak over Indonesia because of the expanses of water and the low latitude, but their seasonal reversal is definite. From April to October the Australian southeasterly air flows, whereas north of the Equator it becomes a southwesterly. It generally maintains its dryness over the islands closer to Australia, but farther north it carries increasing amounts of moisture. The northeasterly flow from Asia, which becomes northwesterly south of the Equator, is laden with moisture when it reaches Indonesia, bringing cloudy and rainy weather between November and May. The wettest months are December in most of Sumatra and January elsewhere, but rainfall patterns are highly localized. In Java, for instance, at sea level alone there are two major regions, an "equatorial" west with no dry season and a "monsoonal" east with extreme drought in August and September.

Australian monsoon

Because of its relatively small size and compact shape, Australia shows relatively simple monsoonal patterns. The north shore is subject to a clear-cut wind reversal between summer (November–April, northwesterly) and win-

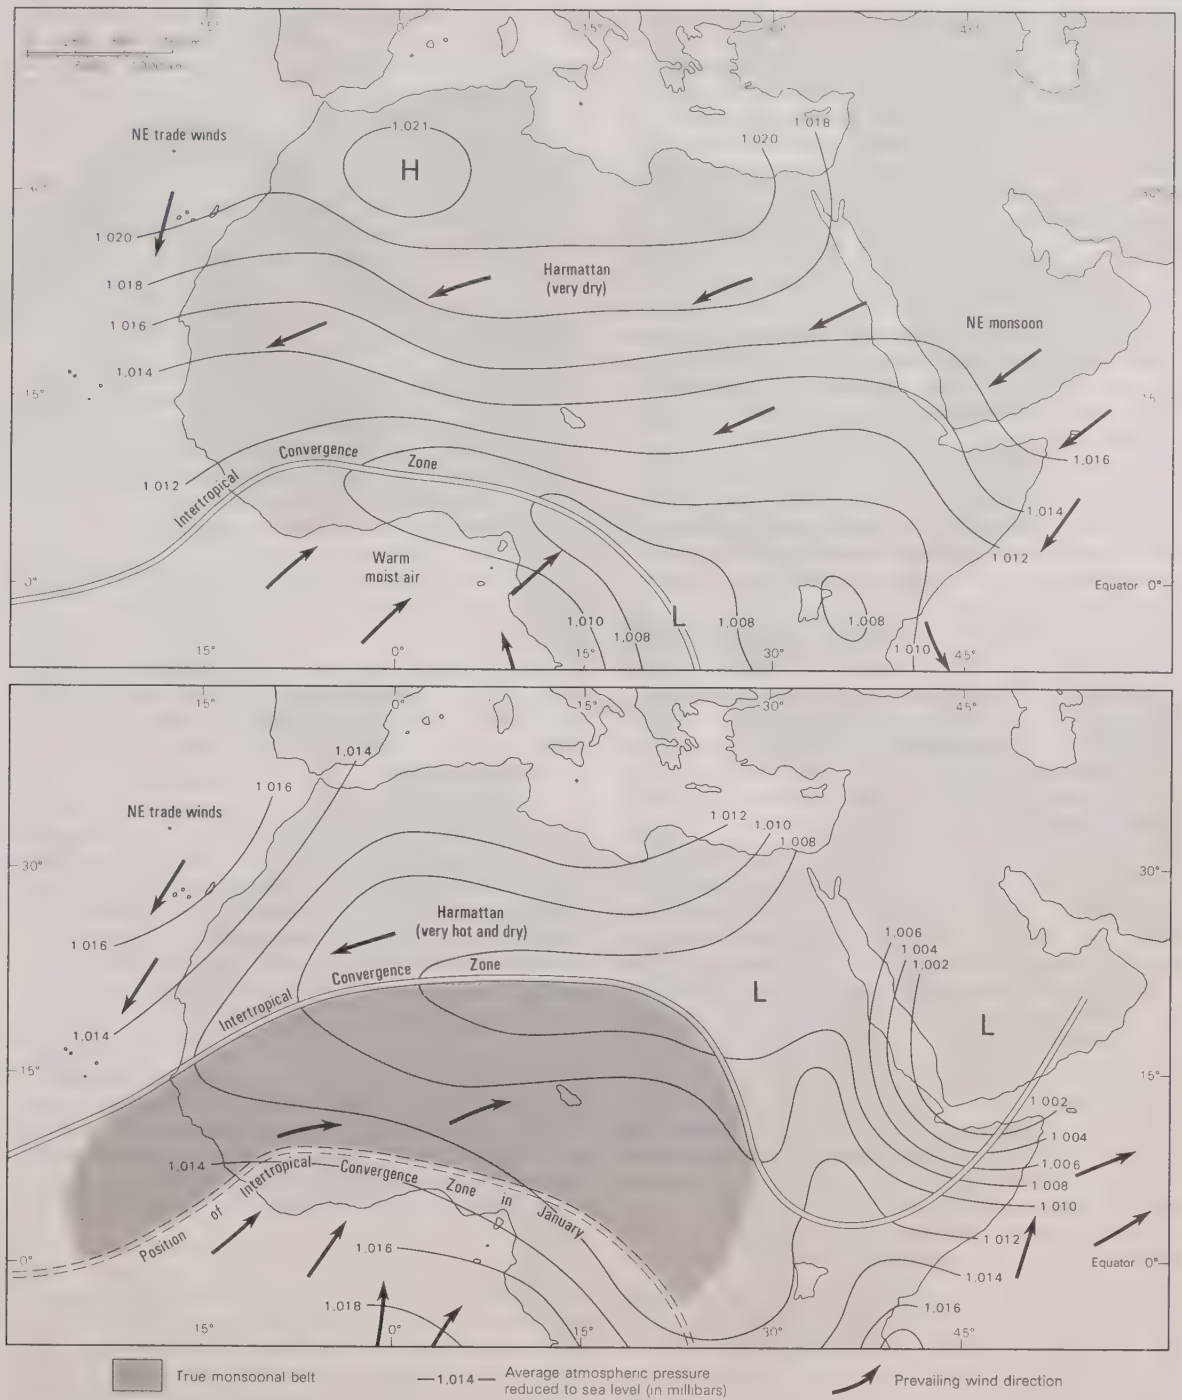

Figure 28: African monsoonal regimes in (top) January and (bottom) July.
From L. Welter and P. Suraud, *Monographie No. 8 de la Meteorologie Nationale* (November 1957)

ter (May–September, southeasterly), but with two definite limitations: first, the northwesterly, rain-bearing monsoonal wind is often held offshore and is most likely to override the land to any depth during January and February; and second, even in summer there often are prolonged spells of southeasterly trade winds issuing from traveling anticyclones, separating the brief monsoonal incursions. The Australian summer monsoon is thus typical in direction and weather type but quite imperfect in frequency and persistence. Its thickness is usually less than 1,500 metres over the sea and 2,000–2,500 metres over the land.

Much less typical are the marginal monsoonal manifestations. On the northwest coast there frequently is a northwesterly air flow in the summer (December–March), as opposed to the winter southeasterlies, but this stream is very shallow and does not bring any rain—*i.e.*, its weather is not monsoonal even though its direction is so. On the northeast coast the onshore air is humid and brings rain, but its direction is only partly modified in summer. It comes in mostly as a northeasterly, while at other times it is mostly southeasterly.

The West African monsoon. The main characteristics of the West African seasons were known over two centuries ago. The southwest winter monsoon flows as a shallow (less than 2,000 metres) humid layer of surface air, overlain by the primary northeast trade wind, which blows from the Sahara and the Sahel as a deep stream of dry, often dusty air. As a surface northeasterly, it is generally known as the harmattan, gusty and dry in the extreme—cool at night and scorchingly hot by day. As in a thorough monsoonal development, upper tropospheric anticyclones occur at about 20° N, while the easterly jet stream may occur at about 10° N, much closer to the Equator than they are in the Indian region.

Alternation with the harmattan

The West African monsoon is the alternation of the southwesterly wind and the harmattan at the surface. As seen in Figure 28, such alternation is normally found between latitudes 9° and 20° N. There are northeasterlies

farther north all the time, but only southwesterlies farther south. The whole year is more or less dry at 20° N except for erratic rains in the high-sun season. The drought becomes shorter and less complete farther south. At 12° N it lasts about half the year, and at 8° N it disappears completely. Farther south a different, lighter drought begins to appear in the high-sun months when the monsoonal southwesterly is strongest. It is due to the arrival of dry surface air issuing from anticyclones formed beyond the Equator in the Southern Hemisphere and is thus similar to the monsoonal drought in Java. Like the "break" of the monsoon in southern India, however, it occurs beyond the Equator.

The moist southwesterly stream, particularly frequent between 5° and 10° N, can reach much farther north, bringing warm, humid nights and moderately hot but still humid days. The harmattan brings cooler nights, but the extreme daily heating causes a thermal range of 10° to 12° C. Even in the daytime, the harmattan may give a sensation of coolness to the human skin as it evaporates moisture from it. The alternation of the two winds is seasonal on the basis of overall frequency, but in fact it varies considerably with the synoptic pressure patterns. The harmattan comes in spells that mostly last from a few days to more than a week.

The advancing fringe of the southwest monsoon is too shallow (under 1,000 metres) for many thunderstorms and disturbances. They usually occur 200–300 kilometres in arrears, where the moist air is deeper (1,000–2,000 metres) but the ground is still hot enough to make it very unstable. The tops of the cumulonimbus may reach 12,000 metres, well above freezing level (4,200–4,500 metres). The disturbances are usually along a given longitude line that is slightly curved and may in fact form one long line squall. They also reach 12,000 metres or more, traveling steadily westward at 37 to 56 kilometres per hour. This suggests that they originate in the primary trade wind aloft and as in India are probably related to the tropical easterly jet stream. The southwest monsoon dominates the weather, and clouds and rain abound. The rain is due primarily to coalescence of droplets, with most of the clouds located below 3,500 metres. The humidity is very high, and the daily range of temperature remains around 4° C.

Seasonal changes

If it were not for the change in wind direction when the southeast trades have crossed the Equator, the monsoon system of West Africa could not be distinguished from the weather system, caused by the seasonal shift in the latitude of the intertropical convergence, as experienced over most of Central Africa. There is a rainy season (in this case, the monsoon season), which on the west coast lasts two to three months at latitude 16° N, three to four months at 14° N, six to seven months at 10° N, and eight months at 8° N.

On the south coast, which is at latitude 4° N to 6° N, the southwest monsoon (as the intertropical convergence) may occur at any time, but the results are quite atypical for various reasons. In the low-sun season (December–February) the southwesterly is rare and ineffective, and the weather is cloudy but dry. From April to June the midday Sun is at its highest, and insolation (radiation received at the Earth's surface) is most intense. Because the southwest wind occurs most frequently, the consequent building up of clouds leads to the main rainy season. During July and August (the short drought) cloudy conditions prevail, but the air issues direct from anticyclones farther south and is dry in spite of the fact that its direction of flow does not change. Although cloudiness decreases after the second high-sun season in September and October, there is a period of occasional rains just sufficient to constitute a secondary maximum.

Toward the north, conditions are more distinctly monsoonal: by latitude 8° N the two wet seasons have merged into one long "wet" with two subdued peaks, which last approximately seven to eight months (March–October). The "dry," which is controlled by northeast winds, lasts from November to early March. There is one rainfall maximum (in August or September) only a short distance farther north, although the wet season is only a few weeks shorter. These changes are shown in Figure 29.

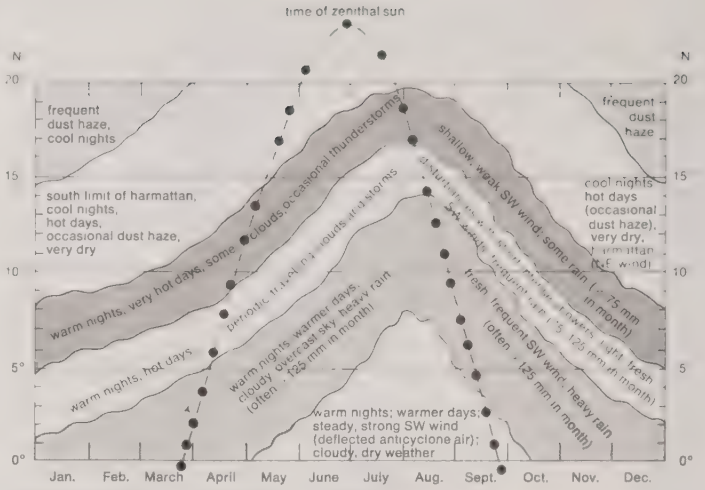

Figure 29: Distribution of climatic characteristics associated with monsoons in West Africa.

Monsoonal tendencies in Europe and North America. In central Europe, where the average wind direction in summer differs some 30° to 40° from that of the Atlantic, there are monsoonal tendencies that occur not as a continuous flow but rather intermittently within frontal depressions, bringing cool, cloudy weather, rain, and thunderstorms. Some see in this climatic pattern a true monsoon, but it is obvious that it is only an "embryo monsoon" that results in weather singularities. The latitude is too high for a true monsoon to arise.

In North America the relatively low latitude and the orientation of the land–sea boundary on the Gulf of Mexico are quite favourable to monsoonal developments. During the summer, low atmospheric pressure is frequent over the heated land; the northeasterly trade winds are consequently deflected to become easterly, southeasterly, or even southerly winds. Texas and the Gulf country generally may be completely overrun by a shallow sheet of oceanic air, which may continue for a long distance inland. The rainfall regime does not reveal any marked monsoonal pattern. There are mostly two, three, or even four minor peaks in the sequence of monthly rainfall totals. In the winter there often occur northers, which are offshore winds caused by the general anticyclonic flow of air from the cold land. Neither the summer onshore wind nor the winter offshore wind is persistent enough to constitute a monsoonal sequence, even though monsoonal tendencies are quite evident.

Central American cycle

In Central America a true monsoonal cycle occurs over a small area facing the Pacific Ocean between 5° and 12° N. Not only is there a complete seasonal reversal of the wind, but the rainfall regime is typically monsoonal. The winter period (from November to January and from March to April according to latitude and other factors) is very dry. The rainy season begins earlier (May) in the south and progressively later farther north, coming at the end of June in southern Mexico. It concludes at the end of September in the north and as late as early November in the south. The result is a rainy season that lasts three months in southern Mexico, increasing in duration with decreasing latitude, to six to seven months in Costa Rica. Latitude for latitude, this is a subdued replica of the monsoon of India. (J.G./P.J.S.)

UPPER-AIR WAVES

Characteristics. Surface pressure and wind systems have already been shown to occur in response to surface heating and cooling, movements of warm and cold air masses, and the presence of various orographic features. Still to be discussed is the role played by pressure and wind systems located well above the surface. Known as upper-air circulations, their most prominent characteristic is the wavelike undulations exhibited in both the pressure and wind fields. These upper-air waves are often coupled with surface cyclones and anticyclones, dictating the severity of the associated weather, the intensity changes of the sur-

face-pressure systems, and the direction of propagation of both the weather and the systems.

Thermal-wind equation

A well-known property of upper-air waves is the presence of winds that are consistently stronger than those found at the surface. This is a consequence of the thermal-wind equation, a relationship between vertical changes in the vector wind and the horizontal temperature gradient. The thermal wind is simply the difference between the vector geostrophic wind at two different levels. The rate of this change per unit of vertical distance is given, for the u and v wind components, by the thermal-wind equation

$$\frac{\partial u}{\partial z} = -\frac{g}{fT}\frac{\partial T}{\partial y} \text{ and } \frac{\partial v}{\partial z} = \frac{g}{fT}\frac{\partial T}{\partial x}, \quad (2)$$

where T is the air temperature; g is the gravitational acceleration (9.8 metres per seconds squared); and $\partial T/\partial x$, $\partial T/\partial y$ are the components of the horizontal temperature gradients in the zonal and meridional directions, respectively. Using the Northern Hemisphere as an example, westerly wind speeds ($u > 0$) will increase with height if air is colder to the north (positive y direction), and southerly wind speeds ($v > 0$) will increase with height if air is colder to the west (negative x direction). Since these are precisely the circumstances often found in the atmosphere, increasing wind speeds with height are the rule. Furthermore, these increases are greatest in regions of strong temperature gradients. Therefore, it is common to find the strongest upper-air winds above low-level fronts.

Another property of upper-air circulations is their geographic displacement with height toward regions of warm or cold air. This so-called tilt of the waves with height is the consequence of an atmospheric property known as hydrostatic balance, and it is easiest to see by focusing attention on the lines of relatively low (trough) and high (ridge) pressure within the wave. This balance is an expression of the fact that a volume of air is subjected to a gravitational force acting toward the Earth's surface which is almost exactly balanced by a pressure force acting vertically in the opposite direction, represented mathematically by

$$g = -\frac{1}{\rho}\frac{\partial p}{\partial z}. \quad (3)$$

Remembering that g is constant, if ρ is larger, $-\partial p/\partial z$ also must be larger. Thus, equation (3) shows that in colder, denser air (larger ρ), pressure decreases more rapidly with height (larger $-\partial p/\partial z$). This leads to several wave-tilt scenarios. First, if at lower levels cold air (larger $-\partial p/\partial z$) is centred in the low-pressure region and warm air (smaller $-\partial p/\partial z$) is centred in the high-pressure region, the two regions will exhibit greater pressure differences at higher levels. Thus, the meteorologist says that "cold-core" lows and "warm-core" highs become more intense with increasing height. Such systems are often slow-moving circulations that influence local weather for several days. For example, warm-core highs, which are common in summer and fall, represent deep layers of warm, dry, stable air. Since they are very stable and have no precipitation, these stagnant air masses permit the accumulation of dust and air pollution, which can reach annoying or even hazardous levels. A second scenario is the reverse of the first. In this case, warm-core lows and cold-core highs decrease in intensity with increasing height. The tropical cyclone is an example of a warm-core low.

Cold-core lows and warm-core highs

Because the cold or warm air is centred on the high- or low-pressure region, neither of these first two cases exhibits any tilt with height. A third very important scenario, however, can exhibit marked tilt. This occurs when the cold or warm air is centred between the lower-level pressure regions. In this case, the most rapid decrease of pressure with height occurs in the cold air between the low and high. Thus, the position of the low (or trough) is displaced toward the cold air with increasing height. Similarly, the pressure decreases less rapidly with height in the warm air, and the high (or ridge) is displaced toward the warm air. In general, the cold air is located upstream from the surface low. This results in a typical tilted-wave configuration in which the upper-air troughs and ridges are located upstream from their corresponding low-level features. Since in middle latitudes (where tilted systems are most prominent) the flow is generally west to east, upstream usually means to the west. Such patterns, represented schematically in Figure 30, are typical of the weather-producing circulation systems of the middle and high latitudes.

Propagation and development. The propagation and development of upper-air waves are largely determined by the horizontal transport (referred to as advection) of cold or warm air and a fluid property known as vorticity. The vorticity of interest in the context of this discussion can be defined as the rotational motion experienced by air parcels moving in the horizontal plane. Mathematically, the vorticity of horizontal motions relative to the Earth (relative vorticity) is given by

Advection and vorticity

$$\delta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}. \quad (4)$$

If the rotation imposed by the rotating Earth is added, a quantity known as the absolute vorticity results:

$$\delta_a = \delta + f \quad (5)$$

where f is the Coriolis parameter (see equation [1]). The absolute vorticity is largest in troughs and smallest in ridges. Thus, positive advections (transport of larger values) tend to occur downstream from upper-air troughs. The resulting increasing in vorticity yields an increase in cyclonic circulation (*i.e.*, the circulation associated with cyclones or troughs). As the air in this region attempts to maintain geostrophic balance in the presence of this increased cyclonic circulation, the pressure is forced to decrease. Downstream from upper-air ridges, advections of negative vorticity occur, giving rise to increased anticyclonic circulations and corresponding pressure increases. The coupled decrease of pressure downstream from the trough and increase of pressure downstream from the ridge in an upper-air wave are precisely the combination of pressure changes required to propagate the wave. Thus, upper-air wave propagation can be largely explained by vorticity advection. This propagation is usually in the direction of the general background flow (west to east in middle latitudes) and is generally faster for shorter waves. In some cases, very long waves (several thousand kilometres) are nearly stationary or actually move in a direction opposite to that of the background flow (referred to as a retrograding wave).

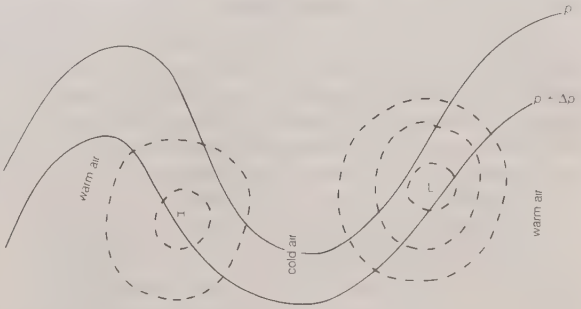

Figure 30: *Middle-latitude tilted-wave pattern.* The pressure field at a height of six kilometres is shown by solid isobars and at sea level by dashed isobars.

The advection of warm or cold air (known as thermal advection) plays quite a different role in upper-air wave behaviour. In order for such advections to occur, the temperature wave must be out of phase with the pressure wave, a so-called baroclinic atmosphere. If the two waves were in phase (barotropic atmosphere), the winds would blow along the isotherms, therefore yielding zero thermal advection. If the two waves are out of phase, it is typical to find the cold air upstream from the trough and the warm air upstream from the ridge, producing cold-air advection in the trough and warm-air advection in the ridge. The resulting colder temperatures in the trough and warmer temperatures in the ridge force a further reduction of

Role of thermal advection

pressure in the trough and increase in the ridge—namely, a wave amplification. Thus, wave development, or amplification, is largely explained by thermal advections and is more likely in strongly baroclinic atmospheres.

Alternately, upper-air wave development has been described as an example of fluid instability. In one theory, originally proposed by the Chinese-American meteorologist Hsiao-lan Kuo in 1949, the waves develop from small disturbances on an atmosphere made unstable by an appropriate horizontal wind shear (barotropic instability), and the energy of the growing wave is drawn from the kinetic energy of the background flow. In another theory, originally published by the American meteorologist Jule G. Charney in 1947, the waves develop in an atmosphere made unstable by an appropriate horizontal temperature gradient (baroclinic instability) and derive their energy from the potential energy of the disturbed atmosphere.

Relationships to surface features. Upper-air circulations play a key role in the development and propagation of surface pressure systems. As noted above, the surface pressure is simply the weight per unit area of the air above the surface. Thus, in order to change the surface pressure, it is necessary to change the mass content of the overriding air. Because large amounts of mass are transferred by upper-air flows, such flows are capable of forcing significant changes in surface pressure.

Generation of surface-pressure changes

The transfer of mass by upper-air circulations occurs in a very nonuniform fashion. As a result, mass tends to build up (mass convergence) in some regions and be depleted (mass divergence) in others. If these convergences or divergences occurred uniformly at all levels above a given surface location, it would be easy to anticipate the resulting surface-pressure changes. Such uniformity, however, is not observed. Rather, divergences in one portion of a column of air are largely compensated by convergences in another. Thus, changes in surface pressure may result from the subtle differences between these conflicting mass divergence/convergence patterns.

Examples of divergence/convergence cross sections for non-tilting and tilting wave systems are presented in Figure 31. Also included are the directions of the vertical air motions required to satisfy mass conservation principles. Such vertical motions are typically very small compared to horizontal motions yet are important because they are largely responsible for the formation or dissipation of clouds. Clouds form in regions of upward motion if sufficient moisture is present and dissipate in those of downward motion. In tilting wave systems, this accounts for the occurrence of inclement weather with low pressure and fair weather with high pressure.

In a non-tilting system, which is characteristic of an occluded cyclone (see above), the bulk of the upper-air divergence and convergence occurs between surface low (L) and high (H) centres, with little happening immediately above the centres. This signifies a propagating wave—a very slow one in some cases—with little intensification of the surface centre. In fact, decay (filling) of the surface centre might occur because of frictionally induced mass convergence in the low and divergence from the high, which is not compensated for by corresponding upper-air mass divergence and convergence. In the tilting system, much of the upper-air divergence and convergence lies above the surface centres. In this case, opportunities are much better for decreasing or increasing the mass above the cyclone or anticyclone, respectively, and thus for intensifying the surface centre. Such a wave also will propagate in the general direction of the mean tropospheric flow.

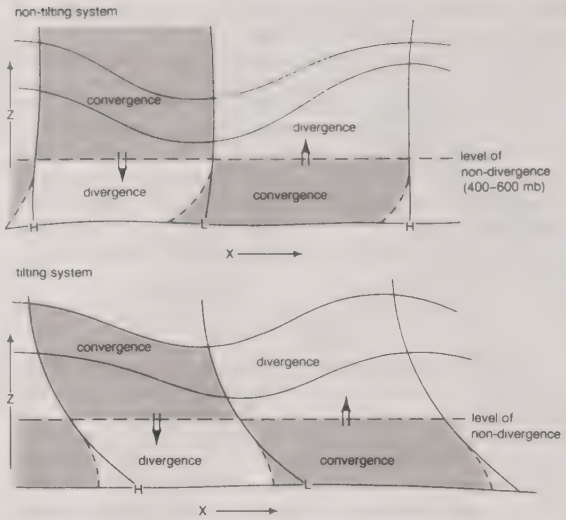

Figure 31: *Vertical cross sections through a wave system depicting typical divergence/convergence distributions for non-tilting and tilting systems.*
Double arrows represent direction of corresponding vertical air motions. X is the horizontal coordinate with arrow pointed in the direction of wave propagation, and Z is the vertical coordinate with arrow pointed upward. L and H are the positions of surface low (cyclone) and high (anticyclone) centres, respectively. The solid lines extending upward from L and H are trough and ridge axes, respectively. The small areas of convergence or divergence near the surface and upstream from the centre positions (dashed lines) are caused by frictional inflow into the low and frictional outflow from the high (see text).

JET STREAMS

Among the more fascinating features of upper-air circulations are discontinuous bands of relatively strong winds (usually in excess of 30 metres per second) called jet streams. As with other wind fields that increase with increasing height, jet streams can be explained as an application of the thermal-wind equation. They are located above areas of particularly strong temperature gradients—*e.g.*, frontal zones. In such areas, the pressure gradients and the resulting wind speeds increase with increasing height so long as the temperature gradients persist in the same direction. In general, this will extend to the tropopause, after which the temperature gradient reverses direction and the wind speeds diminish. Thus, jet streams are usually found in the upper troposphere (*i.e.*, at levels of nine to 18 kilometres).

Because regions of strong temperature gradients can be created in different ways, there are several classes of jet streams. Perhaps the most familiar is the polar-front jet stream. As noted earlier, the polar front is the boundary between polar and mid-latitude air. In winter this boundary may extend equatorward to 30°, while in summer it retreats to 50°–60°. Winter fronts also are distinguished by stronger temperature contrasts than summer fronts. Thus, jet streams are located more equatorward in winter and are more intense during that time. Such streams are generally strongest east of major continents, sometimes exceeding 75 metres per second.

Polar-front jet stream

The polar-front jet is important for several reasons. First, because it is a region of maximum upper-tropospheric flow, it is also one of concentrated upper-air divergence and convergence. Divergence is favoured in the downstream, poleward sector of the jet core as well as in its upstream, equatorward sector (Figure 32). This means that such regions are favoured, though not exclusive, regions for extratropical cyclone development and inclement weather. Second, the polar-front jets, which move west to east but meander with the general upper-air waves, often "steer" the movement of major low-level air masses. This steering is simply a reflection of the very strong mass transport associated with jet streams. Identification of changes in jet-stream flow can often assist in predicting major changes in air mass—hence in temperature and weather—over a

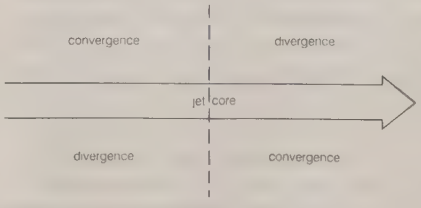

Figure 32: Typical horizontal divergence/convergence patterns associated with a jet stream.

region. Third, jet streams are an important factor in high-altitude flight. Military and civilian jet aircraft depend heavily on reliable information about upper-air winds, which is used for planning the duration of flights and corresponding fuel consumption. Furthermore, jet streams generate a great deal of turbulence because of their strong wind shears. Airlines seek to avoid such "clear-air turbulence" in order to maximize passenger safety and comfort.

Subtropical jet stream

A second jet stream is located at the poleward limit of the equatorial tropical air above the transition zone between tropical and mid-latitude air. This subtropical jet stream is usually found at latitudes 30°to 40°in general westerly flow. This jet may not be marked by pronounced surface temperature contrasts but rather by relatively strong temperature gradients in the mid-troposphere. Moreover, when the polar-front jet penetrates to subtropical latitudes, it may merge with the subtropical jet to form a single band. The subtropical jet, which is generally weaker and located at higher elevations than its higher-latitude cousin, is less commonly associated with migrating cyclones; instead, it may be accompanied by sporadic periods of strong convection, along with heavy rain showers. Also peculiar to the tropical latitudes of the Northern Hemisphere is a high-level jet called the tropical easterly jet stream. Such jets are located about 15° N over continental regions due to the latitudinal heating contrasts over tropical landmasses that are not found over the tropical oceans.

The general location of all three jet streams in relation to other mean meridional circulation features is shown in Figure 33. Jet streams occur in both hemispheres. Those in the Southern Hemisphere resemble the northern hemispheric systems, though they exhibit less day-to-day variability due to the presence of smaller landmasses.

(P.J.S.)

STRATOSPHERIC AND MESOSPHERIC WIND SYSTEMS

The zonal currents and disturbances so far described have their roots and energy sources in the troposphere, the lowest region of the Earth's atmosphere. A second group of wind systems occurs within the overlying stratosphere and mesosphere and extends upward into the ionosphere, where it interacts with the very different systems of the upper atmosphere. The stratosphere and mesosphere are dry, and even the strongest disturbances of the higher level cannot show themselves by means of the clouds so abundant in tropospheric storms. Only at about 25 kilometres does one occasionally see (in winter) small patches of mother-of-pearl cloud. The so-called noctilucent clouds, also rare, occur much higher up—at about 80 kilometres.

Early evidence of stratospheric wind patterns

Before the organization of a worldwide radiosonde network that systematically extended its range above 20 kilometres, it was possible only to infer from acoustic evidence that a unique and different wind regime existed at these levels. It was deduced during the 1930s from the observed travel of the noise of explosions that the winds of the stratosphere apparently reversed annually, in a sort of stratospheric monsoon (though in every other sense this was a misnomer). Below 20 kilometres the basal stratosphere was dominated by the upper parts of the Ferrel westerlies. It was generally believed that the stratosphere above this level was a layer of quiet, undisturbed flow because of the increase of temperature with height.

It is now known—after several decades of additional observation to 35 kilometres and a rather shorter period of rocket-sonde observation to above 60 kilometres—that this impression was false, though the earlier inference of an annual reversal in mid-latitudes has been vindicated.

Polar-night westerlies. Figure 34 sketches the observed circulation. In middle and high latitudes there is indeed a reversing vortex in both hemispheres. In the winter hemisphere the mesospheric westerlies (so called because their

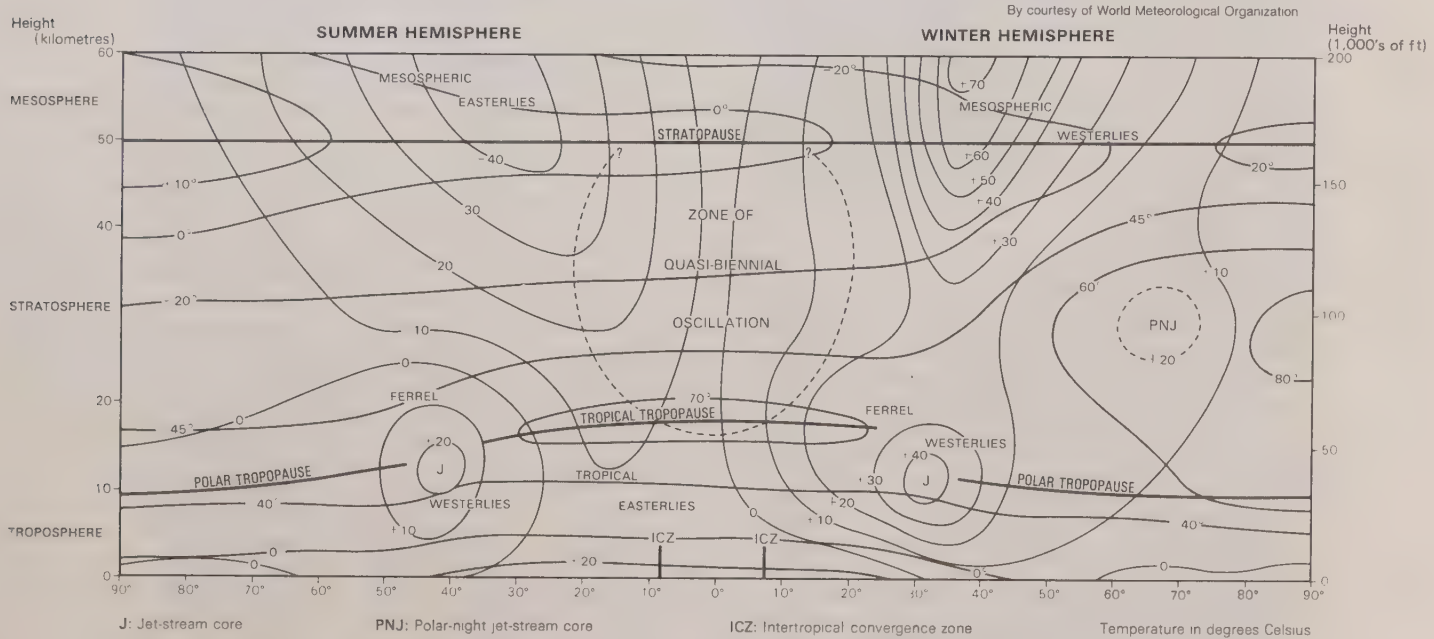

Figure 34: Meridional cross section of the atmosphere to a height of 60 kilometres in summer and winter hemispheres, showing seasonal changes. Numerical values for wind are in units of metres per second and are typical of the Northern Hemisphere, but the structure is much the same in the Southern Hemisphere. Positive and negative signs indicate winds of opposite directional sense (see text).

jet cores lie in the mesosphere) are believed strongest at about 65 kilometres in mid-latitudes, where winds average more than 80 metres per second. In Figure 34 a possible subsidiary-jet maximum near the edge of the polar night is indicated (the polar-night jet). The polar-night area is bitterly cold (down to below −80° C in the 25–35-kilometre layer), and strong westerlies are usually present in the intensely baroclinic zone around this cold core. These westerlies, which are often visible on charts as low as 20 kilometres, have become famous since 1952, when the first explosive warming in them was observed over Berlin. Their relation to the main mesospheric jet is not clear, and they may be distinct.

Deformation by standing waves

The polar-night westerlies of the Northern Hemisphere are deformed by standing waves (mostly of the two-wave sort), with a ridge over and west of Alaska and troughs over eastern Siberia and eastern North America, which are often continuous with similar waves in the Ferrel westerlies below. The southern polar-night system lies over the ocean for much of the winter and is less well known, but it is probably more nearly a pure zonal westerly. Both systems are subject to transient disturbances involving strong vertical motion, as is the whole depth of the mesospheric westerlies. These disturbances show themselves by sudden warmings, sometimes more than 30° C in a day, through substantial depths of the stratosphere. The warmings, once thought to result from some kind of extraterrestrial impulse, are almost certainly due to subsidence on the order of one or two kilometres per day. They temporarily destroy or even reverse the westerly circulation. The last of these warmings brings winter to an abrupt and spectacular end, usually at or before the spring equinox. These invisible events also transfer much ozone downward into the lower stratosphere from the layers of rapid formation higher up, giving the high-latitude belts the curious phenomenon of a spring ozone maximum.

Summer easterlies of the mesosphere and stratosphere. Summer easterlies at high levels, established after some weeks of further vacillation, blow continuously until September (March in the Southern Hemisphere). They are probably strongest at about 70 kilometres in about 50° latitude, where they attain 60 metres per second. As Figure 34 shows, they probably tilt equatorward as one descends, and below 40 kilometres the strongest winds are in about 15° latitude. These easterlies lack the spectacular disturbances of winter but contain rather feeble westward-drifting troughs and ridges.

Between these vast zonal currents, in broadly equatorial latitudes, mean wind speeds are low. In the layer above about 15 kilometres and up to at least 40 kilometres within the 30° parallels, there is a remarkable regime in which the zonal wind reverses on a unique 26-month cycle (the quasi-biennial oscillation), with easterlies giving way to westerlies all around the Earth and then reappearing 26 months later. It has been shown that a 26-month component of variation occurs in many atmospheric phenomena, but in the equatorial stratosphere it dominates the motion of the winds. (F.K.H./P.J.S.)

MAJOR FORMS OF WEATHER DISTURBANCES

The Earth's wind systems, as noted above, are subject to transient but often severe disturbances. In most cases these storms constitute centres of large-scale air ascent. As such, they act as important generators of clouds and precipitation. The principal types of storms include thunderstorms, tornadoes, and hurricanes and typhoons.

Thunderstorms

A thunderstorm is a short-lived storm that is produced by clouds of great vertical extent and that is always accompanied by lightning and thunder. A thunderstorm frequently produces strong, gusty winds, heavy rain, and occasionally hail. Almost invariably, thunderstorms are associated with cumulonimbus clouds, which are dense rain clouds with exceptional vertical development that look like mountains or enormous towers. In an advanced stage, their summits have a smooth, fibrous appearance and occasionally resemble a huge anvil (Figure 35). The base of a cumulonimbus cloud is usually dark because it has great depth. Sometimes, particularly in the mountainous areas of the western United States, water drops from a thunderstorm are small, and they evaporate before reaching the ground as precipitation.

Association with cumulonimbus clouds

VISUAL AND AURAL PHENOMENA

Within a cumulonimbus cloud there are strong updrafts that carry cloud particles and raindrops to the cold upper parts of the clouds. The interaction of water and ice particles causes the separation of electric charge. In general, positive charge is concentrated in the upper regions of the cloud and negative charges near the central regions. When the accumulated electric charge becomes sufficiently large, a lightning discharge occurs. A South African authority, D.J. Malan, has proposed a cloud charge distribution that can schematically represent the distribution in a typical mid-latitude cumulonimbus cloud (Figure 35). A net positive charge is located at an altitude of 10 kilometres (where the temperature is about −45° C) and a net negative charge at five kilometres (−15° C); both charges are of the same magnitude, usually 40 coulombs (an absolute coulomb = 0.1 electromagnetic unit). A smaller positive charge is located at an altitude of two kilometres (+5° C). The electrical potential between the cloud and ground is on the order of 10^8 volts. At this time the charge resides on ice particles or water drops or both. Discharges can occur between any of the oppositely charged regions or between the cloud and the surrounding air.

Cloud-to-ground lightning. The flash of cloud-to-ground lightning is initiated by electrical breakdown between the small positive charge region and the negative charge region. On a time scale measured in fractions of a second, high-speed cameras can record luminous events in the flash (Figure 36). A faint luminous process in regular distinct steps, typically of 50-metre length, at time intervals of 50 microseconds (μsec), descends in a downward branching pattern toward the ground. Carrying currents on the order of hundreds of amperes, this stepped leader or initial stroke propagates at a typical velocity of 1.5×10^5 metres per second, or about one two-thousandth the speed of light. Diameter estimates for the stepped leader range from a few centimetres to a few metres. The current carrying core is on the order of one or two centimetres, and photographic measurements indicate that a sheath of

electric charge (corona sheath) with a diameter of one to 10 metres exists around the core.

As the branching process nears the ground, approximately five coulombs of charge have been deposited on the channel, inducing an opposite charge on the ground and increasing the electric field between the leader and the point to be struck. An upward discharge occurs from the ground, church steeple, house, or other object to meet the stepped leader about 50 metres above the surface. At this moment of junction the cloud is short-circuited to the ground and a highly luminous return stroke of high-current-occurs. Stepped leaders that have not reached the ground become the branches of the return stroke, and charge on the branches flows into the main channel. The five coulombs of charge typically deposited on the stepped leader flow to ground in a few hundred microseconds to produce peak currents that are usually on the order of 20,000 amperes but may range from a few thousand to 200,000 amperes. Temperatures in the channel are on the order of 30,000 K (50,000° F). Due to the junction process occurring near the ground, the time to peak current measured at the ground is typically 10 microseconds. As the charge avalanches toward the ground, the luminosity (return stroke) propagates toward the cloud base at 5×10^7 metres per second, or approximately one-tenth the speed of light, and the high-current-carrying core expands to a diameter of a few centimetres. Laboratory experiments suggest that when pressure equilibrium is attained between the channel and the surrounding air, the channel approximates a high-current arc characterized by a current density of 1,000 amperes per square centimetre.

In the rapid passage from ground to cloud, the luminous return stroke is observed to pause at points where the branches join the main channel (Figure 37), and the channel is observed to brighten as charge from the branch flows into the channel. The stroke then continues its upward propagation, reaching the cloud base in about 70 microseconds; the downward propagating stepped leader traverses the same distance in 20 milliseconds (msec). At this moment there is a pause for tens of milliseconds, and the channel cools to a few thousand kelvins. If a second stroke occurs, it begins with the appearance of a dart of light, perhaps 50 metres in length, propagating down the channel of the return stroke. At a speed of 2×10^6 metres per second (about one one-hundredth the speed of light), the dart leader carries a current on the order of 1,000 amperes toward the ground. Once again a charge centre in the cloud is short-circuited to the ground, and the return stroke occurs. This sequence of dart leader-return stroke typically occurs three to four times, although a flash to the ground that had 26 strokes and lasted two seconds has been reported. When a flash does have more than one stroke, the subsequent return strokes draw charge from successively higher charge centres in the cumulonimbus clouds.

Strokes and energy dissipation

During the return-stroke stage, approximately 10^5 joules of energy per metre are dissipated within the lightning channel. This energy is divided among the dissociation, ionization, excitation, and kinetic energy of the particles, the energy of expansion of the channel, and radiation. Spectroscopic measurements reveal that the air particles, principally nitrogen, oxygen, and water molecules, are split into their respective atoms and that on the average one electron is removed from each atom. The conversion from air molecules to a singly ionized plasma occurs in a few microseconds. At this time the temperature of the plasma is at least 30,000 K and the pressure is greater than 1,000 kilopascals (10 atmospheres). The high pressure greatly exceeds the ambient (surrounding) pressure. The return-stroke channel expands at a supersonic rate, and the shock wave decays to a sound wave that is eventually heard as thunder. Because it is estimated that 1 percent of the input energy is stored in the particles and less than 1 percent emitted as radiation in the visible and infrared region (4,000 to 11,000 angstroms [Å], where $Å = 10^{-8}$ centimetre), it is probable that most of the energy dissipated goes into the energy of channel expansion, a process requiring no more than 10 to 20 microseconds.

A small percentage of discharges between the cloud and ground are actually initiated at the ground and propagate upward to a charged region in the cloud. These discharges often are initiated (or triggered) by tall structures or by

towers on hilltops (Figure 38, top right). The upward branching of such discharges makes them visually distinguishable from their "right-side-up" counterparts, giving the impression of a cloud-to-ground lightning flash that is upside down.

Some physical properties of cloud-to-ground lightning are summarized in Table 3.

Occurrence, duration, and current flow of intracloud lightning

Cloud-to-cloud and intracloud lightning. True cloud-to-cloud lightning is rare because most lightning flashes occur within a cloud. The first lightning flash in a thundercloud is typically an intracloud discharge. When an intracloud discharge occurs, the cloud becomes luminous for approximately 0.2 second. The discharge is initiated by a leader that propagates between charge centres. The 0.2-second illuminosity is continuous and has several pulses of higher luminosity of one-millisecond duration superimposed upon it. This situation suggests minor return strokes as the leader contacts pockets of charge, but the similarity ends there. During the 0.2 second, the amount of the charge transfer is probably similar to the amount involved in a ground discharge: 20 coulombs, with a range from 0.3 to 100 coulombs. The mean velocity of propagation of the intracloud flash is 1×10^4 to 2×10^4 metres per second. Electric currents associated with the luminous brightening are probably in the range of 1,000 to 4,000 amperes. Strikes to aircraft indicate peak currents of only a few thousand amperes, an order of magnitude less than currents in ground flashes. Rise times to peak currents are measured in milliseconds, three orders slower than rise times in return strokes. The energy of intracloud flashes is unknown.

Thunder. When air is crossed by a spark or a lightning flash, the air is heated rapidly and the cylindrical column expands at supersonic speed. Within a metre or two the shock wave decays to a sound wave. The sound heard as thunder comes from the entire channel length and is modified by the intervening medium. The result is a series of sounds that are variously described as peals, claps, rolls, and rumbles. These can conveniently be condensed into claps, which are sudden loud sounds, and rumbles, which are all other sounds of thunder. At short distances of a few hundred metres, the thunder begins with a sudden clap followed by a long rumble. At extended distances the thunder begins with a rumble. Because light travels at 299,300 kilometres per second and sound travels at about

335 metres per second, observation of the time of arrival of thunder permits calculation of the distance to the flash; the sound will travel 1.6 kilometres in five seconds. For close lightning the elapsed time until the beginning of the thunderclap gives the minimum distance to the flash, and the time duration to the rumble is a minimum estimate of the channel length. A thunderclap heard two seconds after the flash, followed by a rumble of 20 seconds, for example, indicates a distance to the flash of approximately 610 metres and a channel length at least 6.4 kilometres. For reasons that include the atmospheric temperature lapse rate, wind shear, and terrain features, thunder is rarely heard at distances greater than 24 kilometres. The energy spectrum of thunder has been recorded and shows that most of the energy is in the low-frequency audible range with a maximum at 50 hertz (cycles per second).

(R.E.Or./L.J.B./Ed.)

CAUSES OF THUNDERSTORMS

Instability and convection

Thunderstorms occur when the atmosphere exhibits instability. In essence, when a weather system is unstable, a small displacement leads to a larger one. When the atmosphere is unstable, a volume of air having an upward displacement for any reason will continue moving upward at an accelerating rate. If a sufficiently large mass of air begins rising, an updraft will result. If the air is moist as well as unstable, a cloud will form. Further growth can lead to precipitation and lightning.

The atmosphere becomes unstable when the temperature decreases rapidly with height, this change resulting most often from solar heating of the Earth's surface and of the air in the lowest layers of the atmosphere. Some of the heat is transported upward by means of molecular motion and small-scale turbulent eddies of air. If the incoming energy exceeds that being transported upward, the temperatures in the lowest layers rise, causing the temperature lapse rate (the rate of temperature decrease with height) to increase. When the lapse rate exceeds certain specific values depending on the humidity properties of the air, the atmosphere becomes unstable. If upward air motion is initiated by a mountain ridge, for example, a rising convection current is set in motion. The ascending stream of air will be warmer and more buoyant than the surrounding air. Heat and moisture are carried upward. Countercurrents transport cooler and drier air downward. The associated puffy clouds that start as cumulus and may become cumulonimbus are called convective clouds.

Such clouds may be initiated in a variety of ways. Some early studies indicated that convective clouds and thunderstorms were initiated as a result of excessive warming of certain surface areas. The temperature differences were attributed to differences in the colour and hence the absorption properties of various soils and rocks. Sometimes thermals may be traced to such hot spots, but evidence indicates that most thunderstorms are set off as a result of organized lifting of the air.

As noted previously, mountain ridges are important in generating thunderstorms. Not only do the ridges serve as a barrier that forces the air to rise but they also become what are sometimes called high-level heat sources. Solar heating of the high terrain causes the air close to them to be warmer than the air at the same altitudes over the adjacent valleys. Because the warm air is less dense, it rises through the surrounding cooler and heavier air. The importance of this effect is shown by the fact that, even in mountainous areas, most thunderstorms occur during the afternoon and early evening hours when it is warmest.

Thunderstorms are often initiated when a cold front advances toward moist, unstable air (see above), which is forced to rise over the frontal surface. Sometimes lines of thunderstorms occur above and nearly parallel to a cold frontal surface. More often, particularly over the central United States, long lines or zones of thunderstorms develop in the warm air many tens of kilometres, sometimes several hundred kilometres, ahead of the cold front. The tendency of these so-called prefrontal squall lines to be more or less parallel to the front has suggested that they have been initiated by a dynamic mechanism related to the front.

Prefrontal squall lines

In the tropics, weather fronts of the kinds so commonly noted at higher latitudes are almost never observed. Air masses of contrasting temperature do not come into contact, as is the case at the polar front, when air from the polar regions encounters air from the tropics. Nevertheless, the regions of maximum thunderstorm frequency occur in equatorial and tropical regions (Figure 39). These storms are triggered by air rising as a result of converging wind systems. When the northeast trade winds meet the

By courtesy of the World Meteorological Organization

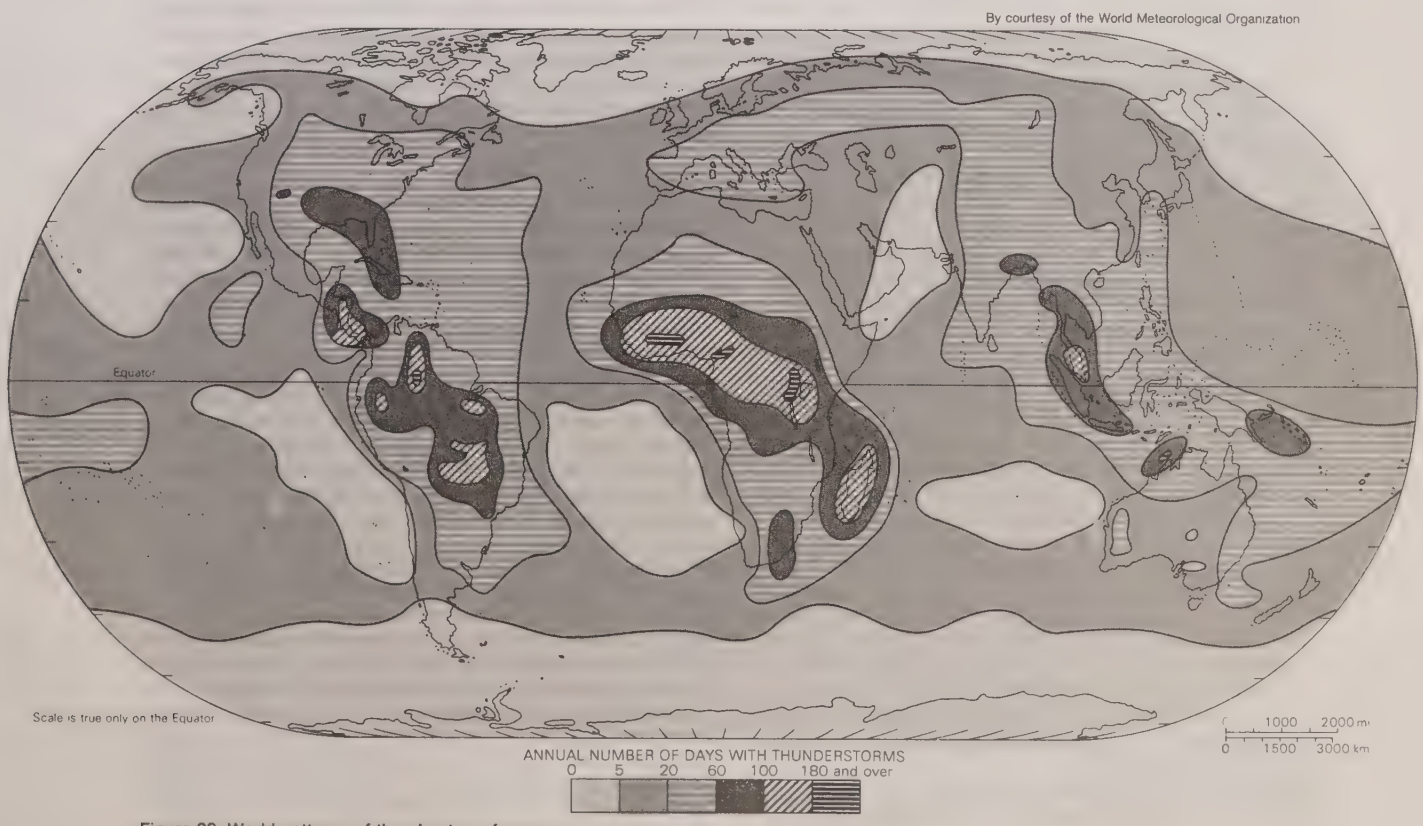

Figure 39: World patterns of thunderstorm frequency.

southeast trades, the air at the zone of confrontation must rise. Because it is both moist and unstable, showers and thunderstorms are produced in abundance.

Disturbances in the low-altitude wind field may lead to convergence and ascending air. Such disturbances occur often both in equatorial areas and at higher latitudes and give rise to cumulonimbus clouds and thunderstorms.

TYPES OF THUNDERSTORMS

At one time it was common to classify thunderstorms according to where they occurred; for example, as airmass, frontal, or orographic (mountain-related) thunderstorms. Since the early 1960s, it has been found more meaningful to classify them according to the chief characteristics of the storms themselves. Such characteristics depend largely on the properties of the environment in which a given thunderstorm develops.

Isolated thunderstorms, especially those that occur under atmospheric conditions such that the wind velocity does not change markedly with height, are sometimes called air-mass, or local, thunderstorms. They are mostly vertical in structure, relatively short-lived, and usually do not produce violent weather at the ground level. Extensive flight measurements indicate that such thunderstorms are composed of one or more individual cells, each of which passes through a definable life cycle. Early in the growth of the cloud, air motions are mostly upward not as a steady, uniform stream but as one that is composed of a series of rising eddies. The precipitation particles grow as the cloud grows; when the accumulated water and ice becomes excessive, a downdraft is started. At maturity a local storm may be composed of intense updrafts and downdrafts side by side (Figure 40). In its later stages the updraft spreads throughout the cell and diminishes in intensity as the precipitation falls out.

Organized storms

Violent weather at ground level usually results from a type of thunderstorm that is sometimes referred to as an organized storm. Over the central United States, it commonly occurs when the winds in the middle layer of the atmosphere are from the southwesterly quadrant and are strong. Although there is still considerable debate about the structure of such storms, many authorities are convinced that in such thunderstorms the updraft is tilted from the vertical. Storms of this sort may last for many hours, remaining in a constant state of regeneration because moist, unstable air is drawn into the lower part of the cloud. Long swaths of hail can be produced by these storms. Strong, gusty winds are very common, and tornadoes sometimes are generated.

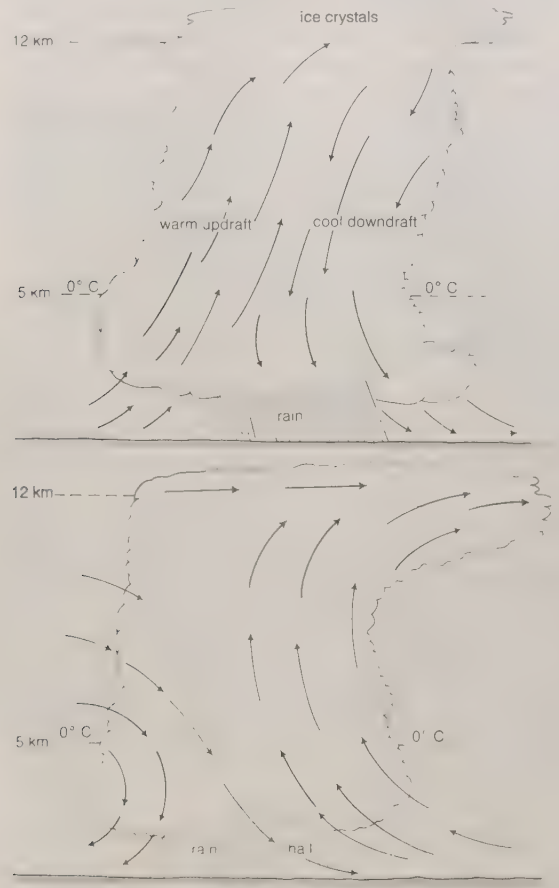

Figure 40: *Thunderstorm models.*
(Top) Mature stage of an isolated thunderstorm cell.
(Bottom) Cross section through a hail-producing organized thunderstorm.

ENERGY OF THUNDERSTORMS

The energy to drive thunderstorms is supplied by a variety of sources, but most of it comes from the heat released when water vapour condenses to form cloud droplets. For every gram of water condensed, about 600 calories of heat are made available. When the water freezes in the upper parts of the cloud, another 80 calories of heat per gram of water are released. This energy goes to increase the temperature of the updraft and, in part, is converted to kinetic energy of upward and downward air movement. If the quantity of water that is condensed in and subsequently precipitated from a cloud is known, then the total energy of a thunderstorm can be calculated. In an average thunderstorm, the energy released amounts to about 10^7 kilowatt-hours, which is equivalent to a 20-kiloton nuclear warhead. A large, severe thunderstorm might be 10 to 100 times more energetic.

PHYSICAL CHARACTERISTICS

An individual thunderstorm cell may be three kilometres in diameter, extend to an altitude of eight to 10 kilometres, and last less than 30 minutes. A larger local thunderstorm would be composed of many cells in different stages in their life history. Such a storm can be tens of kilometres in diameter, its summit may extend to altitudes exceeding 18 kilometres, and its duration may be many hours.

When referring to the diameter of a thunderstorm, it is necessary to specify what is being measured. The quantities cited above refer to the diameter of the cloud at middle altitudes, the distance observed by an airplane flying through the cloud at an altitude of perhaps five kilometres. In such a penetration, the aircraft might encounter several updrafts and downdrafts. The most extensive measurements of thunderstorm properties by means of airplanes were made by the Thunderstorm Project conducted in 1946 and 1947 by the U.S. Weather Bureau in collaboration with the U.S. Navy and Army air forces.

Updrafts and downdrafts. Although updrafts and downdrafts encountered in Ohio and Florida thunderstorms sometimes had diameters exceeding four kilometres, most often they were between about 500 and 2,500 metres at altitudes from three to eight kilometres. At flight levels near 1,500 metres, the drafts tended to have a greater diameter and be weaker than at greater heights in the clouds.

Measured updraft speeds

Updraft speeds measured by the Thunderstorm Project ranged to a maximum of 26 metres per second (m/sec) but usually were less than half that much. They increased with height and averaged 5.0, 7.3, and 8.4 m/sec at altitudes of 1.5, 4.5, and 7.6 kilometres, respectively. At the same altitudes, mean downdrafts were 4.6, 6.1, and 7.3 m/sec, respectively. At greater altitudes, higher updraft speeds have been measured by aircraft and radar and have been inferred on theoretical grounds. Updrafts exceeding 20 m/sec are not considered unusual in the upper parts of large thunderstorms. Airplanes flying through them at altitudes about 10 kilometres have measured updrafts exceeding 30 m/sec. The strongest updrafts have been observed in severe organized thunderstorms, which often are many tens of kilometres in diameter. Lines or zones of such storms sometimes extend for many hundreds of kilometres.

Vertical extent of thunderstorms. The heights of thunderstorms have been measured by radar and by aircraft flying over their tops. They commonly extend to altitudes of more than 11 kilometres and sometimes to more than 20 kilometres. On very unstable days when the atmosphere is moist, the upper limit of the thunderstorm cloud

is determined by the depth of the troposphere, that region of the atmosphere lying below the stratosphere. On such occasions the rising updraft air would be warmer than its environment until it penetrates through the base of the stratosphere. Since this layer is characterized by air temperatures that are nearly constant or may increase with height, it has great stability. The momentum of an updraft would carry it into the stratosphere, but after a short penetration the rising air would be cooler and heavier than the surrounding air. The resulting downward force would stop further upward motion.

The base of the stratosphere varies with both latitude and season of the year. In general, it ranges from about 10 to 20 kilometres with the higher found in the summer at lower latitudes. When the rising air of the cloud encounters the stable stratosphere, it spreads outward and forms the anvil cloud so characteristic of thunderstorms (see above Figure 11, top centre). If winds are light, the anvil may extend in all directions around the cloud. Most of the winds at the anvil altitudes carry cloud material downwind.

Thunderstorm tops do not usually reach the stratosphere. More often their vertical extent is determined by a stable layer in the troposphere. For a number of reasons, layers may be formed where the temperature is constant or increases with height. Sometimes the air temperature decreases only slowly with height. Regions where the temperature decreases slowly or increases with height are stable layers, and a rising volume of air encountering them often cannot penetrate them. As a result, the stable layer determines the maximum vertical extent of the cloud and the altitude where the cloud spreads out to form the anvil.

Turbulence. An airplane flying through a thunderstorm is commonly carried upward and downward by the drafts in the storm. In addition, it often is buffeted from side to side and up and down. This motion is called turbulence, which is caused by large changes in air motions over distances comparable to the dimensions of the airplane. Turbulence not only causes discomfort for the crew and passengers but also subjects the aircraft to undesirable stresses.

Turbulence may be expressed in various units. Commonly, the g unit, equal to the acceleration of gravity of the Earth, is used. A gust of 1 g will cause severe aircraft turbulence. In the upper part of violent thunderstorms, vertical accelerations of about 3 g have been reported.

Movement of thunderstorms. The motion of a thunderstorm is determined largely by the average wind velocity in the layer of the atmosphere in which the storm develops. The average speed of 120 thunderstorms observed in Florida and Ohio in the United States was 20 kilometres per hour, but some storms moved much faster. In extreme circumstances thunderstorms may move at 65 to 80 kilometres per hour.

When considering the movement of a thunderstorm, the storm's dynamic character must be taken into account. Most storms are in a constant state of change, with new cells developing while old ones dissipate. When wind speeds are light, an individual cell may move very little, less than two kilometres, during its lifetime; however, new cells forming downwind may give the illusion of rapid cloud motion. This type of behaviour is often observed in mountainous areas. The first storms of the day generally form over the ridges. As the day progresses, new clouds develop near the existing ones but closer to the valleys. An observer who sees the nearest edge of the clouds coming closer may readily assume that the original clouds are moving over the valley.

Although new cloud developments generally occur downwind of an existing storm, this is not necessarily the case. Sometimes they grow on the flanks, and, as a result, visual observations may lead to the notion that there is little relation between the winds and thunderstorm motion. As would be expected, this view is most likely to arise when wind speeds are low.

WEATHER UNDER THUNDERSTORMS

The air in a thunderstorm downdraft descends from altitudes where the temperature is lower than at the ground. Moreover, the downdraft is maintained at a cooler temperature than its environment by the evaporation of water and ice particles. The sinking air is not only heavier than the surrounding air but its so-called horizontal momentum also differs from that of the surrounding air. If the descending air originated at an altitude of 10 kilometres, for example, it would reach the ground with a horizontal velocity that somewhat resembles the wind velocity at its level of origin. When the air strikes the ground, it usually moves outward ahead of the storm at a higher speed than the speed of the storm itself.

Wind velocities and temperature

In extreme circumstances, the outrushing, cool air may reach velocities of 100 kilometres per hour or more and do extensive damage to property and vegetation. This severe wind most often occurs when organized lines of severe thunderstorms form in an environment where the middle level winds are very strong. When serious wind damage is produced by such a storm, the victims may suspect that it was caused by a tornado. Of course, if a funnel cloud is observed, then the nature of a storm would be obvious. If a funnel cloud is not observed, the character of the damage can be revealing. Tornadoes blow debris in a tight circular pattern, whereas the outflowing air from a thunderstorm pushes it mostly in one direction.

An observer on the ground watching a thunderstorm approach can feel the gusty, cool air before the storm passes overhead. The outspreading, downdraft air forms a pool some 500 to 2,000 metres deep. Often there is a very distinct boundary between the cool air and the warm, humid air in which the storm formed in the first place. The passage of such a boundary is easily recognized as wind speeds increase and the air temperature suddenly drops. Over a five-minute period, a cooling of more than 5° C is not unusual, and cooling that is twice as great is not unknown.

Precipitation from storms

By the time the cool air begins spreading over the ground, rain usually is reaching the surface. Sometimes all the raindrops evaporate while falling, and the result is a dry thunderstorm. At the other extreme, thunderstorms can produce torrential rain and hail. Under a cumulonimbus cloud, impending rain usually can be predicted when the cloud base darkens, indicating a deep layer of cloud obscuring the rays from the Sun. Often, but not usually, a flash of lightning occurs and the precipitation follows several minutes later. There is still disagreement over the interpretation of this sequence of events. Once the precipitation commences, it builds up rapidly, commonly reaching its maximum intensity between five to 10 minutes after the start. In small Ohio thunderstorms, for example, the maximum five-minute rate was 122 millimetres per hour, but most often was less than one-tenth of this amount. The average thunderstorm yielded 2×10^8 kilograms (220,000 short tons) of rain, but some large storms produced 10 times more. Large organized storms can generate 10^{10} to 10^{12} kilograms of rain.

Table 4 lists certain extreme rainfall quantities in various parts of the world. They represent measurements at a single point. As the duration of the rainfall increased, the average rates decreased but were extreme in every case shown. Such rapid accumulations of water invariably cause flooding; greater damage is, of course, associated with longer durations and greater quantities.

OCCURRENCE OF THUNDERSTORMS

Thunderstorms are most likely to occur in a moist, unstable atmosphere. Air masses having these properties are commonly formed over equatorial and tropical areas. When a body of air moves over low-latitude oceans, it is humidified by evaporation from the underlying water surface. Heat is transferred from the warm ocean water to the air. In addition, the nearly direct rays from the Sun warm the moist, lowest layers of the atmosphere. As a consequence of these processes, moist, tropical air masses develop suitable properties for thunderstorm formation.

Disturbances in the wind field caused by pressure perturbations or changes in topography leading to an upward displacement of the air initiate the development of thunderstorms. All the conditions necessary for their occurrence are most often met over the land areas in the equatorial zone between 10 degrees north and south latitudes where

*Probably from thunderstorms, but not documented.

Frequency of storms

the average number of days with thunderstorms exceeds 100 per year. In certain places in equatorial Africa and South America, there are more than 180 days of thunderstorms in an average year (Figure 39).

At higher latitudes, the frequency of thunderstorms depends on the character of the topography and the frequency of invasions of moist, tropical air. Since this happens most often in the spring and summer, the Northern Hemisphere experiences most of its thunderstorms between May and September, whereas thunderstorm maximums are found approximately six months later in the Southern Hemisphere.

Over the large continental area of North America, thunderstorms occasionally occur, even in the winter, in the states along the coast of the Gulf of Mexico. As summer approaches, moist, tropical air gradually extends to higher latitudes and thunderstorms do likewise. By July and August they occur on the average on more than six days per month over the flatlands of central Canada.

During midsummer, areas of high thunderstorm frequency are centred over the Florida peninsula and northern New Mexico where 18 to 20 thunderstorm days per month are experienced. The frequent thunderstorms in the New Mexico–Colorado area are initiated as warm, humid air is forced to rise on the east slope of the Rocky Mountains. On a yearly basis there are about 90 thunderstorm days in central Florida.

Association with summer monsoons

Thunderstorms constitute a common feature of the summer monsoons (see above) in many parts of the world, particularly over southern Asia. As solar radiation warms the continent, an ocean-to-land air current is established. Moist, unstable air from the Indian Ocean is carried inland and is forced to rise up the steep slopes of the Himalayas. As a result, showers and thunderstorms are produced in great abundance. Record high rainfalls occur.

In cold regions, poleward of about 60° latitude, thunderstorms are scarce or nonexistent because of the cold air near the ground and the stable atmospheric conditions. There also are few thunderstorms over those parts of the Earth dominated by semipermanent high-pressure centres. In these regions, which correspond to the great deserts of the world, the air generally descends. This causes a drying of the air and a stabilization of the atmosphere. As a result, thunderstorm development is inhibited.

OBSERVATIONS OF THUNDERSTORMS

Most of the existing data on thunderstorms have been accumulated by weather observers. Unfortunately, by visual observation, it is difficult and often impossible to obtain quantitative information about the characteristics of the clouds that produce the thunder. When widespread thunderstorms occur, the sky commonly is overcast with many intermingled layers of clouds of various types. Cloud summits are frequently obscured.

Advances in aviation, and in particular the development of airplanes of high structural integrity, have made it possible to fly through thunderstorms to measure their internal properties. High-flying airplanes have yielded accurate data on the vertical extent of thunderstorms.

Radar observation of storms

The development of radar during World War II contributed much to scientific knowledge about thunderstorms. Most of the available statistics on thunderstorm dimensions and movements have been obtained by means of radar. Conventional radar sets measure the location and reflectivity of water and ice particle concentrations. By noting changes in the intensity, size, or position of radar echoes, it has been possible to infer the nature of the motions in the thunderstorms.

Networks of radar sets are employed by the civil and military weather services in several countries to detect and track thunderstorms. All commercial airliners are now equipped with radar to allow the pilots to observe thunderstorms and take evasive action and thereby reduce flight hazards and increase passenger comfort.

Since about 1960, atmospheric scientists have used pulsed-Doppler radar sets. Such equipment not only can make the same observations as were made by earlier radars but can measure the instantaneous fields of motion of the precipitation particles. In certain circumstances, this information can be used to measure the speeds of updrafts and downdrafts. Furthermore, it is sometimes possible to infer the size of the precipitation particles.

Weather satellites photograph cloud patterns and telemeter the pictures back to Earth. Radiometers on board the satellites supply information on the temperatures of the clouds that are observed. On the basis of appearance and temperature, it is possible to infer when a cloud is a cumulonimbus and, hence, probably a thunderstorm source. At the present time, satellite data are revealing patterns of convective cloud and thunderstorm development on a scale never seen before. The information has been particularly valuable over the vast, low-latitude oceanic areas that were never adequately observed in the past. (L.J.B./Ed.)

Tornadoes, waterspouts, and whirlwinds

Tornadoes, whirlwinds, and waterspouts are atmospheric vortices, or rotating funnel-cloud air masses of small diameter. They are differentiated from each other by the intensity of their rotation and by the surfaces that they traverse. Though tornadoes and whirlwinds both travel over landmasses, whirlwinds are atmospheric systems smaller than tornadoes. Waterspouts are tornadoes that form or pass over a water surface.

GENERAL CHARACTERISTICS

Tornadoes. The name tornado comes from the Spanish *tronada* ("thunderstorm"), which supposedly was derived from the Latin *tornare* ("to make round by turning"). The most violent of atmospheric storms, a tornado is a powerful vortex, or "twister," whose rotational speeds are estimated to be close to 480 kilometres per hour but may occasionally exceed 800 kilometres per hour. The direction of rotation in the Northern Hemisphere is usually, though not exclusively, counterclockwise.

The first visible indication of tornado development is usually a funnel cloud (Figure 41), which extends downward from the cumulonimbus cloud of a severe thunderstorm (see above). As this funnel dips earthward, it becomes darker because of the debris forced into its intensifying vortex. Some tornadoes give no visible warning until their destruction strikes the unsuspecting victims. Tornadoes often occur in groups, and several twisters sometimes descend from the same cloud base (Figure 41).

Speed of a tornado

The forward speed of an individual tornado is normally 48 to 64 kilometres per hour but may range from nearly zero to 112 kilometres per hour. The direction of motion is usually from the southwest to the northeast, although tornadoes associated with hurricanes may move from the east. The paths of twisters average only several hundred metres in width and 26 kilometres in length, but large deviations from these averages may be expected; *e.g.*, a devastating tornado that killed 689 persons in Missouri, Illinois, and Indiana in the midwestern United States on March 18, 1925, was at times 1.6 kilometres wide, and its path extended 352 kilometres.

In the short time that it takes to pass, a tornado causes fantastic destruction. There have been cases reported in which blades of straw were embedded in fence posts; a schoolhouse with 85 pupils inside was demolished and the pupils carried 137 metres with none killed; and five railway coaches, each weighing 70 tons, were lifted from their track and one coach was moved 24 metres.

Figure 41: *Tornadoes of the midwestern United States.*
(Left) A typical killer tornado photographed in Tracy, Minn., on June 13, 1968; it traveled 21 kilometres along the ground. (Right) Twin funnels, in one of the worst recorded tornado outbreaks, crossing a highway south of Elkhart, northern Indiana, on April 11, 1965; debris can be seen falling out of the left funnel.
(Left) Eric Lantz, (right) Paul Huffman

Although much remains to be learned about tornado formation and movement, remarkable advances have been made in the effectiveness of tornado detection and warning systems. These systems involve analyses of surface and upper-air weather, detection and tracking of atmosphere changes by radar, and spotting severe local storms.

Waterspouts. When a tornado forms or passes over a water surface, it is termed a waterspout. Like tornadoes, they may assume many shapes and often occur in series or families. Measurements of their forward speeds are scarce, but estimates vary from a few kilometres an hour to as high as 64 to 80 kilometres per hour. Contrary to popular opinion, a waterspout does not "suck up" water to great heights, though it may lift the water level a few metres. The main visible cloud consists mostly of freshwater clouds produced by condensation of water vapour; however, a sheath of spray often rotates around the lower portion of the vortex tube.

One of the largest and most famous waterspouts, observed near Massachusetts on Aug. 19, 1896, was witnessed by thousands of vacationers and several scientists. Its height was estimated to be 1,095 metres and its width 256 metres at the crest, 43 metres at centre, and 73 metres at the base. The spray surrounding the vortex tube near the water surface was about 200 metres wide and 120 metres high. The spout lasted 35 minutes, disappearing and reappearing three times. Most waterspouts are smaller, with much shorter lives. This exceptional spout is an example of one that apparently was spawned by thunderstorm-squall conditions, similar to those that produce tornadoes over land.

There are few authentic cases of large ships ever being destroyed by a spout, although spouts are a dangerous hazard to small vessels. A few intense waterspouts have caused deaths when they moved inland over populated areas. The belief that firing a cannonball or other projectile into a spout can "break it up" has no scientific foundation.

Whirlwinds. In the general sense, a whirlwind is any rotating mass of air or atmospheric vortex. The term is, however, commonly restricted to atmospheric systems smaller than a tornado but larger than eddies of microscale turbulence. A whirlwind is usually named after the visible phenomenon associated with it; thus there are dust whirls, or dust devils; sand whirls, or sand pillars; and fire, smoke, and even snow whirls, or spouts.

Differences from tornadoes

In contrast to the pendant form of the tornado funnel, a dust or sand devil develops from the ground upward, usually under hot, clear-sky conditions. The whirl shape is normally that of a cylindrical column or an inverted cone. The axis of rotation is usually vertical, but it may be inclined. The direction of rotation may be either clockwise or counterclockwise. Vortices with a horizontal axis of rotation are sometimes called rolls, or rotors. Dust and sand whirls are not nearly as violent as tornadoes, although jackrabbits have been lifted by the more intense vortices. The whirls measure in diameter from several centimetres to a few hundred metres, and visible heights from a few metres to at least 1,500 metres. This is probably not the upper limit, for sailplane pilots have used their spirally ascending currents to soar to above 4,570 metres. Like tornadoes and waterspouts, dust and sand devils often appear in groups or series. Eleven of them were simultaneously sighted in Ethiopia, and in the Mojave Desert in eastern California a series of smaller whirls followed in the wake of a larger primary vortex. Such secondaries are sometimes referred to in India as "dancing devils."

Fire whirlwinds are a problem to the forest rangers who must cope with them. A historical example of a great fire vortex, produced by war, is that which formed over Hamburg following a massive aerial bombing during the night of July 27–28, 1943. The fire fueled a storm of counterclockwise rotation 1.6 to three kilometres in diameter and nearly five kilometres high, with winds estimated to be more than 160 kilometres per hour in some sections.

OCCURRENCE AND DISTRIBUTION

Tornadoes. Tornadoes strike in many areas of the world, but nowhere are they as frequent or as fierce as in the United States. More than 1,100, for example, were reported there during 1973 alone. Direct comparisons of relative tornado frequencies in various countries are biased because observational data are often lacking in sparsely settled regions. It appears, however, that Australia, where several hundred per year have been reported, has the dubious honour of second place. Other countries reporting tornadoes include, but are not limited to, Great Britain, Canada, China, France, Germany, The Netherlands, Hungary, India, Italy, Japan, and even Bermuda and the Fiji Islands.

Distribution and frequency of tornadoes

A vast "tornado belt" embracing the Great Plains of the United States and the southeastern portion of the country is threatened by tornadoes every year (Figure 42). Every state in the nation, including Alaska and Hawaii, has experienced twisters. The average frequency varies from more than 100 in Texas to fewer than three in the far western and most of the northeastern states.

A more important criterion for gauging tornado severity is the average number of tornadoes in a unit area, such as a square kilometre or a two-degree square on a map. Computations of this tornado density for a 45-year period show that the greatest concentration of tornadoes per unit area is found in the states of Oklahoma and Kansas. The area with the greatest potential for casualties is that which combines a high tornado incidence rate with a thick population concentration. Southwestern Oklahoma, for example, has the highest tornado incidence per unit

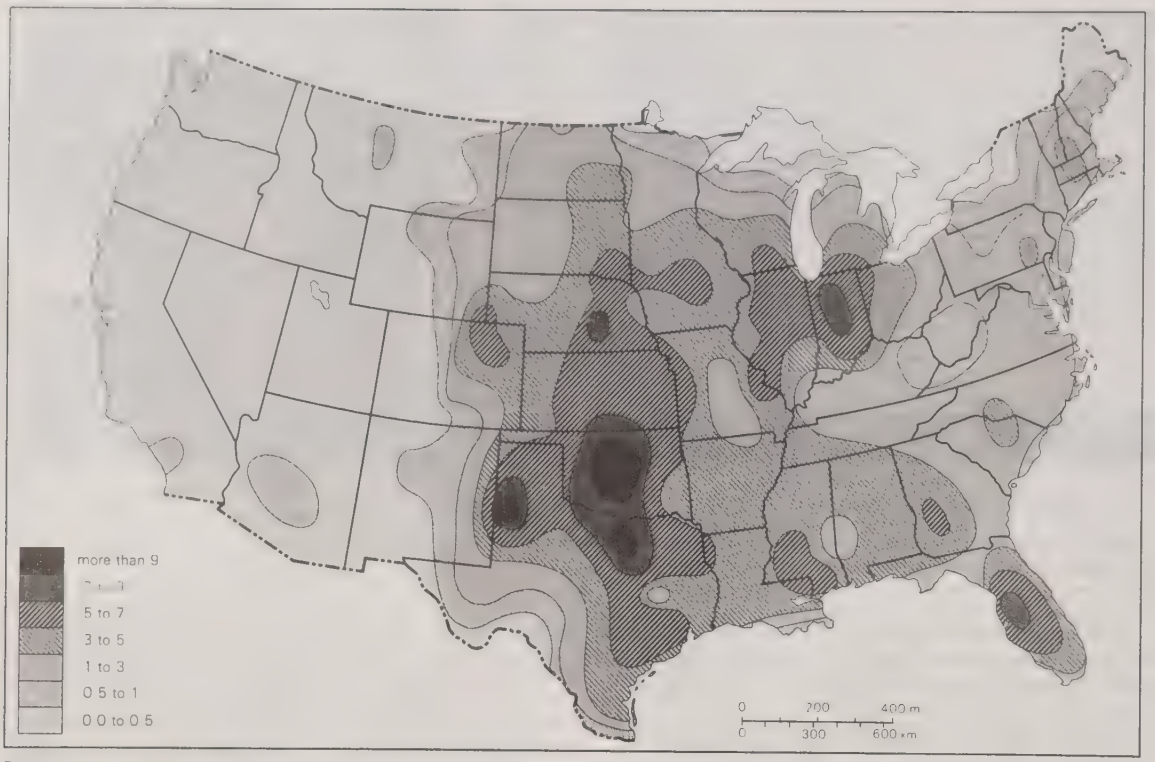

Figure 42: Annual frequency of tornadoes in the coterminous United States. (Based on 1953–80 data.)
NOAA

area, but because it is thinly populated as compared with the Chicago area, which has less than one-half its tornado incidence, casualty potential for Chicago is much greater. Although the probability that a specific locality will be struck by a tornado in any one year is very small, this low probability does not mean that such an event will not happen. An extreme example of an apparent defiance of probability statistics took place in Codell, western Kansas, a small town hit by tornadoes on the same date, May 20, in three successive years, 1916, 1917, and 1918.

Seasonal and diurnal variation

Tornadoes may occur during any month of the year. Normally, for the United States as a whole, the month with the most tornadoes is May; and more than half the year's total occurs during the three months of April, May, and June. The lowest frequency is in December and January. No season of the year is free from tornadoes, but in spring and summer they are five times as numerous as in winter and fall.

Tornadoes are generated from severe thunderstorms, which form readily between warm, moist air from the south or southwest and contrasting cool, dry air from the west or northwest. A squall line of severe local storms often develops along this boundary, and sometimes a family of tornadoes is spawned. In February, warm, moist air from the Gulf of Mexico begins to penetrate the Gulf states. As it continues its northern and eastern penetration, tornado frequencies reach their peaks during April over the southern Atlantic states, during May over the southern Plains states, and during June over the area extending from the northern plains to western New York state. In the summer and fall the decreasing contrast between the air masses results in a reduction of tornado incidence in most sections, although they may develop from the severe thunderstorms associated with unstable air masses, especially in Florida, where tornadoes are often associated with hurricanes. During December and January, cold air dominates the country, and the moisture-temperature relationships required for tornado genesis are not usually present.

Although tornadoes may strike at any hour of the day or night, they generally form during the middle or late afternoon, between 3:00 to 7:00 PM, the period most favourable for the development of severe thunderstorms from which they are bred.

Waterspouts. The worldwide distribution of waterspouts is difficult to determine because most of them occur over oceans and their detection depends on observations from coasts or from ships or airplanes. They are most frequent over tropical and subtropical waters; many of them have been observed over the Gulf of Mexico, off the coast of Florida and the Bahamas, and over the Gulf Stream. The spouts are common off the west coast of Africa near the Equator and off the coasts of China and Japan, but they may appear in unexpected places, such as the Grand Banks of Newfoundland and even near Seattle, Wash. As mentioned earlier, one of the largest observed waterspouts occurred off the coast of Massachusetts. A broad spout estimated to be 30 metres high and 210 metres thick appeared off the California coast in 1914, and one offshore from New South Wales, Australia, had a measured height of more than 1,500 metres.

The most common season for waterspouts in the Northern Hemisphere is between May and October, but they may appear at any time of the year or of the day or night.

Whirlwinds. Every summer hundreds of thousands of dust and sand devils travel across the arid and semiarid regions of the world. Only an extremely small fraction of such whirls are observed, however, because desert areas are sparsely settled. Observers report that whirlwinds are sighted almost daily during the hot season over the Sahara and the arid regions of Australia and the southwestern United States. They also are common over sections of India and the Middle East. An extensive scientific census of dust devils near Tucson, Ariz., was taken from June 23 to July 28, 1962. A total of 1,663 whirls were spotted, and the daily average was near 80.

Dust devils may, at times, develop in more temperate weather. They have even been observed as far north as the subarctic.

Diurnal frequency and duration

Dust and sand devils are usually most active over desert areas in the early afternoon, 12:30 to 2:00 PM, local standard time. These times precede by several hours those at which the maximum air temperature is recorded in a standard, shaded instrument shelter 1.5 metres above the ground. One reason for this apparent anachronism is that the much hotter sand surface attains its peak temperature earlier than the air at the 1.5-metre level.

The life of a dust or sand devil may be longer than visual observations indicate, because the vortex itself does not depend on the visible material forced into it. Durations vary from several seconds to about seven hours, but most dust devils probably last less than five minutes, and few persist for more than an hour. The larger, more vigorous whirls have a longer lifetime than the smaller vortices. One large dust devil, with a height of about 750 metres, lasted for seven hours as it traveled 64 kilometres on salt flats in western Utah. And in northwestern Mexico a large whirl formed at the end of an embankment and remained there for four hours.

PHYSICAL CHARACTERISTICS OF THE VORTICES

Although the visible characteristics of tornadoes, waterspouts, and other atmospheric vortices are well known, details regarding the distribution of velocity, pressure, energy, and particulate matter within them are lacking.

Tornadoes and waterspouts. Tornadoes destroy all standard measuring instruments; hence, most values given for velocity, pressure, and energy distribution have depended on theory and engineering damage estimates. Since the 1940s, however, radar, instrumented aircraft, and photogrammetric techniques have provided some quantitative data for analysis of the vortex structure.

Velocity distribution

The first quantitative observation of the distribution of tangential and vertical speeds within a tornado was made from scaled movies of the debris and cloud fragments in a tornado in Dallas, Texas, on April 2, 1957. The tornado was fairly stable and relatively small, with a spotty damage path. The variation of the tangential (rotational) velocity with radius at the 300-metre level is shown in Figure 43, in which the tangential velocity is seen to rise steeply from zero at the centre of the vortex to 240 kilometres per hour at about 60 metres from the centre and then fall off more gradually. This type of velocity distribution closely resembles the Rankine (theoretical) combined vortex (dashed and dotted lines in the Figure), in which the inner core is assumed to rotate with a constant angular speed, designated by the Greek omega (Ω) and corresponding to the rotation of a solid body. The tangential velocity is the product of the constant angular speed times the radius of the vortex. This is expressed in the equation $v_1 = \Omega r_1$, in which v_1 indicates tangential velocity and r_1 the radius distance. Hence, for this particular tornado, the tangential velocity in the inner core at the 300-metre level was almost directly proportional to the radius until the maximum speed (indicated by vm) was reached at the corresponding radius (rm). At this point, $vm = \Omega rm$.

Adapted from H. Kuo, *Journal of the Atmospheric Sciences*, vol. 23, no. 1 (January 1966)

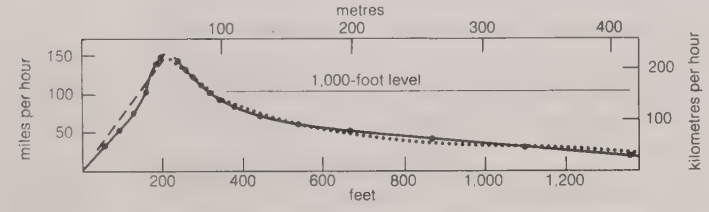

Figure 43: Variation of the tangential velocity with radius at the 300-metre level in the Dallas tornado on April 2, 1957. Dashed and dotted line represents the theoretical values; solid line represents observed values.

The tangential velocity distribution in the outer portion of this two-celled vortex follows closely the relation $v_2 r_2 = C = \text{constant}$. Hence, $v_2 = C/r_2$, or the velocity is inversely proportional to the radius. The velocity profiles for the 90- and 30-metre levels showed somewhat greater deviation from the Rankine (theoretical) vortex, possibly because of frictional effects near the ground. The peak tangential speed for this tornado was 274 kilometres per hour, at a radius of 40 metres and elevation of 69 metres.

Vertical speeds are measured by tracking debris in the air and correcting for free-fall velocities (which are not related to the tornado-derived speeds). Isotachs (lines of equal value of wind velocity) of these vertical speeds are depicted in Figure 44, in which distances are in metres and speeds in metres per second. A jet of strong vertical flow extends upward from a high-speed centre at 41 metres,

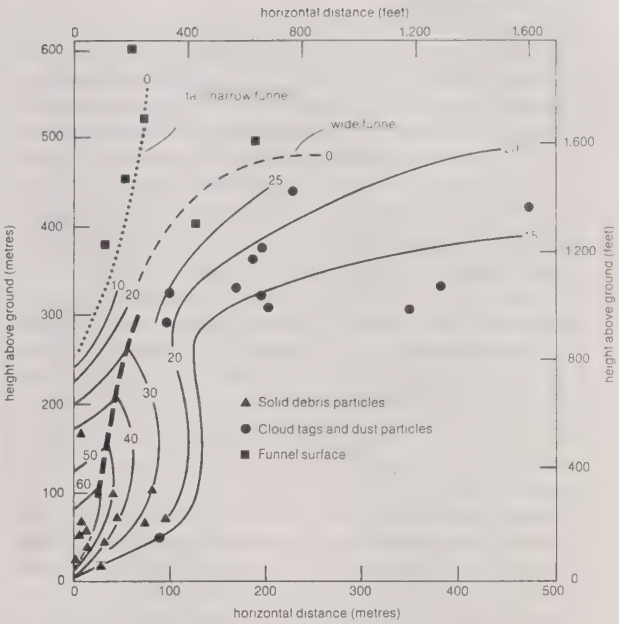

Figure 44: Distribution of the vertical wind velocities (in metres per second) in the Dallas tornado on April 2, 1957.
Adapted from H. Kuo, *Journal of the Atmospheric Sciences*, vol. 23, no. 1 (January 1966)

but the jet disappears near the 300-metre level. Above this altitude the line of zero velocity values at any one time appears to coincide with a zone of moisture condensation around the funnel. This indicates that the upper portion of the funnel probably does not act as a sink mechanism, in which air condenses at high levels and then sinks to lower levels. Whether the horizontal and vertical velocity distributions presented for the Dallas tornado are typical of most other tornadoes is uncertain.

Pressure, heat flux, and energy

No direct measurements have been made of pressures within a tornado, although barographs outside the zone of destructive winds have recorded the sudden drops of pressure associated with the tornado passage. By the use of theoretical relationships between wind and pressure and evaluation of damage patterns, however, some estimate of the distribution of pressure may be obtained.

Although standard barographs are not designed to register the rapid changes of pressure produced by a tornado, there have been cases in which barographs or aneroid barometers on the fringes of the zones of maximum winds have done so. Pressure drops of 100 millibars (or 10 kilopascals), about 10 percent of normal atmospheric pressure, are not uncommon, and a fall of 200 millibars has been reported. Because these changes may occur within an interval of less than 30 seconds, the normal pressure inside a building does not have time to adjust to the fast reduction of pressure outside, causing explosive or "suction" effects. Roofs are lifted and walls are blown outward.

Calculated values for the kinetic energy of a typical tornado vary from 10^{10} to 10^{13} joules (10^4 to 10^7 kilowatt-hours). The energy input required to generate this organized motion is probably 10 to 100 times as great. For comparison, the total energy (including radiation) of the 20-kiloton nuclear bomb dropped upon Hiroshima was about 10^{13} joules (10^7 kilowatt-hours). Any theory of tornado development must explain how the potential energy of the environment is converted into the organized kinetic energy of the tornado vortex.

The lower portion of a tornado funnel often appears as a mass of dust and debris picked up by the vortex. The rim of the funnel is usually rendered visible by clouds produced by the condensation of water vapour. The inner core is almost cloudless. Heavy rains and hail are often associated with the severe thunderstorms from which tornadoes develop. Waterspouts sometimes draw fish and frogs into the vortex and then drop them onto land.

Dust devils and "fair-weather" waterspouts. Until quite recently few detailed measurements of horizontal and vertical velocities in dust devils had been made. Quantitative data on "fair-weather" waterspouts are still sparser, but it

Velocity distribution

is probable that the velocity distributions are similar to those of dust devils in many respects.

Recent measurements in dust devils indicate that the variation of the tangential velocity with radius corresponds closely to that of the Rankine vortex, as described earlier. Tangential speeds of 40 kilometres per hour have been measured and are probably common in moderately strong vortices. Velocities of more than 80 kilometres per hour probably occur in some of the larger, more vigorous dust devils. Sailplane pilots have measured vertical speeds of 16 kilometres per hour in moderate whirls and 32–48 kilometres per hour in stronger vortices.

Research indicates that a mature dust devil may be divided into three vertical regions. Region 1 is a shallow frictional layer near the ground. It is there that the air and dust are entrained into the core of the whirl. Above that shallow boundary layer is Region 2, a stable vortex in which the pressure force and centrifugal force are in balance. Region 3 begins where the top of the vortex becomes unstabilized and the turbulent air diffuses radially with height.

Pressure drops of a few millibars are typical in dust devils. Details regarding the pressure distribution are not known, but there is good evidence that pressure in the well-defined vortex (Region 2) follows a radial distribution similar to that of the Rankine vortex.

The main energy source for a dust or sand devil is the heat flux from the hot surface, although, under certain circumstances, dust or sand devils can be formed in a moderate surface temperature environment, provided that other necessary meteorologic conditions are fulfilled. A heat transport (flux) of 0.7 calories per square centimetre per minute was measured over a desert dry lake in California. For a circular area with a 10-metre diameter, this flux would correspond to a net upward heat transport of about 50,000 watts. A dust devil moving over a heated surface utilizes this energy to maintain itself. When dissipative forces, such as surface friction and eddy interaction with the environment, exceed the available energy, the whirlwind is destroyed.

THEORIES OF VORTEX FORMATION: THE GENERATION OF TORNADOES, WATERSPOUTS, AND WHIRLWINDS

At present, meteorologists have not generally agreed on any particular quantitative theory for complete explanation of the formation and maintenance of tornadoes, waterspouts, and other vortices. Some of the more notable theories that seem to fit atmospheric observations and laboratory simulation experiments are reviewed in this section. Any theory of vortex formation must explain, quantitatively, how the potential energy of the environment is converted into the organized rotational motion of the vortex.

Downward development theory. One kind of tornado formation theory assumes that the tornado vortex develops downward from the parent thunderstorm cloud. It is known that the bases of cumulonimbus clouds associated with severe thunderstorms have stronger rotation than those of ordinary thunderstorms. Further, the visible funnel appears to work downward toward the ground. This visible aspect does not necessarily mean, however, that the tornado vortex itself must originate at upper levels, since spirally rising air currents could produce a cloud sheath resulting from condensation of water vapour in the rising air.

Vortex-contraction theory. During the latter half of the 20th century radar has been extensively employed in the detailed analysis of severe storms. The use of radar in this area is based on the fact that clouds and precipitation "backscatter" the emitted radiation, thus producing an "echo" that can be photographed on a radarscope. Areas of relatively clear air ("echo-free") are delineated by contrast. Radar meteorologists have contributed significantly to both theories of tornado development and the methods of warning.

The "hook" echo

A photograph of a historically significant echo associated with an Illinois tornado is reproduced in Figure 45. A projection from the mother thunderstorm lengthened and curved in a counterclockwise manner to form an echo resembling a "figure 6" or "hook." The hook itself is not the tornado, but tornadoes are often associated with echoes of this shape. An analysis of echo alignments and motions and of surface pressure and wind distribution revealed that this distribution corresponded to that of a "tornado cyclone" detected in 1948. This kind of cyclone is a small low-pressure area of about eight to 40 kilometres in cross section; the 1948 tornado funnel was 1.6 to 3.2 kilometres south of the cyclone centre, and it has been suggested that the contraction of this cyclone would result in an increase in angular momentum and a large upward motion, producing condensation within the tornado cyclone.

Figure 45: Hook echo of a tornado in Champaign, Ill., photographed on a radar scope on April 9, 1953. This was the first occasion on which the hook echo, an important clue in the tornado warning system, was recognized and photographed.

Severe local-storm theory. A model for severe local storms that may produce tornadoes is shown in Figure 46. It includes a strong shearing of wind (scissorlike action) veering (turning, in clockwise sense) with height. The essential features of the model are the following:

1. An updraft of warm, moist air, in which most of the streamlines (lines following flow paths) turn counterclockwise (cyclonically) through about 270 degrees.
2. A downdraft within the precipitation areas ahead of the updraft.
3. An extensive overhanging radar echo ahead of the storm.
4. A region of low reflectivity or "vault" in which there is a persistent strong updraft. The largest hail usually falls in the area of intense echo surrounding the vault.

Adapted from K.A. Browning, *Journal of the Atmospheric Sciences*, vol. 21, no. 6 (November, 1964)

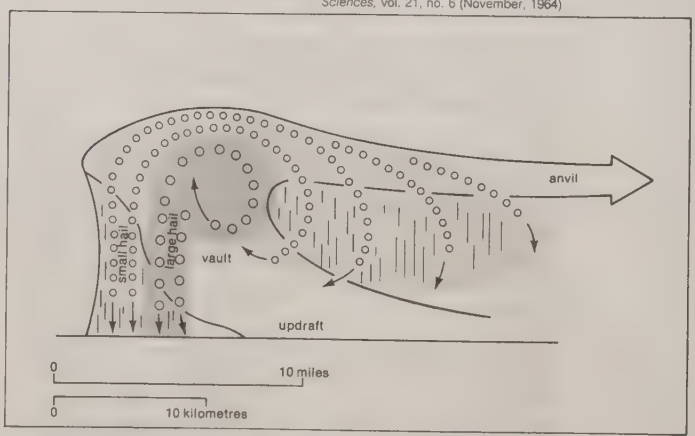

Figure 46: Vertical section illustrating precipitation trajectories in different parts of a severe storm traveling to the right of the prevailing winds in the middle troposphere.

5. A hook-shaped echo that has a definite counterclockwise circulation. When a tornado forms, it is usually near the forward edges of the hook. It is believed that the hook-shaped echo results from rotation within the strong updraft. Large hail, frequently associated with tornado-breeding storms, requires a vigorous updraft for its formation. The development of a core of rotation within the updraft appears to be required for the genesis of severe storms moving to the right of the environmental winds in the troposphere. It has been suggested that the necessary core of rotation within the updraft could develop only when the updraft was strong enough to generate the growth of giant hail.

The lightning hypothesis

Electricity theory. It is known that lightning, when it accompanies a tornado, has peculiar characteristics. The high-voltage discharges have been described as brighter and bluer than those from other storms. A farmer who had looked up into the core of a tornado later described the walls as constantly illuminated by lightning flashes that zigzagged from side to side. So it is not strange that lightning has been hypothesized as the source of energy for the genesis or maintenance of tornadoes. Electrical theories for tornado formation are not new, but have been revived in modern studies.

Electrical energy is assumed to be transferred to the vortex or the incipient vortex by mechanisms such as the electromagnetic acceleration of ions or heat released from lightning strokes. These electrical transfer mechanisms have been analyzed on the basis of theory and the use of simulated tornado vortex experiments. It has been concluded that the electrodynamic acceleration of ions is unimportant for either the genesis or maintenance of a tornado. Although the heat released from lightning could initiate updrafts, this lightning energy would have to persist for several minutes in order to generate a tornado. Laboratory experiments indicate that electrical discharges in the centre of an intense vortex inhibit, rather than strengthen, its circulation.

These negative results do not mean that electrical phenomena might not produce important indirect effects: the rate of release of latent heat from condensation and precipitation could be influenced by the electrodynamic acceleration of charged particles in the vortex.

General vortex theory. Because of the complex interrelationships of the meteorological factors that must operate together to develop a tornado, a quantitative dynamic theory for generation and maintenance of these twisters is very difficult to formulate.

A theory, nevertheless, has been formulated for the dynamics of atmospheric vortices, which applies not only to tornadoes but also to milder twisters, such as dust devils and other whirlwinds. This model is based on the pre-existence of two atmospheric conditions considered to be essential for the genesis and maintenance of the vortices: (1) a thick layer of unstable stratification, either with or without the influence of the latent heat of condensation; and (2) existence of vorticity. The first factor produces sinking because vertical instability aids strong updrafts and the rising air mass is replaced by horizontally converging air. The second factor provides a source of momentum for the development of a stronger tangential velocity as the air converges into a smaller radius. Thus tornadoes and waterspouts, because they are basically convective in nature, are similar to dust devils and fire whirlwinds. For all of these vortices the ratio between horizontal extent and vertical extent (ranging from $1/5$ to $1/50$) is small in comparison to that for hurricanes and extratropical cyclones (from about 10 to 200). Because only the general mechanisms that govern the vortices are of concern, differences depending on atmospheric structural details have been disregarded and it is assumed that all of these small-scale vortices are governed by the same simple model.

Atmospheric conditions essential to the development and maintenance of vortices

From a set of equations for atmospheric vortex motions, the effective radius of the innermost cell assumed to be developing into a vortex was found to be inversely proportional to the one-third power of the initial vorticity and directly proportional to the one-third power of the product of the eddy viscosity coefficient and the effective depth of the unstable layer. When this layer is shallow, only relatively small and weak whirlwinds, such as dust devils, can be produced.

Two-cell solution

For a steady state (equilibrium) circular vortex, two solutions have been derived. The first is a two-cell type, with descending motion in the centre and ascending motion in the outer part; the second is a one-cell type. The theoretical descending motion in the centre is compatible with the observed sparseness of particulate matter in the cores of tornadoes and dust whirls.

The two-cell solution also indicates that the pressure distribution in the outer portion of the vortex is the same as the flow in the outer part of the Rankine combined vortex described earlier.

Other solutions for a steady state vortex are possible, but it appears that all of them have the following common characteristics:

1. The maximum vertical speed is proportional to a stability factor and increases linearly with height in the unstable layer.
2. The maximum tangential speed is proportional to the angular momentum and the square root of the stability factor; it is inversely proportional to the square root of the coefficient of eddy viscosity, but it is almost independent of the height.
3. The radius of the maximum tangential wind is proportional to the square root of the eddy viscosity coefficient divided by the stability factor.
4. The tangential flow outside the radius of the maximum tangential wind closely approximates the relation in which the product of velocity and radius is a constant ($vr = C$).

The theoretical results of the dynamic-model theory agree quite well with observations of tornadoes and dust devils.

(N.R.W./Ed.)

Hurricanes and typhoons

Hurricanes and typhoons are severe tropical storms characterized by wind speeds exceeding 32 metres per second. The winds spiral inward toward the storm centre (characteristic of cyclonic flow), clockwise in the Southern Hemisphere and counterclockwise in the Northern Hemisphere. At the centre of the storm there are light breezes, even the proverbial calm. Barometric pressure decreases rapidly toward the centre, where record low pressures have been recorded. Wind speed, humidity, and rainfall increase toward the central zone, termed the eye, where they suddenly decrease. If there is a strong downdraft in the eye, temperatures there may be some 8° to 10° C higher than in the storm's main body.

Such tropical cyclones are not common. Their total number in a given year may vary from 30 to 100, with about one-quarter occurring near Southeast Asia, one-seventh in the Caribbean and adjacent waters, and one-tenth in the southwest Pacific and Australian waters. They play a noticeable, if spasmodic, role in the general circulation of the atmosphere, transporting large amounts of warm, moist air from very low to middle latitudes. It is estimated that a mature hurricane may export more than 3,500,000,000 tons of air per hour, thus contributing greatly to redistribution within the troposphere. The development of a hurricane entails the release of large amounts of energy and the transfer of substantial quantities of water over several degrees of latitude.

ORIGINS

A tropical cyclone is likely to occur whenever several of the following prerequisites occur simultaneously: (1) latitude sufficiently high (5°–6°) for the Coriolis force (see above) to be appreciable; (2) a warm-water surface (at least 27° C) of sufficient area to supply the overlying air with large amounts of vapour; in some cases a cyclone may form over water at 23° or 24° C if much colder air is present at higher altitude; (3) pronounced instability in the air column or relatively low pressure at the surface and often an anticyclone aloft; (4) little or no vertical wind shear (shearing effect produced by the movement of one air mass past another). These conditions are most likely to occur over the oceanic areas where the intertropical convergence zone moves 10° or more away from the Equator.

Wind flow and cyclonic triggering

The Coriolis force is proportional to both the latitude and the angular velocity (rotational speed) of the Earth. At these low latitudes, the value of the Coriolis force is minimal; this is why, in large and shallow tropical depressions with very weak winds, the pattern of air flow is indistinct. The general instability and enormous vapour load make the air most susceptible to any triggering factor and especially to convergence due to external wind flow. Convection may rapidly become tumultuous. With a strengthening of convection, the centripetal wind flow gains speed; soon the angular velocity component of the Coriolis force becomes sufficient to impart a definite cyclonic curvature to the air flow, and a cyclone becomes established. The input of warm, very moist air continues. Large-scale condensation of moisture occurs during the ascent, and enormous amounts of previously latent energy are released. This energy results in stronger winds, which in turn lead to the intake and uplift of larger amounts of humid air, with a further release of energy. The evolution from tranquil tropical depression to violent tropical cyclone takes four to eight days. Strong vertical wind shear (*e.g.*, by a jet stream overhead) would impede convection and prevent the development of the cyclone. Latent heat is the main source of energy in a tropical cyclone. Thus, a rapid inflow of dry air can reduce the cyclone to a much slower tropical depression.

Development and classification. The life span of a tropical cyclone may vary from a few hours to nearly three weeks; most cyclones last five to 10 days. All of them begin as tropical depressions over warm oceanic waters over an area 200 to 400 kilometres across. They may remain in this formative, rather shapeless stage, with bulging but not closed isobars (lines of equal pressure) and pressure above 1,000 millibars for many days. A substantial number of tropical depressions never evolve to a cyclonic stage.

The immature stage of a tropical storm begins when the wind gains strength (from the 65 to 87 kilometres per hour associated with weak storms to the gale-force winds of 89 to 118 kilometres per hour characteristic of cyclonic storms) and follows a spiraling path toward a distinct centre. The eye measures five to 15 kilometres across. Wind and pressure gradients are very steep around it. Some isobars are closed, and pressure falls below 1,000 millibars. The diameter decreases to 80 to 200 kilometres. Many storms remain at this stage throughout their life. In some there may be occasional gusts of hurricane force.

Many investigators hold that the term tropical cyclone (hurricane, typhoon) should be reserved for the mature stage of intense tropical storms, those in which wind speed exceeds 118 kilometres per hour usually over an area of at least 100 kilometres in diameter. Isobars are very nearly circular at first, and pressure falls well below 1,000 millibars at the centre, but gradients become less steep. The size of the cyclone as shown by the closed isobars may vary considerably from just over 100 to more than 2,000 kilometres in diameter at the surface, with a 20- to 100-kilometre eye.

The cyclone may reach a decaying stage in which the pressure rises and the wind slows down while the eye becomes wider and less distinct and a revitalized stage in which the inflow of cold, moist air brings new energy and a frontal structure arises.

Classification of storms

The international classification, in use since the 1950s, is based on wind speed. Tropical cyclones are evaluated according to several objective criteria: (1) minimum pressure; (2) wind speed that may be measured over five, three, or one minutes or in single gusts; (3) wind direction; (4) rainfall quantity and intensity; (5) area or diameter of the widest closed isobar or the isobar of 1,000 millibars, or area or diameter with winds more than 87 or 118 kilometres per hour; and (6) point of origin and characteristics of the track.

Core structure. A record low pressure of 870 millibars was measured in the eye of a typhoon in the Guam area in October 1979. The lowest pressure on land, 892 millibars, occurred in a 1935 Florida hurricane. The pressure gradient may reach three millimetres per kilometre; pressure has been observed to fall 38 millibars in 30 minutes and 16 millibars in five minutes.

Radar observations show the dynamic core of the cyclone as a near-circular, echoless area, also revealed by the inward spiraling rainbands, 10–20 kilometres wide and 100–150 kilometres long, which converge to form a central ring. The core (eye) is quite distinct from the barometric centre, which may be up to 80 kilometres away from it on the poleward side while the cyclone travels westward and later on to the equatorward side when the cyclone heads eastward. The position of the core near the ground also differs from its position as shown by radar, because the rain that causes the radar echoes occurs at about the 700-millibar level.

Travel and modification. A tropical cyclone traveling over a land surface loses much energy because of increased friction, and wind speeds are reduced. Most of the cyclones that reach the high Vietnamese and Malagasy escarpments die out immediately. On the other hand, the low Western Australian plateau is no obstacle, and cyclones have been known to travel 1,500 to 1,800 kilometres over it. Hurricane "Camille" (1969) traveled 1,800 kilometres along a broad arc from Louisiana to Virginia, losing much strength but preserving its structure. The intake of much dry air, as occurs in high-pressure situations on the west coasts of Asia, North America, and Australia, fails to supply any further latent energy and may lead to the rapid decay and dissipation of the cyclone, especially if it travels over cool water. Similar developments occur on the east coasts of these continents but are less frequent because coastal waters are usually warmer and lasting high-pressure situations are less common in the hurricane season.

Mid-latitude occurrences

A most significant development occurs when a tropical cyclone happens to enter a long north–south pressure trough. The cyclone may then reach the middle latitudes without too much change or loss of energy. The intake of moist air is still possible, especially on east coasts, where warm currents (Gulf Stream, Kuroshio) are present.

When a stream of mid-latitude air is drawn into the cyclone, frontogenesis (formation of frontal structure) occurs, generally with the appearance of an extraordinarily active warm front due to the high speed of the original cyclonic circulation. This results in the new extratropical frontal structure of the revitalized cyclone becoming apparent on surface maps, while at altitude (500-millibar level and higher) the nonfrontal tropical features remain almost unchanged. At this stage three possibilities arise, namely: (1) the cyclone meets a large anticyclone and is rapidly filled, eliminating its centre; (2) the cyclone continues on its course for some distance and disappears gradually by infilling without much further change; or (3) the cyclone continues on its course until it enters a westerly stream where wind speed exceeds the wave velocity, in which case the transformation to full-scale mid-latitude depression rapidly extends upward and becomes total. For some time, however, the cyclone may remain distinctly warm and humid and relatively homogeneous, and the inner end of the frontal surface remains eccentric. In the meantime a cold front is likely to arise on the equatorward side, usually also eccentrically. Considerable amounts of moisture will condense and fall as rain. The additional energy thus released, combined with the more pronounced Coriolis force due to the higher latitude, causes the cyclone to travel at greatly increased speed. During this phase much damage may occur in coastal areas of Japan and the Atlantic United States.

PHYSICAL CHARACTERISTICS

The shape of the streamlines in a tropical cyclone is not a simple spiral, as it would be if there were no zonal (latitude belt) easterly winds around it. Because of the greater speed around the core, the zonal easterlies are slightly deflected outward before they begin their inward spiraling course toward the centre of cyclonic indraft. Also, downwind of the cyclonic spiral there is a hyperbolic (saddle-shaped) divide between the airstreams that flow into the cyclone and those that rejoin the zonal, easterly flow after having been deflected around the edge of the cyclone. Winds are weakest near this hyperbolic divide: there is no wind at all at the point where the air may be equally likely to flow into the cyclonic indraft or to flow away from it. This

is the stagnation point, and it is a necessary element of the cyclonic structure. The corridors of convergence that cross the stagnation point may be marked by a line of clouds, which are only small cumulus on either side of the stagnation point and build up to towering cumulonimbus both eastward and westward where the air streams crowd together.

A tropical cyclone is often preceded, at a distance of about 1,000 kilometres, by a short spell of fine weather due to divergence and subsidence in the prevailing (and preceding) easterly air flow. Pressure then begins to fall, but cloudiness does not appear until the cyclone is fewer than 300 to 500 kilometres away.

Wind velocity. Wind gusts fluctuate rapidly from 37 or 56 kilometres per hour to more than 185 kilometres per hour, even within two or three minutes, but there is no rhythm or regularity. Strong winds often are associated with rain bands. The highest gust velocities, recorded around the eye, may be close to 260 kilometres per hour. The strongest gust recorded (1966) reached 316 kilometres per hour. Within the eye, calms or light breezes prevail. Beyond the eye, the strongest gusts resume from the opposite direction.

The actual wind velocity is the result of two distinct movements—namely, the inward spiraling of the air streams and the progress of the cyclone as a whole along its path. The zonal wind strengthens or weakens the wind field, thereby extending or reducing the area of strong winds and making it asymmetrical. Before its recurvature, a cyclone lies in the trade-wind belt (zonal easterlies); its poleward side may already have hurricane winds 100 to 130 kilometres from the centre because the trade winds add momentum to that side of the spiraling flow. Conversely, the storm area is greatly reduced on the equatorward side. The speed and direction of travel of the cyclone and the strength and direction of the trade winds are, however, always minor elements in cyclonic wind patterns, the spiraling winds being paramount.

Onset of a tropical storm

Clouds and precipitation. The usual herald of a tropical storm is a broad trail of cirrus. Heavy showers of rain may fall on a coastline 500 to 600 kilometres ahead of the oncoming storm. Cirri depart in all directions at high altitude. A thin watery veil may pervade the air. Within a day or two, the storm appears as a distant wall of cumulonimbus. The middle and high clouds travel along divergent paths. The lower the clouds, the less direct the exit. Altocumulus may diverge by 20° from the tangents to the isobars. Low clouds, which may travel 50 metres above the ground, tend to follow a converging course. The wind freshens and rain begins to fall. Cloudiness suddenly becomes overwhelming. The wind becomes more violent and rain showers heavier. The heaviest rainfall occurs patchily just before the eye, in a radius of 20–50 kilometres, until one side of the wall passes over. There follows a 10–45-minute rainless interval with calm or light breezes while the eye passes overhead. Then follow the heaviest downpours and strongest gusts from the opposite direction, which occur beneath the steepest towering portion of the cloud wall. In coastal locations much sea spray is added to the rain. This second rainy spell is also likely to last longer, extending radially over a further 20–30 kilometres. The rain gradually decreases but may still last two or three days if there is enough moist air. The increase or decrease of rainfall intensity is normally decided by streamline convergence (confluence of air flow) or divergence, hence the spiraling bands of intense rain. Rain gauges may miss up to 50 percent of the rain because of the driving wind, and they may overflow before readings are taken. In some cases all instruments have been blown away. It is certain, however, that cyclones have brought the majority of the heaviest rainfalls recorded (*e.g.*, 1,583 millimetres in 24 hours in April 1958 to Aurère, on a mountain slope on Réunion Island, and 116.8 centimetres on a hillside at Baguio, Phil., in 1911).

When the hurricane's structure becomes revitalized, a renewal of precipitation occurs. The new rainfall zone is more distinctly asymmetrical with respect to the hurricane's track. The rain may reach 150 or even 200 millimetres in 24 hours at the most active point of the front, but in general it is 50–60 millimetres over some 20,000–30,000 square kilometres, enough to cause local flooding in some situations.

Energy of storms. The power of a typhoon K in ergs per second may be derived from the empirical formula relating power to the lowest pressure of the storm and the radius of the largest circular isobar, namely:

$$K = 0.71 \times 10^{22}(1{,}010 - P_{min})\,(R/111)^2,$$

in which P_{min} is the lowest pressure in the typhoon and R is the radius of the largest near-circular isobar in kilometres. The energy that is associated with very severe storms is about 10^{25} ergs per second by this formulation.

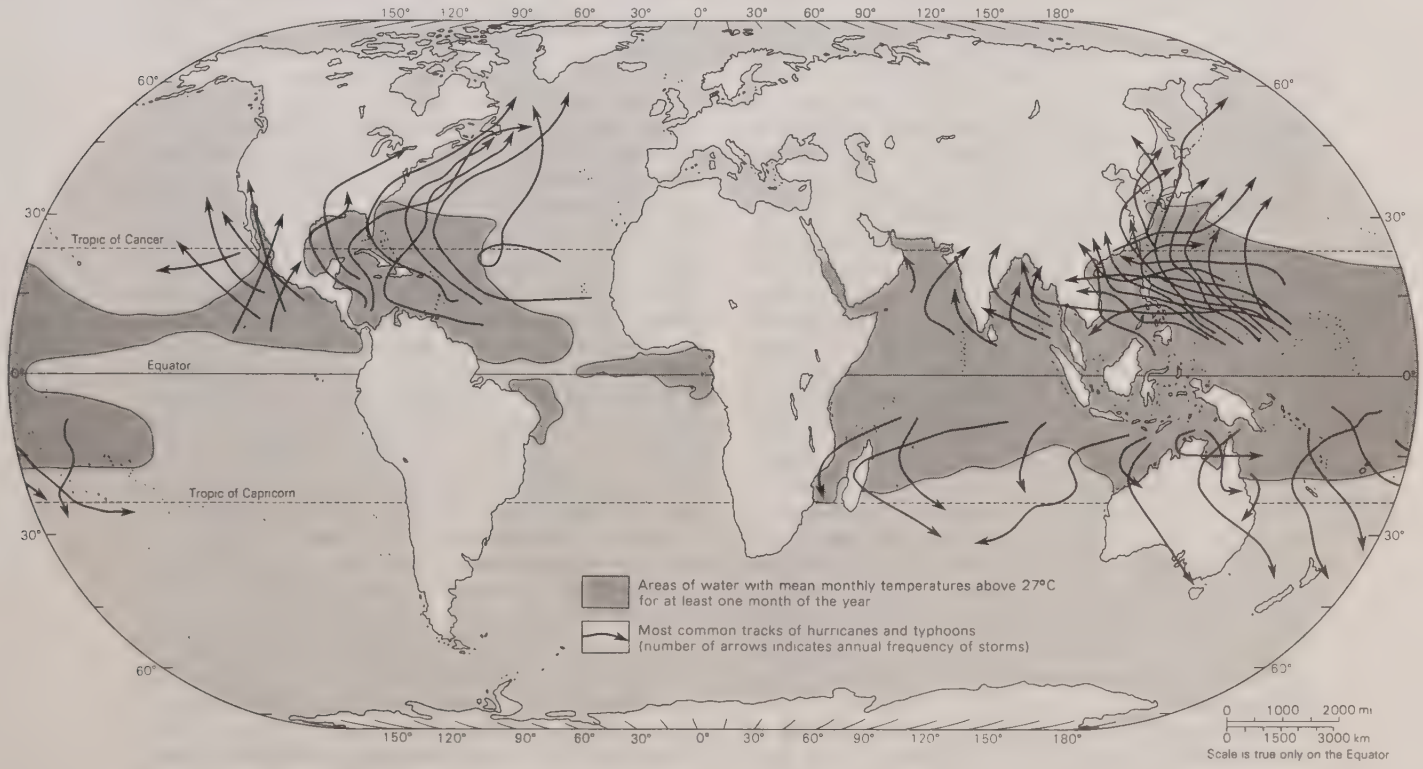

Figure 47: Major tracks and frequency of hurricanes and typhoons.

DISTRIBUTION

The average distribution and frequency of hurricanes and typhoons around the world are shown in Figure 47. More details appear in Table 5, which gives the frequency by area or region. Because of the cool surface waters, tropical cyclones do not originate in the eastern South Pacific and South Atlantic oceans (Figure 47).

Table 5: Average Frequency of Cyclones by Area

area	average frequency per year	total
East and south Asia		29
Northwest Pacific	21	
Bay of Bengal	6	
Arabian Sea	2	
North and Central America		14
Caribbean and northwest Atlantic	8	
East Pacific and west Mexico	6	
Australia and Oceania		9
Southwest Pacific and northeast Australia	6	
Timor Sea and west Australia	3	
Southwest Africa and islands		7
Southwest Indian Ocean and Madagascar	7	
World		59

Seasonality and frequency. Before 1940 many cyclones went undetected. At present every disturbance is detected by satellite photography. There are four main areas of origin of North Atlantic hurricanes: south of the Cape Verde Islands, the open waters east of the Lesser Antilles, the western Caribbean Sea, and the Gulf of Mexico. The early summer hurricanes usually begin in the Gulf of Mexico and western Caribbean, where water temperatures rise early because of the shallows and the nearby heated land. Low pressure farther north often allows the hurricane to enter the Gulf area. As the broad expanses of Atlantic surface waters warm to 28° C or more in late July and August, more hurricanes form much farther east, as far as the Cape Verde Islands. They gather more energy as they travel west before recurving over the West Indies. By mid-September surface waters are cooler, but outbursts of cold air aloft are likely; the area of origin moves west again to the Caribbean and to the Gulf of Mexico. The high-pressure outflow of continental air often pushes the recurving hurricane along a more easterly path so that it may sweep over Florida or the Atlantic seaboard.

Migration of tropical storms

Cyclonic tracks. Whereas a tropical depression may remain almost stationary, a tropical cyclone becomes smaller and more intense and begins to travel along a westward path, slowly at first, then at about seven to 28 kilometres per hour. The path gradually recurves toward the tropic, and the speed of travel decreases, in some cases practically to a standstill. The westernmost point is reached at latitude 15°–30° when the path gradually recurves toward the east and the speed of travel increases to 28–46 kilometres per hour and more. Hurricane "Carol" of 1954 hit New England after having traveled 650 kilometres in little more than 12 hours. Although tracks have often been described as parabolic, this is sometimes true only of their tropical part before recurvature. After recurvature the track may be almost straight or broadly waving. Some tracks continue westward and never recurve. Loops in either sense are uncommon but may occur any time because of outside pressure influences. To the east of Australia where there is a regular procession of anticyclones, during a period of 14 years there were nine single cyclonic and four single anticyclonic loops, four double loops and one triple loop among 93 cyclone tracks, and one case (January 1956) of two cyclones merging.

Some of the mid-latitude depressions that reach the British Isles from across the Atlantic have their origin as hurricanes east of the Caribbean. The last and still fearsome winds of a former Caribbean hurricane were experienced by the Norwegian explorer Fridtjof Nansen on Sept. 5–6, 1888, on the Greenland ice cap. The Galveston, Texas, hurricane of 1900 was still a recognizable storm after it recurved across the Atlantic, over Europe, and into Siberia.

Hurricanes maintain their enormous strength along the coast of North America, probably because of the latent energy supplied by the warm current waters. Even within the same region their paths may vary: New York City suffered badly in September 1821 while Boston was immune, but Boston was damaged in 1869 while New York City was untouched.

Tropical cyclones passing within 700–800 kilometres of the Pacific coast of Mexico send violent southerly winds against the shore, where they are known as cordonazos. On the average there are six such cyclones a year, mainly in the summer and early autumn, with a peak of two in September. The average duration recorded is one to eight days per storm. Most of these cyclones travel parallel to the coast for some distance and then recurve onshore before reaching the tropic. A few (fewer than one a year) continue northward without recurving and may then affect Baja California or, very rarely, southern California north of San Diego. Their traveling speed varies from nearly 13 kilometres per hour in June to more than 20 kilometres per hour in August and falls rapidly by September. A high-pressure situation over the western United States tends to hold a tropical cyclone farther offshore, and the resulting greater pressure gradient causes strong, hot winds. A pressure trough over the western United States induces a more rapid recurvature.

Cordonazos

An index of relative cyclonicity has been devised, based on the formula relating cyclonicity to the number of closed isobars and number of cyclones, namely:

$$j = \frac{1}{n} \Sigma a_i^2,$$

in which a_i is the number of closed isobars in the cyclone and n the number of cyclones in a given latitudinal zone.

DAMAGE CAUSED BY TROPICAL CYCLONES

Tropical cyclones can cause immense damage, both directly (by wind, pressure, and rain) and indirectly (mainly through storm surges and floods).

Wind and pressure damage. The wind causes damage that generally increases in proportion to the square of its velocity, according to the basic formula $P = KV^2$, in which P is the pressure exerted by the wind against vertical surfaces, V is the wind velocity, and K is a factor depending on air density and drag. A wind of 74–93 kilometres per hour strips leaves and small branches off trees; at 111–130 kilometres per hour it can topple shallow rooted trees or snap weaker trees outright, blow down thin walls, shift roofing materials, and occasionally lift a whole roof. A wind of this force may blow in large glass windows. At about 130 kilometres, lifting of roofs and snapping of trees is general. Hurricane winds may exert a pressure of more than 400 kilograms per square metre (82 pounds per square foot) on tall structures and can flatten weak buildings at first impact. Gusty winds, combined with a suitable period of vibration of a given structure, have a dynamic effect because they may produce resonance (vibrations in phase), leading to breaking point. Damage also is caused to roofs and windows by the suction produced by strong winds on the downwind side, amounting to 0.5–1 times the windward pressure. As with tornadoes, whirlwinds, and waterspouts (see above), much direct damage is caused by the rapid fall of external pressures. The pressure differential could amount to 300–400 kilograms per square metre for a sealed structure. Damage may be increased by the fact that the strongest gusts, in excess of 185 kilometres per hour, occur immediately after the transit of the eye and blow in the contrary direction to the preceding gusts, thus adding considerable stress to any structures exposed to them. Loose objects lifted by the wind become missiles that shatter glass, batter walls, and flatten roofs. Wind causes injuries and deaths by toppling structures and hurling loose or torn objects about with enormous force. Since the eye may take from a few minutes to an hour or more to pass over a given point, depending on (1) the central or eccentric position of that point, (2) the size of the eye itself, and (3) the traveling speed of the cyclone, many victims are struck after they have left their shelters in the belief that the storm was over. The kinetic energy of the whole cyclonic system is nearly proportional to its power, but the amount of damage and loss of life depends on many other factors, among which lack of warning and insufficient prepared-

ness can be extremely significant. Furthermore, the torrential rain brought by a typhoon may erode the soil, causing landslides in mountain country and making streams and reservoirs overflow.

Storm surges

Indirect damages are mostly due to a storm surge. This is a complex surface deformation of the sea induced by the cyclonic winds on coastal waters, which surge as a sudden tide against the coast, flooding the countryside and impeding the flow of rivers. The level of the sea is raised by up to three metres for a period that may last several hours, depending on the characteristics and relative position of the cyclone and of the coastline affected. The level of the sea is raised an additional 0.5–1 metre by the low atmospheric pressure. Extreme tides recorded on the Gulf Coast were all due to hurricanes. Hurricane "Hazel" (1954) brought a 3.5-metre tide to North Carolina. The worst storm surge in Tokyo Bay (October 1917) rose 2.3 metres above normal. Ōsaka Bay had nine storm surges in half a century, one of them (Sept. 21, 1934) reaching 3.1 metres above normal. Most coastal cities are less than three metres above sea level and may thus be extensively flooded. Industrial plants in coastal areas may be badly damaged by salt spray and seawater. Pounding waves are an additional cause of damage to coastal installations and structures. Coastal erosion may reach catastrophic proportions. Most significant may be the cumulative effect of a close succession of two or three cyclones, as happened in North America in 1954 and 1955. Lakes are affected in the same way as the sea but over shorter periods. Because of their smaller dimensions, they may develop storm-surge seiches (oscillations) of remarkable amplitude; *e.g.,* the disastrous 5.5-metre swelling of the southern end of Lake Okeechobee in Florida in 1926.

WARNING AND TRACKING OF TROPICAL CYCLONES

Because of the small diurnal pressure changes common in the low latitudes, it is difficult to single out changes due to approaching cyclones. A local drop in pressure of more than three to four millibars in 24 hours (or over a distance of 500 kilometres or less) may be considered a danger sign. The development of markedly curved isobars moving toward the observer is a much more definite indication of an approaching cyclone, and the roughly circular shape of the isobars soon reveals the position of the cyclone's centre. A rapid increase in the height of any thermal inversion, as revealed by misty or hazy layers aloft, is often a sign of an approaching cyclone, as is reversal of the wind direction in altitude. Humidity is normally high and is no useful indicator, but cloud types and movements—*e.g.,* a sheet of cirrus or bright red sunsets—may provide a belated warning.

Indications of approaching cyclones

Clearer advance warning may be given by a long ocean swell with a slower frequency (two to four times the usual interval) than that of normal waves. This swell travels outward from the centre for hundreds of kilometres.

In Australia a cyclone warning station was set up on Willis Island, off the Queensland coast, in 1921. Special hurricane forecast centres have been maintained by the United States Weather Bureau since 1935.

If a ship reports strong winds or rapidly falling pressure, unusual squall activity, or even a wind flow unusual for the season, special observations at three-hour intervals are requested from all ships in the area, and warnings are issued. Because the shape of the cyclone's path mainly depends on the pressure pattern of the time (the cyclone tends to travel toward any locus of lower pressure and around or away from any locus of high pressure), a synoptic barometric map may allow a gross forecast of a cyclone's track. Pioneer flights into a hurricane took place in 1943. Regular aerial hurricane patrols began in 1945, reporting location, characteristics, and movements of any likely disturbance. Flights may be made into, through, and above the storm. The easiest access to the eye of a cyclone is from the side of the stagnation point, where the hyperbolic divide is located. Because this is essentially an area of very light winds, exact location is very difficult without the use of drift smoke signals. The smoke plumes soon reveal the direction of the air flow. The plume extending toward the lower pressure will follow the indraft-accosting spiral, which leads in the shortest time (but not as the shortest route) to the centre of indraft. A distinct, clear break along a line of growing cumulus to cumulonimbus clouds is likely to be due to the prevailing stillness at the stagnation point and may be taken as an indicator.

Tracking activities

Radar units provide warning of any storm within range. The characteristic spiral banding of dense clouds and rain makes cyclonic storms easy to identify. Satellites transmit photographs of any part of the Earth and its cloud systems. They give the most reliable and comprehensive coverage of cloud patterns and reveal storm systems from remote areas, where other methods of detection may not always penetrate. (J.G./Ed.)

CLIMATIC VARIATIONS AND CHANGE

The meteorologist's concept of climate is a dynamic one, including day-to-day changes of weather, the seasonal cycle, and small-scale variations of atmospheric conditions measurable over periods of two to 25 years. Long series of observations show something like a "beat" phenomenon, with an unevenly varying wavelength. This built-in variability of the atmosphere results from the varying time lag between any single cause and effect, from the interaction of multiple factors, and from mechanisms set in progress by one or more variables operating over different time scales. Climate is never stable but is subject to continuing oscillations, such as the waxing and waning of many atmospheric components over a variable period of 23 to 29 months. For these reasons it is necessary to define climatic variations of different wavelength and amplitude and to decide which qualify as short- or long-term fluctuations and which are part of the built-in, year-to-year variability and thus deserving of the rank of oscillations. (K.W.B.)

Seasonal cycle

Each year the Earth experiences changes in its radiation budget, and in the distribution of heat input into the atmosphere, in the course of the seasonal migration of the zenith Sun between 23° N and 23° S. These are far greater than any changes associated with the differences of one year from another and also are greater than the differences between different climatic epochs, except those resulting from the presence of extensive ice sheets during the ice ages. The seasonal changes are accompanied by a general northward and southward movement of the subtropical anticyclone belts and other main features of the atmospheric circulation, including expansion of the circumpolar vortex of upper winds over the hemisphere where it is winter and contraction of the vortex over the summer hemisphere. The seasonal migration of these circulation features, however, is on the average no more than 10° of latitude (and generally less than this in the Southern Hemisphere); *i.e.,* much less than that of the zenith Sun.

As a result of the seasonal migration north and south of the respective belts of cyclonic activity over the middle and high latitudes of each hemisphere and of the equatorial rain zone, many places quite regularly experience a wet season and a dry season each year. Near the Equator there are two wet seasons, as the rain belt associated with the zone of convergence between the surface winds from the two hemispheres moves north and south between its extreme positions. Over the continents the seasonal migration of this intertropical convergence zone proceeds farther into the summer hemisphere than it does over the oceans, presumably because the heating of the continents in summer weakens the subtropical anticyclone development, and the trade winds are correspondingly weak at that season over the continental sectors. The extreme case is Asia, where, in summer, the southwest monsoon winds, supplied from the Southern Hemisphere (where it is win-

Wet and dry seasons

ter), drive what is essentially the equatorial rain belt to latitude 30° N and the foot of the Himalayas. In the northern winter the Indian subcontinent is largely dominated by the northeasterly trade winds, and dry weather on the whole prevails except where these winds blow against the coast and mountains.

The highest and lowest temperatures of the year generally occur away from the main belts of disturbed weather and in conditions that allow periods of clear sky.

The seasonal migration of the wind zones and belts of cloud, rainfall, and cyclonic activity is not a smooth or continuous progression but occurs in stages. It is the end product of an alternating sequence of pulselike advances and retreats. Occasionally the successive pulses occur at nearly uniform time intervals, which presumably correspond to the common duration of some cyclic process in the atmosphere or involving atmosphere and ocean. The physical nature and origins of these cycles are not yet adequately accounted for in spite of much research. Some may represent no more than the normal life history of an individual anticyclone cell from its first appearance to its decay or rejuvenation. Others seem to correspond to a repeating cycle affecting much of one hemisphere, with intense development of the mid-latitudes westerlies, at one phase, followed by breakdown and the appearance of blocking or extended meridional (north–south) circulation cells. It is unusual for any of these sequences, however, to recur more than a few times before their regularity is lost. Their occurrence is prominent enough, however, to produce many statistical traces of preferred periods of around five, seven, and (especially) 30 days.

The 30-day oscillation

The 30-day oscillation is often expressed in a recurrent tendency toward periods of low barometric pressure, cyclonic influence, and stormy weather spreading in over Europe from the Atlantic about the end of each month, particularly from October to March, and toward anticyclonic influence culminating about the 15th to the 20th of each month. Calendars that are based on weather phenomena related to such cyclic oscillations have been produced through the years. The tendency for precision (or regularity) of the dates of these phenomena seems greatest in high latitudes in the sectors of the Earth affected and may indicate an origin associated with the onset of the polar winter darkness.

One other period length, the very curious one of about 26 months, is strongly marked in a monsoonal alternation between prevailing west and east winds in the equatorial stratosphere, and traces of it are found in the statistics of so many surface weather conditions in both low and high latitudes that it must be accepted as affecting also the lower atmosphere over the whole Earth. This also appears to be the time scale of the so-called Southern Oscillation. Like the other circulation cycles here mentioned, it is not altogether regular in its performance. The cycle length varies at least from 22 to 35 months, and as every third or fourth cycle is more prominent than the others, it also gives rise to an appearance of some roughly seven-year repetitions. At other times, it may cease to be discernible at all. Its occurrences presumably bear witness to an incomplete return of the oceanic and atmospheric heat economy to its initial condition in certain individual years. (H.H.L.)

Climatic change

Researchers are able to approach the study of climatic change with some confidence because of two main technological changes: a revolution in observational technique that has made possible continuous scrutiny of the entire depth of the atmosphere and the surface features of the land and ocean; and the computational and data-storage capabilities associated with modern electronics. Only in recent decades, however, has the observation of climate approached the level where such sophistication is possible. During the previous 100 years or so, instrumental records were usually limited to temperature (air and sea surface), pressure, and precipitation (largely over land). Prior to that, instrumental records were fragmentary at best and are available only from about 1700. For the millennium or two before the beginning of the modern era, literary, historical, and archaeological sources provide some data; but discussion of climate and climatic change in the more remote past depends on "proxy" evidence. Most such evidence arises from the ability to interpret the world's sedimentary rocks—those deposited by still or running waters, by the winds, or by moving or stationary ice, both grounded and afloat. Annually accumulated tree growth (tree rings) has been a further source. Carefully extracted cores from trees, bogs, lakes, glaciers, and the ocean floors have provided an intelligible record for the climates of the past 750,000 years, as well as a growing body of evidence for climates that date back much further.

Proxy evidence of climatic change

The usefulness of these proxy sources would be limited, however, without the development of accurate dating and calibration methods. Radiocarbon dating of organic remains, for example, offers reasonable precision back 40,000 years or so. The decay of other radioactive (unstable) isotopes yields dates back to the early history of the planet. Stable isotope chemistry, chiefly using deuterium (heavy hydrogen, or hydrogen-2), oxygen-16 and oxygen-18, and carbon-12 and carbon-13, does not provide dating information, but it does provide evidence of temperature changes, ice volume, and, by inference, ocean circulation. One recent dating technique is based on the study of reversals of the polarity of the Earth's magnetic field. Advances in isotope chemistry have also provided vital tools.

The picture that emerges from the evidence yielded by these relatively new proxy and dating techniques is of a fairly stable global climate. Nevertheless, there have been prolonged periods, of which the present is one, in which large changes have occurred. Dynamically, both ocean and atmosphere have many of the characteristics of chaotic systems. They obey firmly established dynamic and thermodynamic laws but do so in a nonlinear fashion that permits seemingly unlimited variability. Thus, there are meaningful patterns to be described in this account of climate and climatic change, but the chaotic element tends to obscure these regularities on any short-term view. In spite of, for example, virtually constant input from the Sun, only slowly changing atmospheric composition, and an even more slowly changing Earth surface, the daily weather pattern never quite repeats itself. Each season in each locality places bounds within which this variety can unfold; but within these constraints the climate is free to choose a very diverse set of realizations.

The aim of the study of climatic change is thus to detect the signal of substantive change behind a deafening clamour of short-term noise.

PRE-PLEISTOCENE CLIMATIC CHANGE

The present is an abnormal time for the climates of the world. Ice sheets cover Greenland and Antarctica, and permanent pack ice blocks the Arctic Ocean. The deep waters of the oceans are frigidly cold in all latitudes (mostly below 3° C). The vegetation map is strongly zonal, with treeless tundra on high-latitude land surfaces and luxuriant rain forest near the equator. It is now known that few of these characteristics were typical of most of the Earth's history, and some generalizations can be made about ancient climatic conditions, but detailed information is still fragmentary.

To reconstruct the Earth's climate in times prior to the Pleistocene epoch (that is, more than 1,600,000 years ago), it is necessary to examine the geologic record. The fossil content of the Earth's sedimentary rocks speaks for the most part of warmer climates than that of today. There appears always to have been a warm tropical belt, with twin cooler poles. Even near the poles, conditions were at most times temperate and apparently ice-free. Geologists once referred to these benign conditions as the "normal climate" of geologic times, but as early as the late 19th century it had become apparent that this rule had to allow exceptions. Nevertheless, the view persisted, and still persists, that the Earth at most times lacked snow and ice and had no extreme cold in the polar regions.

Some governing conditions. In one respect there is clear evidence that climate has not changed radically for more than 3,000,000,000 years. Metamorphic rocks of this age

in the Precambrian shields appear to contain metasediments that were originally deposited by torrential streams. Running or standing water appears to have been present on the planetary surface in all subsequent epochs. If so, and assuming that atmospheric pressure and the physics of water have not changed, temperatures in the range of 0° to 100° C must have pertained. Since, moreover, simple forms of life evolved in the oceans of early Precambrian times, a more realistic estimate of temperatures may be 0° to 50° C. Present-day temperatures at the surface average 15° C.

Nevertheless, early climates cannot be compared to modern climate with any confidence because other external controls must have been very different. For example,

Variables affecting climate

(1) The early atmosphere was different in composition from that of today. In particular it lacked oxygen and hence ozone. Powerful ultraviolet radiation reached the Earth's surface, inhibiting terrestrial life and guaranteeing an extremely active chemistry in the lower atmosphere. Free oxygen and ozone entered the system later in Precambrian times, as life in the oceans evolved; but the land surfaces were largely naked. This condition held until about 440,000,000 years ago (the Late Ordovician epoch).

(2) The distribution of land and sea was radically different. Vast crustal changes have occurred, such that the physical geography of the planet came to resemble that of the modern Earth only in the most recent 66,000,000 years (the Cenozoic era).

(3) The positions of the geographic and magnetic poles have both shifted relative to the distribution of land masses (or vice versa) throughout geologic history. Thus the south geographic pole migrated into the Antarctic continent more than 100,000,000 years ago, approaching its present position about 70,000,000 years ago. In addition, the magnetic polarity of the Earth has repeatedly reversed itself (a phenomenon that has vital importance for the climate of the upper atmosphere and is also useful in the dating process).

(4) The rate of spin of the Earth about its polar axis, which determines the length of day, has decreased from 425 days per year about 500,000,000 years ago to 365¼ days per year today. Hence days have become longer. This rate of spin determines the Coriolis parameter (see above *Wind*), one of the key controls of the circulation of atmosphere and ocean.

(5) The Sun itself, the source of virtually all the energy in the atmosphere, has gradually become hotter, so that the solar constant (the power per square metre of the incoming solar radiation) has increased throughout geologic history. Heat released from the Earth's interior (very small by comparison) has decreased during this period.

Because these are all factors that control or influence modern climate, ancient climates cannot be expected to have resembled modern climate. Moreover, because these variables have unknown values, reconstruction of ancient climates must rely not on theoretical deduction but on empirical evidence from the geologic record.

The sedimentary record. Deductions can be made about the climatic significance of certain classes of sedimentary rock. These include calcareous rocks (limestones, marbles, marls), arenaceous rocks (sands, sandstones, quartzites, conglomerates), carbonaceous rocks (coals, oil- and gas-bearing layers), red beds (assemblages of red and yellow sandstones, marls, clays, pebble and boulder beds), evaporites (salt, potash, gypsum, certain classes of limestone), and glacial deposits (morainic materials, including diamictites, tills, and outwash fans). Inferences about the climatic meaning of such rocks depend on the lithology of the materials, the known association of such materials with present-day climates, and the fossil biota they contain, if any.

Calcareous rocks. Deposits of calcareous rocks are widespread in the sediments of the entire geologic record. They occur as much-altered limestones in the Precambrian record, where they sometimes appear as crystalline marbles. They are also common in most later periods but are especially widespread in the Carboniferous (360,000,000 to 286,000,000 years ago), Jurassic (208,000,000 to 144,000,000 years ago), and Cretaceous (144,000,000 to 66,400,000 years ago) periods, often in richly fossiliferous forms. In the modern world calcareous sediments appear to form primarily in warm temperate or tropical seas, though foraminiferal oozes (formed from empty calcareous shells) occur even in seas in high latitudes. This modern preference for lower latitude sites, together with the richness of the marine macrofossil record, which is dominated by species typical of warm seas, leads to the view that calcareous rocks speak of warm conditions.

This view is reinforced if, as is often the case, the fossils present include corals. Corals are today largely confined to subtropical shorelines, typically in the 20°–25° C sea temperature range (with temperatures below 18° C fatal to some of the reef builders), and to waters with a salinity of 2.7 to 4.0 percent. Coralline limestones from the late Paleozoic era (*c.* 350,000,000 to 245,000,000 years ago) and the Mesozoic era (245,000,000 to 66,400,000 years ago) are found today in high-latitude outcrops. Thus, even when corrections for polar shift and continental drift are made, it is apparent that warm temperate conditions must have been present in high middle latitudes of both hemispheres during those times.

Climatic implications of coral growth

Arenaceous rocks. Arenaceous rocks are rich in silica and are often made up of fragments of preexisting rocks, implying the breakdown of continental surfaces by processes of rapid denudation. They are widespread in the sedimentary record. These sands, sandstones, and quartzites (the indurated form of sandstone) are usually deposited near shorelines, where their presence says little about climate. However, they may also be associated with specific bedding features that argue for torrential runoffs (deltaic structures, such as the Catskills Delta in the northeastern United States, are one example). Gravel sheets and boulder beds may point up the vigour of the erosion. In a few cases, it has been possible to estimate rates of erosion and from these to make inferences as to temperatures and precipitation. On the whole, however, the sandy rocks of the continents have not revealed much about the climatic history of the Earth.

Carbonaceous rocks. In contrast to the arenaceous rocks, carbonaceous rocks speak volumes, for they are derived from abundant living remains. The most dramatic evidence comes from the widespread occurrence of coal seams in rocks dating from the Carboniferous period onward. These coal deposits clearly represent the remains of forests, chiefly in wetland habitats (where anaerobic conditions prevented oxidation of the wastes). In many cases, the genera and even species of the dominants can be determined from macroscopic fossil contents. Land vegetation first became significant in the Devonian period (408,000,000 to 360,000,000 years ago), but it was in the Late Carboniferous epoch (320,000,000 to 286,000,000 years ago) that the first great development of wetland forests occurred. Forests of gymnosperms (*e.g.*, cycads, conifers, and seed ferns) flourished in the swamplands of coastal plains and in the floodplains of great rivers. Again the evidence is in favour of warm, humid conditions, even in relatively high latitudes. The drier land surfaces appear to have remained naked, however. The coal measures of many regions are intercalations of coal seams within sandy or silty materials washed into the wetlands off barren land surfaces during periods of marine transgression.

Climatic implications of coal deposits

Coal deposits occur in Mesozoic and even Tertiary (66,400,000 to 1,600,000 years ago) rocks, but they contain species that suggest cooler conditions. In the modern world, the most extensive swamp areas in which carbonaceous materials accumulate are in middle and high latitudes. It is therefore unsafe to assume that Mesozoic and Tertiary coals and lignites imply warm climates.

The widespread occurrence of petroleum and natural gas in sediments cannot readily be interpreted in climatic terms, because they appear to have originated primarily from unspecified marine biota. Their abundance is consistent with the view that ancient seas and oceans were biologically productive, and hence probably warm and nutrient-rich; but this consistency does little more than reinforce conclusions drawn from other sources.

Red beds. On all continents, and from many geologic epochs, widespread accumulations of red and yellow rocks

can be found. These red beds are equivocal in the evidence they yield. Massive red quartzites of Precambrian age and similar deposits from the Devonian and Carboniferous periods, from the Triassic period (245,000,000 to 208,000,000 years ago), and even from the Tertiary all appear rich in hydrated iron oxides (accounting for the colour); they sometimes, especially the ancient rocks, also contain partially weathered feldspars. Because of their false bedding, it is clear that some of the red beds resulted from wind deposits; others appear to be associated with alluvial fans (fan-shaped accumulations of sediment deposited by streams draining from mountains to adjacent plains) or with the desiccation of former lakes. Whether deposited by wind or water, these beds appear to have accumulated in inland basins, with no discharge to the sea, as in modern desert areas. Thus, it is often assumed that red bed assemblages imply warm desert conditions. The sparse fossil record (totally absent in the older sediments) usually gives no firm clue as to the climate. On dynamic grounds, it is reasonably certain that deserts have always existed in continental subtropical and tropical areas, so that the abundance of wind-deposited materials and the lack of drainage to the sea are unsurprising.

Climatic implications of duricrusts

In a different category are the duricrusts: hardened, dehydrated crusts formed at or near the Earth's surface. Duricrusts with high proportions of iron oxide can be found in Australia and sub-Saharan Africa. Many parts of these continents have remained above sea level for enormous periods, and the accumulated weathering layer, known as the regolith, may be many metres thick. Some of these ancient regoliths are hard enough to have resisted deflation and sheet erosion. Some appear to be laterites, layers of soil with a porous, claylike texture. Products of rock decay, laterites are formed under warm, humid conditions. Ancient laterites are mostly of Tertiary date, but some may have originated in the Triassic. In some areas they occur where laterization of the weathered material is no longer possible, providing evidence of climatic change. In other regoliths—even in rocks of Precambrian date—it is possible to detect buried layers of soil, or paleosoils, whose composition and structure may reveal climatic inferences.

Evaporites. Thick accumulations of common salt, potash, gypsum, and certain kinds of limestone indicate that rapid evaporation off marine lagoon or outlet-free lake basins has occurred. Such materials accumulate today on desert shorelines and in inland basins (*e.g.,* Great Salt Lake, Aral Sea, Caspian Sea, Lake Eyre). Their presence in ancient sediments points clearly to dry, warm conditions. They are especially common in Triassic sediments but have been deposited in many epochs in differing areas.

Glacial deposits. Because glaciation is still in progress and because there are very recently deglaciated surfaces, chiefly in North America and Eurasia, geologists have a detailed knowledge of the lithology, morphology, and genesis of typical glacial deposits. These include till, or ground moraine (unsorted assemblages of pebbles and boulders that are typically unrounded by water transport and are embedded in a clay or silt matrix); various fluvioglacial sands and diamictites; morainic materials; occasionally windblown sands, often with dune formation; and in some areas (though not of direct glacial origin) windblown loess deposits. Sea and lake ice may raft large boulders and other coarse material (such as faceted sand grains), eventually depositing them far from the margins of continental or alpine glaciers. Finally, glacial ice erodes the surfaces across which it moves, leaving striations and molded rock forms parallel to the direction of motion.

Ancient sediments and surfaces have been found to display some of the above characteristics, providing evidence of past cold conditions. Both tillites (indurated tills) and ice-rafted boulders in marine sediments have been described from a number of geologic epochs. In most cases, however, the identification of such evidence with glacial climates is controversial, because other modes of origin can be adduced.

Nevertheless, it is widely accepted that prolonged cold glacial intervals occurred long before the well-known glaciations of the Pleistocene epoch (1,600,000 to 10,000 years ago). The Precambrian record is too shattered by processes of metamorphism for easy interpretation, though episodes of Proterozoic (2,500,000,000 to 540,000,000 years ago) glaciation have been demonstrated. (The celebrated Gowganda tillite is of this age.) An Infracambrian ice age, about 540,000,000 years ago, is widely accepted, as is another in the Ordovician period (505,000,000 to 438,000,000 years ago). There is also no doubt that a major and probably prolonged (perhaps 10,000,000 years) ice age occurred about 280,000,000 years ago between the Late Carboniferous and Early Permian epochs. Widespread glacially striated surfaces, covered in part by Permo-Carboniferous tillites and erratic boulders, have been exposed in South Africa and Australia. Permo-Carboniferous tillites have also been identified in several areas that must have been located in the high southern latitudes of Gondwanaland, the ancient protocontinent composed of the landmasses of the Southern Hemisphere.

Glacial episodes

Uncertainty remains, however. Because glacial deposits are thin and are readily removed by subsequent erosion, the surviving record is desperately inadequate to provide details. Recent attempts at synthesis have even questioned whether it is safe to conclude that glacial ice was ever absent from former polar regions. Moreover, there may be no surviving evidence of some glacial episodes.

Summary of pre-Cenozoic climates. The scattering of equivocal evidence provided by sedimentary records reveals little about climates more than 540,000,000 years ago (Precambrian time). It is clear that, in order for extensive sediments to accumulate in lakes and seas, strong erosion must have occurred, so temperatures must have been in the range in which water is liquid; but more precise figures cannot be determined. There are evidences of early glaciations, but, like more recent events, these appear to have been relatively short-lived.

For the roughly 500,000,000 years between Precambrian time and the Cenozoic era, during which time the basic geography of the planet changed as the result of continental drift and mountain-building phases, the following generalizations appear to be supported by reasonable evidence:

(1) In general, the Earth possessed a usually warm and moist climate, with latitudinal zonations. The equatorial belt was at least as warm and humid as it is today, but the polar caps lacked ice, the seas were open, and high-latitude land vegetation (as it evolved) appears to have responded to cool temperate conditions. The equator-pole temperature gradient (which drives the atmospheric general circulation) was usually near half today's values. Deserts existed in the continental areas, probably in subtropical latitudes, but at certain times they became more extensive.

(2) Strong increases in poleward temperature gradients occurred at least twice, once at the outset of the Cambrian period (about 540,000,000 years ago) and again in Permo-Carboniferous times. Allowing for continental drift, these episodes appear to have been effective in creating cool polar conditions, with westerly winds around the polar caps. Evidence from the fossil record also suggests that the entire globe was relatively cool and dry from 320,000,000 to 208,000,000 years ago, during the Late Carboniferous, Permian, and Triassic periods. The fossil record then indicates that the Earth warmed substantially during the following 140,000,000 years (the Jurassic and Cretaceous periods). The Cretaceous period especially appears to have been the heyday of world climate, with calm, equable conditions. It was a time of expanded ocean surface, with extensive shelf seas. Mean annual surface temperatures exceeded present-day values by about 6° C, with no polar ice caps.

The Jurassic and Cretaceous warming trend

Summary of pre-Pleistocene Cenozoic climates. As is widely known, the Cretaceous period came to an abrupt end about 66,000,000 years ago with what appears to have been a catastrophic event, possibly asteroid impact. There were massive extinctions of many forms of life, perhaps because of rapid cooling induced by stratospheric dust veils that reduced solar radiation heating of the Earth's surface, allowing freezing temperatures to occur at sea level over much of the planet. (This hypothesis has not yet been substantiated, but it has led many scientists to believe that the smoke and dust produced by explosions in a nuclear war could cause similar cold, semidark conditions

and that this so-called nuclear winter could also result in widespread destruction of plant and animal life.)

Whatever the nature of the catastrophe that preceded it, the early Cenozoic era seems to have continued the warm, fairly moist conditions of the mid-Cretaceous. The land surface became covered with dense forests of higher plants, including most of the genera that are typical of today. These forests extended to the land areas near the poles of both hemispheres, which were close to their present positions. (The fossil remains of stumps and embedded roots of trees in the so-called Arcto-Tertiary forest are exposed in situ on two of the northernmost islands of Canada, Axel Heiberg and Ellesmere.) Since the continents had by this time assumed approximately modern latitudes, the zonal divisions typical of the modern world—high- and mid-latitude forests, arid zone, and tropical rain forests—begin to appear in the fossil record.

Oceanic and atmospheric cooling in the Cenozoic

Evidence from deep-sea sediments and Antarctic sites, however, shows that quite early in the Cenozoic there began a slow, intermittent cooling of the world's oceans, both at the surface and in deep waters (see Figure 48). There was an especially sharp decrease in temperature at the outset of the Early Oligocene epoch (36,600,000 to 30,000,000 years ago). Renewed and more profound cooling began in the Middle Miocene epoch (16,600,000 to 11,200,000 years ago). The cooling appears to have been most pronounced in the bottom waters. Thus was introduced the familiar modern fact of cold deep ocean water and floor, which is still of immense importance in the mechanics of climate.

There is also evidence of profound atmospheric cooling in Antarctica, whose thick ice sheet still covers almost the entire continent. Analysis of two cores extracted as part of the Deep Sea Drilling Project (a research program undertaken by several major U.S. oceanographic institutions from 1968 to 1983) has revealed the existence of diamictites and other sediments on the Antarctic shelf about longitude 76° E and latitude 66°–68° S. Magnetic polarity dating assigns these glacial sediments to the Early Oligocene epoch and possibly to the Late Eocene epoch (43,600,000 to 36,600,000 years ago). The evidence suggests that a large glacier complex was present at those times, the ice extending northward 140 kilometres beyond its present limit. The deposits also contain a leaf from a southern beech tree (*Nothofagus*), indicating that in warmer phases an Antarctic forest had been established and that a forest could be reestablished on recently exposed glacial deposits. There is much similar evidence to show that the Antarctic continent was partly or extensively glacierized from the Oligocene to modern times, with the ice sheet reaching its maximum extent 6,000,000 to 5,000,000 years ago during the Messinian age of the Late Miocene epoch (11,200,000 to 5,300,000 years ago). According to present opinion the repeated growth and collapse of the Antarctic ice sheet caused sea-level fluctuations of 80 to 100 metres.

Climatic asymmetry

This summary of Cenozoic climates suggests that the climatic asymmetry of the modern world may date to antiquity. Today, the Northern Hemisphere has warmer temperatures in all latitudes and less glacial ice than the Southern Hemisphere (the area of the Greenland ice cap is only 14 percent that of the Antarctic). There are corresponding differences in circulation of both atmosphere and ocean, the latter being much influenced by the relative absence of land barriers in the Southern Hemisphere. These contrasts may also have existed during the late Cenozoic. The earliest record of Northern Hemisphere alpine glaciation (in Alaska) is on the order of 10,000,000 years ago, considerably later than the Oligocene dates claimed for the Antarctic. The West German climatologist Hermann Flohn has argued persuasively that there was a protracted period (5,000,000 to 3,500,000 years ago) in which the Arctic Ocean remained ice-free while the Antarctic was glacierized. This is disputed, however, by scientists who maintain that the chief mode of sedimentation in the Arctic Ocean has been glacial ice-rafting since at least the Late Miocene (with icebergs adrift in the central ocean). Presumably, therefore, the Greenland ice cap dates to Miocene times. The recent dating of Antarctic glacierization to early Oligocene times, and perhaps beyond, does suggest, however, that Flohn's unipolar glaciation may have existed at an earlier time.

The Cenozoic thus appears as the period in which the world began to assume its modern appearance in at least four ways: (1) the emergence on land of climatically adapted vegetation zones, or biomes, with the flowering plants providing a continuous cover in all but the arid zone (which was always approximately subtropical in latitude); (2) a cooling toward the present climatic regime in which there is extensive glacierization on land in both polar zones, with tundra and cold temperate forest along the subpolar margins; (3) a cooling of the oceans, especially in the Early Oligocene and Late Miocene epochs, with

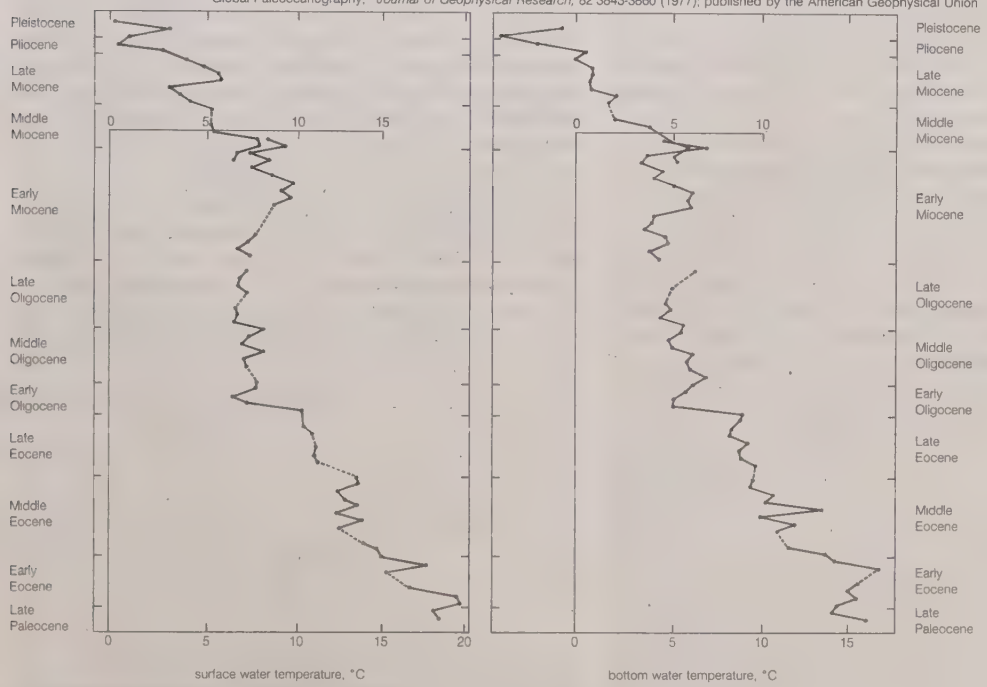

Figure 48: Temperature fluctuations of (left) ocean surface waters and (right) bottom waters. Data based on oxygen isotope analysis of cores from three sub-Antarctic sites.

the establishment of permanently very cold deep waters and ocean floors worldwide; and (4) the establishment of climatic asymmetry between the hemispheres, especially as regards the extent and magnitude of land glacierization.

PLEISTOCENE CLIMATIC CHANGE

The Ice Age

The cooling manifested in the middle and late Cenozoic led about 1,600,000 years ago (a precise date cannot be specified) into the remarkable epoch in which human beings slowly became the ecological dominants of the Earth, the Pleistocene. For almost a century it was believed that the Pleistocene epoch—often called the Ice Age in older literature—saw repeated expansions of ice sheets on the continents, with warm intervals during which the ice receded between the glacial episodes. Stratigraphic evidence, such as the mapping of moraines and till sheets with fossil soils and warm plant and animal assemblages sandwiched between them, suggested that there had been four glaciations of parts of Europe and North America, with four interglacial intervals. The Holocene epoch, which follows the Pleistocene and which constitutes the last 10,000 years to the present, was seen as the fourth of these interglacials, the ice being expected to return. The Holocene was designated separate from the Pleistocene because it encompasses the entire history of human civilization and is the epoch in which human beings overrode all competing lifeforms, but it differs in no other significant way from the interglacial phases of the Pleistocene.

This comfortable account of four glacial and four interglacial episodes was shattered in the second half of the 20th century by the flood of new evidence introduced by a variety of new observational techniques. Among the new sources relevant to the reconstruction of past climates are: (1) the establishment of reasonably firm dating techniques that make possible more useful inferences from sedimentary and other records; (2) the growth, following a suggestion of the American chemist Harold C. Urey in 1947, of the study of stable isotopes of oxygen, hydrogen, and carbon in natural systems, and the realization that these isotopes could yield invaluable evidence of climatic variation; (3) the organization, initially by a small group of individuals from several disciplines, of systematic observations of the isotope record in glacial ice, ocean sediments, tree tissues, and ancient groundwater (including cave deposits); (4) the remarkable Deep Sea Drilling Project and its offshoots, which have yielded, with international collaboration, an immense array of sediment cores drawn from areas of the world ocean floor likely to yield direct evidence of climatic variation; and (5) the growth of paleolimnological and paleoecological studies of cores containing lake sediments and peat accumulations, chiefly by applying palynological analysis (the study of pollen content) to the record, mainly but not exclusively in Holocene sediments.

Radiocarbon dating

Dating techniques. There are three main methods used for dating geologic materials. One is through carbon-14 or other radioisotope analysis. Because radioactive elements decay into daughter products at known constant rates, unaffected by outside conditions, scientists can calculate the age of a material by measuring the ratio of original element to daughter product in the sample. A second dating technique involves geomagnetic polarity. Over the Earth's lifetime the polarity of its magnetic field has reversed many times. These reversals occur everywhere at the same instant. Thus, by studying the magnetic alignment of iron oxide particles, which depends on the direction of the Earth's polarity at the time the particles solidify, it is possible to establish the age of a material in relation to the known record of reversals. The third technique analyzes visual annual bands, such as tree rings, varve deposits (annual layers of sediment formed in lakes by glacial meltwater), and in some cases ice layers resulting from the seasonal thawing and freezing of glaciers. Occasionally, materials can be dated by determining their relative position to well-known, identifiable bands of sediment left by volcanic eruptions or periods of eolian dust depositions.

Oxygen isotope analysis. Once a sample has been dated, the climatic signal is then extracted in a variety of ways. For the Pleistocene epoch, it has been the application of oxygen isotope analysis to ocean sediments that has yielded the best results. Oxygen has two main stable isotopes, ^{16}O and ^{18}O, and the waters of the ocean contain both. The ^{18}O is heavier than the more abundant ^{16}O because it has two extra neutrons in each nucleus. Evaporation favours water containing the lighter ^{16}O. The result is that atmospheric water vapour has a measurable deficiency in ^{18}O. Condensation, however, tends to reverse this process, so that the vapour is still more depleted in ^{18}O, especially as temperatures fall (as they do when vapour is carried upward by convection or poleward in atmospheric disturbances). As a result, precipitation of the vapour falling in cold polar or cold temperate latitudes has a marked deficiency in ^{18}O, and the water remaining in the ocean is correspondingly enriched in ^{18}O.

The $^{18}O/^{16}O$ ratio, and hence $\delta^{18}O$ (the deviation, in parts per thousand, between the ratio of the sample and a standard ratio, usually that of standard mean ocean water or of a fossil belemnite known as PDB), is readily measured in research laboratories and can be used to analyze cores from ocean sediments, ice sheets, tree trunks, speleothems (stalactites and stalagmites from caves), and any other relevant material. Similar stable isotope techniques are applied to hydrogen and carbon. The carbon isotope ratio has been of special interest in tree-ring analysis.

In the case of ice cores, the $\delta^{18}O$ record is assumed to yield information about the temperature of the evaporation–condensation sequence that preceded the deposition of the material being analyzed. Suitable calibration curves are well established, though their use is actually quite complicated. Excellent records have been analyzed from Antarctica, Greenland, and some small Canadian ice sheets.

The climatic interpretation of marine sediments relies chiefly on the fact that much of the accumulated material consists of the solid remains (tests) of microorganisms. These may originally have been either shallow-water plankton or benthic species living near or on the ocean floor. In either case, the tests provide information about the $^{18}O/^{16}O$ ratio of the water that supported them, although not in unmodified form; the two isotopes are incorporated into the tests in a temperature-dependent fashion. Thus, ocean floor oozes, which under the microscope can readily be separated into their constituent organisms, contain a record of the local temperature of the original habitat of the species concerned (surface- or bottom-dwelling). Certain indicator species have been standardized for such analyses. In addition, the fact that the ice contained in continental ice sheets is poor in ^{18}O has meant that throughout the Pleistocene epoch ocean water has been enriched in ^{18}O at times of high ice volume. In other words, the oxygen isotope ratio record from the ocean sediments can also be used as a measure of the amount of water withdrawn from the oceans to lie on continental surfaces as ice. Clearly this withdrawal should also appear as changes in sea level (another frequently cited indicator of glacial/interglacial climatic contrasts).

Relation between oxygen isotope ratios and ice volume

Figure 49 shows a record of oxygen isotope deviations in sediments from an equatorial Pacific core spanning the past 850,000 years. The geomagnetic polarity reversal, at 730,000 BP, anchors the time scale. The numbers directly above the curve indicate the different stages of

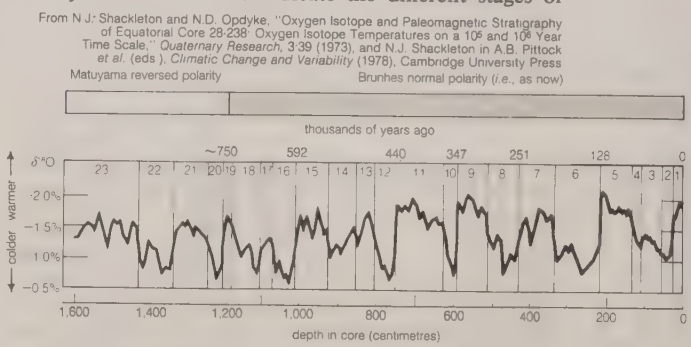

Figure 49: Oxygen isotope deviations in sediments from an equatorial Pacific core (V28-238, at roughly 1° N, 160° E), showing sharp and rapid alternations of high and low volumes of continental glacial ice (see text).

the climatic sequence. Odd numbers, corresponding to stages with more negative values of $\delta^{18}O$, mark times of low glacial volume. Even-numbered stages, or those with higher values of $\delta^{18}O$, mark cold glacial phases. As this and other records show, there appears to have been a high volume of glacial ice on land—*i.e.*, withdrawn from oceanic waters—many times in the past 3,000,000 years. Between these glacial episodes came shorter phases of low glacial ice volume, presumably because of warmer climates.

Glacial and interglacial phases. Using oxygen isotope analysis and other sources, climatologists have been able to piece together an extraordinarily detailed record of the Pleistocene climates, though much remains to be done. Overall, the record shows that the entire epoch was characterized by fluctuating glacial ice volumes, which were associated with swings of global air temperatures and equivalent oceanic changes (including small but extensive shifts in the temperature of the deep waters in all the main ocean basins). The number of glacial episodes and of interglacials clearly far exceeds the numbers that were once suggested by the study of Pleistocene sediments on land. Unfortunately, the complete history of the earlier glacial episodes on land may never be known because so much of the record was obscured or removed by subsequent glaciations.

The overall swings in planetary temperature between glacial and interglacial episodes have still not been fully determined. Interglacial temperatures as much as 5° C higher than those of today have been inferred from some records. Glacial temperatures on land in the range of 10° to 15° C below current values also have been cited. It is certain that the actual departures were lowest in equatorial oceanic areas and that the largest swings were in high latitudes.

Glacial temperatures

Considerable detail is available for the past 250,000 years. This long interval saw two major glacial episodes, the last of which, called the Wisconsin in North America and the Würm in the European Alps, left most of the available field evidence of glaciation on land surfaces. An interglacial separated the two glaciations, beginning about 130,000 years ago (though there is dispute over this date); it yielded to renewed glaciation at least 80,000 years and perhaps as long as 110,000 years ago. It is usually argued that the start of this warm interglacial interval coincided with a maximum of summer solar radiation in the Northern Hemisphere, which is indeed confirmed by the Milankovitch theory of orbital variations (see below). The evidence also points to an enduring characteristic of the global climate: *i.e.*, that major swings in temperature, such as glacials and interglacials, tend to affect both hemispheres simultaneously and thus are global events.

Figure 50 summarizes an important achievement of Antarctic field research, the analysis of an ice core from the Soviet research station Vostok, yielding a record that spans 160,000 years. Curve A shows the carbon dioxide concentration in trapped air bubbles in the ice as a function of date. Curve B shows the temperature at the time, as derived from $\delta^{18}O$ analysis. The resemblance between the two curves shows that temperature and carbon dioxide concentration went hand in hand through most of the late Pleistocene epoch (though it does not say which is cause and which effect). Also plotted in Figure 50 are curves showing estimated changes in sea level. Curve C, based on $\delta^{18}O$ analysis of an east equatorial core from the Pacific Ocean floor, shows how global sea level may have varied. Sea level was highest at the warmest times, corresponding to small volumes of ice in Antarctica (and in the Northern Hemisphere) and high levels of atmospheric carbon dioxide. Curve D shows the calculated dates of coral terraces, uplifted rapidly over the past 160,000 years or so on the coast of Papua New Guinea, in the Huon Peninsula. The sea-level curves bear strong resemblances to the Vostok data. Thus, there is parallelism between all four pieces of evidence, which are drawn from disparate sources, demonstrating the global nature of major climatic variations.

The global nature of climatic variation

Some uncertainty remains, however, concerning the correctness of the dates used on Figure 50. Figure 51 shows a third long record, extending from 50,000 to 310,000 years ago. It is drawn from borings through a calcite vein, made

Opdyke, "Oxygen Isotope Paleomagnetic Stratigraphy of Equatorial Core 28-238 Oxygen Isotope Temperatures on a 10^5 and 10^6 Year Time Scale," *Quaternary Research*, 3:39 (1973); and J. Chappell and N.J. Shackleton, "Oxygen Isotopes and Sea Level," reprinted by permission of *Nature*, vol. 324, no. 6093, pp. 137–140 (1986), copyright © Macmillan Magazines Limited

of material deposited from percolating surface waters at Devils Hole, an open fault zone in the Great Basin of the United States near the Nevada–California border. In this case, the material was dated using two radioisotope techniques, which gave very similar dates. The chronology is believed to be correct within approximately 3,000 years at the 140,000-year point on the curves.

There is again a resemblance between the Great Basin curve and those in Figure 50, two of which are reproduced in Figure 51. The main peaks and troughs, however, fit closely only if the lines joining them are slanted (whereas they should be vertical if these are simultaneous global events). Termination II, the assumed beginning of the last interglacial, appears to have occurred in Nevada 147,000 ± 3,100 years ago, or 16,000 years before it appears in the oceanic record. Thus, the Great Basin curve calls into question the validity of the dating techniques used for the Antarctic ice and the marine sedimentary records. If the Great Basin chronology is correct, the view that there is a close fit between solar orbital data and temperature needs to be reexamined.

One fact that emerges clearly from these records, and from the earlier work of Willi Dansgaard and his colleagues in Greenland, is the apparent short length of the last interglacial. High temperatures, sea levels, and carbon dioxide content seem to have lasted barely 20,000 years. The period between 110,000 years ago and the culmination of the Wisconsin/Würm glaciation 18,000 years ago was one of predominantly cold conditions and low sea levels, though both sea level and temperature fluctuated rapidly as they sank to their lowest recent levels in 18,000 BP.

Summary of Pleistocene climates. Uncertainties still abound, but a clear view of Pleistocene climate is now within reach. The epoch emerges as an interval of almost 2,000,000 years, during which temperatures were usually below those normal to geologic history and during which polar ice caps waxed and waned. There were many episodes of full glaciation when global temperatures may have been 5° C or more below present values, and perhaps 10° C below more ancient norms. There were, however, other intervals—interglacials or interstadials—of relative warmth, usually with enriched carbon dioxide concentration in the atmosphere. Most warm intervals appear to have been quite short, and they seem to have ended abruptly with a return to colder glacial conditions. These repeated changes (vastly more numerous and more complex than was once supposed) and the general coolness continued a trend clearly visible during the preceding Tertiary period.

The events of the Pleistocene epoch have left a remarkable record in ocean sediments, in the Greenland, Antarctic, and Canadian ice caps, and in certain continental sediments. Modern geochemical and geophysical techniques have made possible quantitative estimates of temperature, sea level, and atmospheric compositional changes. These have been coupled with paleoecological reconstructions of past living communities on land and in the sea. The Pleistocene is the earliest period for which the record is amenable to quantitative methods.

LATE PLEISTOCENE AND HOLOCENE CLIMATIC CHANGE

Evidence bearing on the most recent 18,000 years of Earth history is more diverse and persuasive than that available for earlier epochs. The geophysical and geochemical methods described for the Pleistocene continue to be valuable, but emphasis now shifts toward paleolimnological and paleoecological data (lake sediments and peat deposits, interpreted chiefly for their pollen contents) and the art of climatic modeling. In the 1980s, research was further expanded by the coming together of two quite different traditions, those of field geologists and biologists on the one hand and those of atmospheric scientists on the other. The result has been a remarkable advance in climatic knowledge.

CLIMAP and COHMAP

Two exercises involving leading research figures from many disciplines and several countries have particularly contributed to the fund of knowledge. The acronyms by which they are known are CLIMAP (Climate: Long-range Interpretation, Mapping, and Prediction) and COHMAP (Cooperative Holocene Mapping Project). CLIMAP was an attempt to specify in considerable detail the condition of the Earth's surface, most notably the oceans, at the climax of the Wisconsin glaciation 18,000 years ago; it also included a series of mathematical modeling exercises aimed at defining the atmospheric circulation present at that time. COHMAP is a later exercise designed to unravel the history of deglaciation of North America and Eurasia, the recolonization of the northern land surfaces by plants and animals, and the equivalent changes in the tropics and the Southern Hemisphere. Much of the following discussion is based on information derived from these two studies.

At the time of the late Wisconsin maximum, and for several millennia on either side of 18,000 BP, two major ice sheets, the North American complex and the Fennoscandian ice sheet, covered a substantial part of the northern continents. These must have accumulated during the long, intermittent cooling in the interval following 110,000 BP. Furthermore, because the solar radiation regime at 18,000 BP did not differ much from that of today, the ice sheets must have been inherited from the past. They, nevertheless, imposed their own effects on world climate.

The North American complex included a deep cover over the Western Cordillera, the Laurentide sheet centred on Hudson Bay, and the Greenland sheet (in part linked with the Laurentide by floating shelf ice, also present along the Arctic Ocean flank). Its southern limit on land extended from Puget Sound across the Missouri and Ohio valleys to New England and the Canadian Atlantic provinces. The Fennoscandian ice sheet covered Scandinavia, Finland, much of Britain and Ireland (which had local glaciation as well), parts of the North European Plain, the Baltic states, northwestern Russia, and Belarus. Smaller ice sheets covered the Alps and certain mountain masses in central and eastern Asia. Alpine glaciers were extended in many of the world's mountain systems, including those of the tropics. There was a major expansion of the Arctic Ocean pack ice into the Norwegian Sea, with seasonal ice extending into the Atlantic as far south as a line from Portugal to the Grand Banks off Newfoundland. The southern limit of the cold Arctic water—the oceanic polar front—was pushed far south of its present locus.

The Antarctic ice sheet, then as now the largest glacial mass, was surrounded by a large expansion of the seasonal pack ice belt in the Antarctic Ocean. Alpine glaciation affected the Andes, the southeastern Australian ranges, and New Zealand, but the absence of extensive land removed any possibility of large-scale southern hemispheric glaciation outside Antarctica.

These conditions speak of a world with annual temperatures 5° to 6° C below present values, with averages over and near the ice sheets perhaps 10° to 15° C below. Because of the equatorial shift of the oceanic polar fronts, there were extensive areas of both southern and northern oceans that were 10° C colder than at present. A worldwide drop in humidity and precipitation (with local exceptions) must also have occurred.

Causes of deglaciation and Holocene warming. It is now widely held that the rapid recovery of temperatures after the Wisconsin maximum was caused by variations in the Earth's orbital behaviour. This astronomical or orbital variation theory of climatic change, which was developed in 1920 by Milutin Milankovitch, a Serbian scientist, explains not only the Holocene recovery but also many of the remarkable fluctuations of Pleistocene times. The theory is based on the fact that the orbit of the Earth around the Sun varies in three ways. All of the variations are small, but, especially when they reinforce one another, they are sufficient to cause significant redistributions of solar heating between latitude belts or hemispheres. Because the hemispheres differ greatly in surface properties and heat storage capacity, these orbitally caused variations in the pattern of solar heating are capable of changing global climate. The three modes of variation are the obliquity, or tilt, of the Earth's axis, which varies with an average period of about 41,000 years; the precession of the equinoxes, which refers to the movement of perihelion (the point when the Earth is nearest to the Sun) around the path of orbit and which varies with a period of roughly 22,000 years; and the eccentricity of the orbit, varying with a period near 100,000 years. Elaborate mathematical analysis of these parameters has made it possible to calculate the corresponding changes in solar heating of the Earth over the past 750,000 years.

The Milankovitch theory of orbital variations

These calculations show, for example, that over the past 18,000 years the amount of solar energy reaching the Earth in summer was concentrated in the Northern Hemisphere, reaching a peak of 40 watts per square metre

above 1950 values between 12,000 and 9,000 years ago. This corresponded to an 8 percent increase in northern high-latitude summer heating, enough, it is believed, to account for the wastage of the Fennoscandian and North American glaciers (only Greenland's ice survives today). The winter cooling that compensated for the extra summer heat (orbital changes produce such seesaw effects) was most effective in the subtropical latitudes of the Southern Hemisphere. After 9,000 BP these trends reversed, and the modern world has a solar heating pattern much like that of the late Wisconsin maximum in 18,000 BP. The climatic impact of these changes, as calculated for the COHMAP exercise, is shown in Figure 53.

The right-hand panels of the figure illustrate the main features of the atmospheric circulation over the North American-European region (at 3,000-year intervals) and over the African-Indian Ocean-Australasian area (at 9,000-year intervals). These sketches are based on more detailed originals derived from the application of an atmospheric general circulation model (AGCM) to the conditions applicable at the time, including the solar radiation, the extent of ice cover, sea-surface temperatures, and other boundary conditions. The left-hand panels are COHMAP reconstructions of the measured environmental changes in the two sectors during the past 18,000 years. For land areas these are based primarily on pollen analysis of dated lake sediments, with some data from long peat sequences (a recent synthesis extends back into the last interglacial). The striking northward march of the forest biomes into the glaciated northern landscapes dominates events on land. Also visible is the rapid shrinkage of glacial ice on land: the Fennoscandian ice sheet was almost extinct by 9,000 BP and the Laurentide sheet by 6,000 BP. At sea there was a major reopening of the northern North Atlantic and Norwegian seas as the pack ice front retreated. In addition, as glacial ice melted, sea levels rose, reducing land area in, for example, northwestern Europe and Southeast Asia.

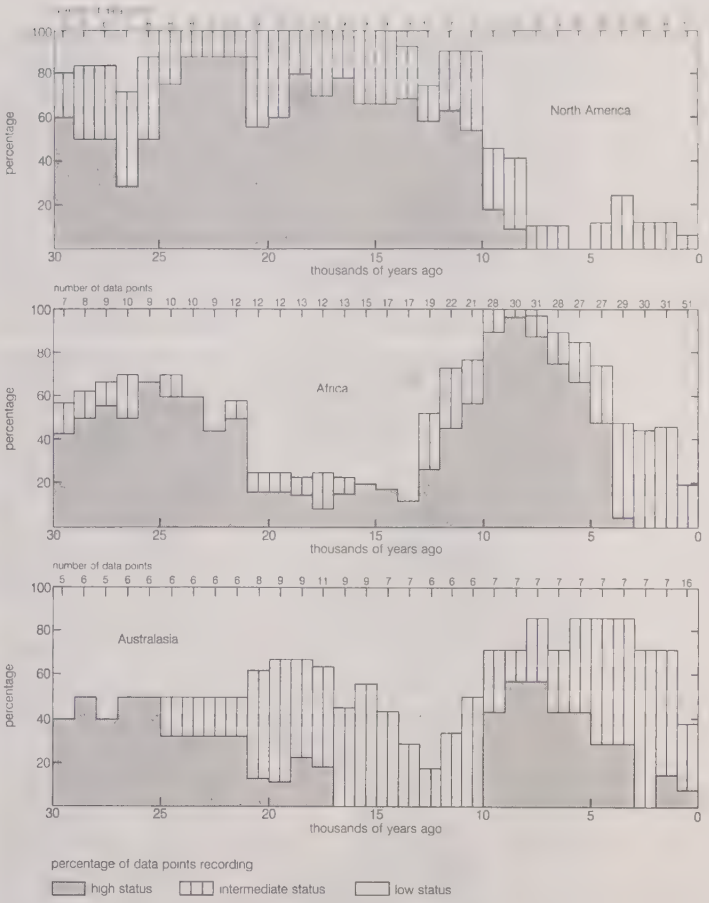

Figure 52: Estimates of percentage of high, intermediate, and low water levels in inland lakes.

From. F.A. Street and A.T. Grove, "Global Maps of Lake Level Fluctuations Since 30,000 B.P." *Quaternary Research*, 12:83-118 (1979), Academic Press

By 9,000 BP summer temperatures and precipitation had risen above present-day values in much of the land area of the Northern Hemisphere. These warm conditions—the so-called hypsithermal interval (or, in older usage, climatic optimum)—remained in place until about 6,000 BP, after which temperatures fell slowly to their present values (with minor irregularities discussed later) some centuries before the Christian era. This period of warmer climate occurred earlier in western North America than in the east, where the shrinking Laurentide ice kept temperatures cool. It also made an early appearance in parts of the Southern Hemisphere. In New Zealand, for example (where the glacial maximum is believed to have preceded that of the Northern Hemisphere by 6,000 to 7,000 years), warmest conditions appear to have occurred between 10,000 and 8,000 BP.

The hypsithermal interval

The Holocene warming was accompanied by far-reaching climatic changes in the arid zone and in the monsoon lands of Africa and Asia. Like the warming, these changes were in response to the orbitally caused changes in the amounts of incoming solar radiation. Geologic data show that rainfall in these areas was especially affected.

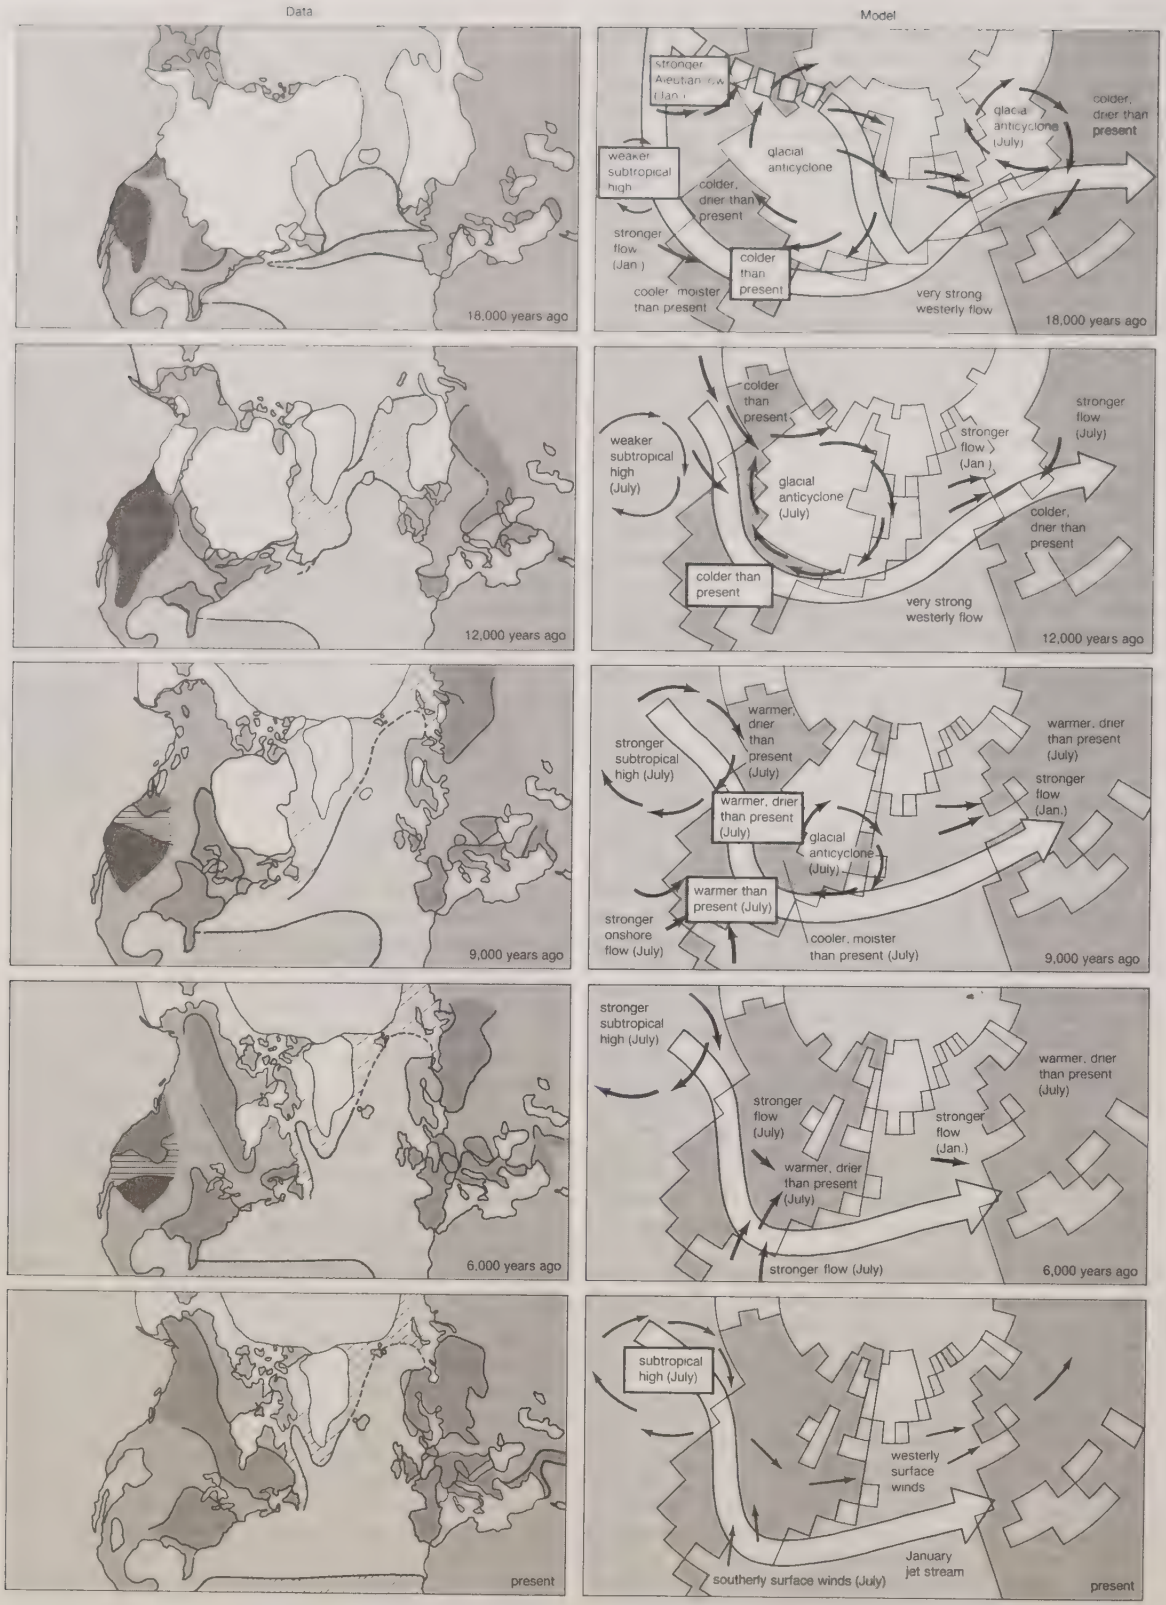
Relative moisture during the Holocene warming

An excellent measure of rainfall in the arid zone is the water level in closed lake basins (many of which are now dry). Figure 52 shows the changes in lake levels (in generalized form) on the chief continents. In North America, where the obstacle of the Laurentide ice sheet and associated anticyclonic circulation drove the main westerly jet stream southward throughout the Wisconsin, lake levels in the western United States (especially the Great Basin) were high until about 10,000 BP, when the ice sheet receded and circulation assumed its modern pattern (with the jet stream entering the continent further north at about 50° N). Because the jet stream steers the cyclonic storms bringing rain and snow, the now-arid southwest was abundantly watered until this northward shift.

African lakes, by contrast, were low in glacial times. After about 12,000 BP, however, they rose to high levels, especially between 10,000 and 7,000 BP, until general desiccation occurred after 5,000 BP. While general cooling affected high northern latitudes at this time, there seems to have been a marked slackening in the monsoon rainfall that fed many of the African lakes. In Northern Africa, in particular, the moist phase of the early Holocene attested to by the high lake levels corresponded to the appearance of lush savannas supporting hippopotamuses and other large animals throughout the present-day Sahara desert. This early Holocene moist phase was widespread elsewhere in the Middle East and other parts of Asia, enabling (as it closed) early human innovators the opportunity to move from hunting to pastoralism and from gathering to arable agriculture.

Research has confirmed that the Milankovitch orbital changes strengthened the monsoonal currents of the Northern Hemisphere during the early Holocene. At the time of the Wisconsin maximum the monsoon was weak, but between 12,000 and 5,000 BP summer temperatures in inner Asia were as much as 4° C warmer than today, making possible the strong monsoon of this period.

The Recent (pre-instrumental) phase. Although climatically inseparable from the Holocene epoch, the time period in which human civilization developed is sometimes referred to as the Recent phase. This phase comprises the past two millennia globally and the past nine locally. A much more secure chronology of events can be compiled for this period, and there is a substantial increase in the body of climatic evidence available. In fact, the volume of evidence is so great that only a short list of the major sources can be presented here. Prior to the 17th century, when instrumental records began to be kept, these sources included: (1) the methods already defined for the Holocene epoch, except for those with low time resolution capabilities (such as the solar orbital data); (2) direct glaciologic and glacial geomorphologic observation, especially in intensively studied areas such as the European Alps and the Scandinavian countries; (3) tree-ring analysis, or dendrochronology, which provides evidence for the past nine millennia in favourable areas; (4) full archaeological evidence; and (5) the vast documentary record, which tends to provide anecdotal or episodic evidence and



includes such sources as records of grape, hay, and grain harvests, logs of harbour conditions, and land-use records. Content analysis has recently sharpened use of some of these sources.

The picture that emerges from the evidence is of a climate quite similar to that of today, yet not discontinuous with that of middle and late Holocene times. The differences that have been demonstrated are often subtle and poorly defined. Many long-term records, such as those for stream flow, can even be interpreted as a form of noise, lacking meaningful pattern. Others have obvious and prolonged fluctuations that deserve mention, but it is usually difficult to establish the geographic extent of these fluctuations, because the record is badly broken in time and space.

One of the most detailed local records is that provided by the pollen analysis of the great peat bogs of northern Europe. During the late prehistoric and early historic phases of the past 6,000 years, these bogs appear to have undergone a number of desiccations (warm, dry summers), revealed in the bog cores as dry, often wooded, surfaces. The dry phases were generally followed by wet conditions in which peat accumulation was rapid. These overlying

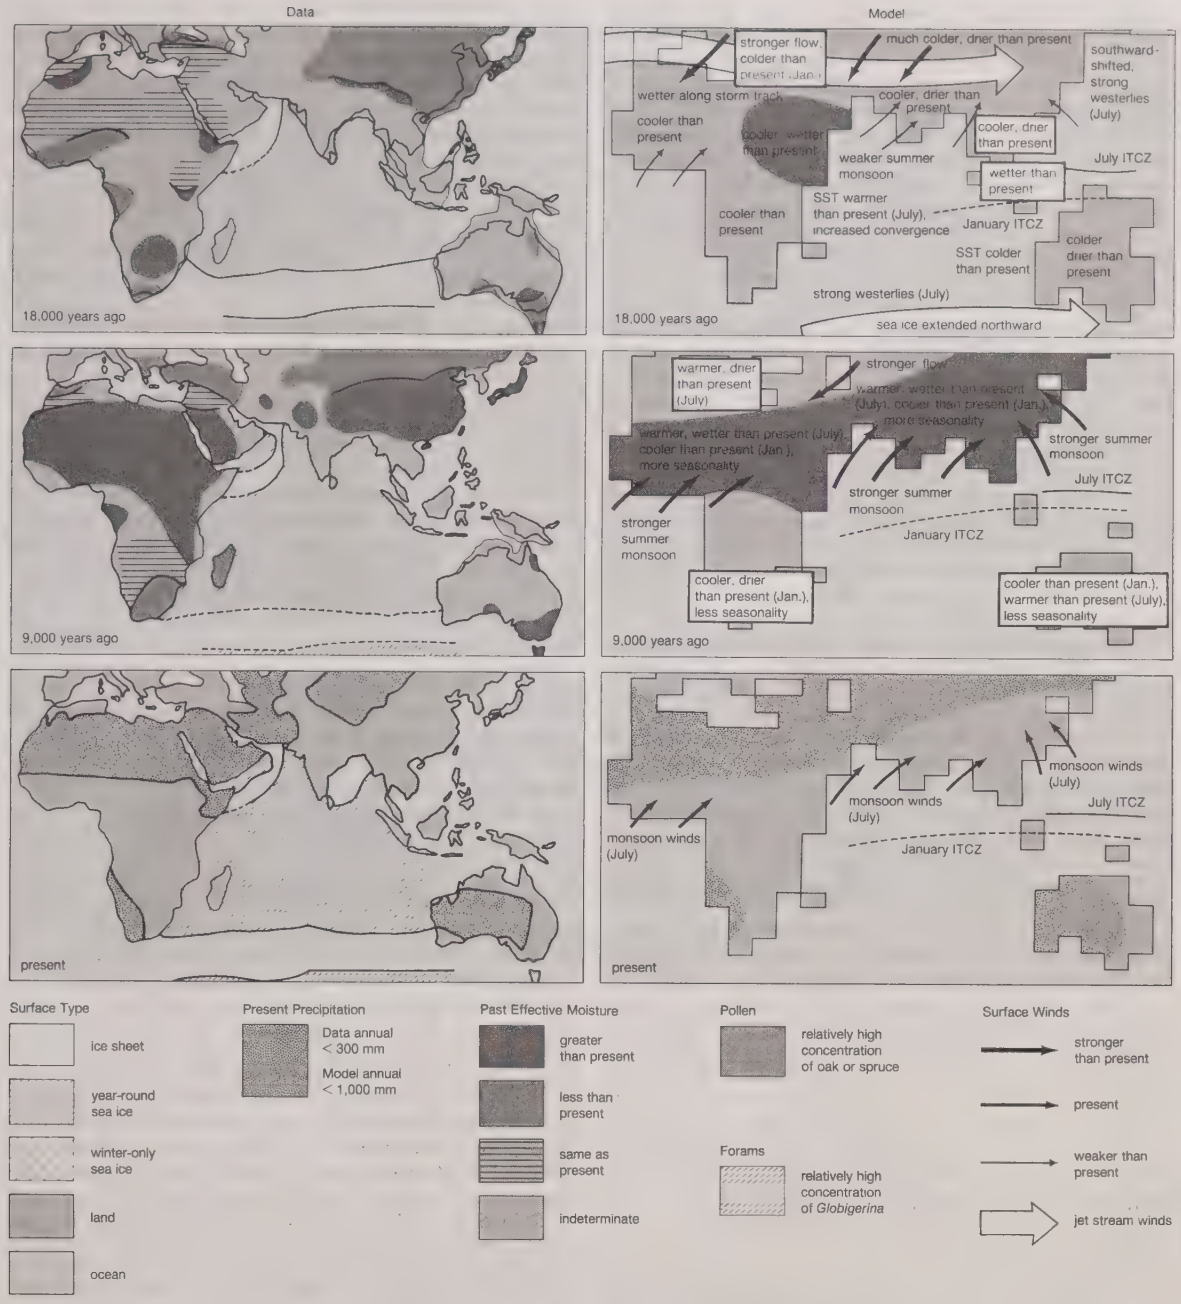


Figure 53: COHMAP reconstructions of (left panels) changes in environmental distributions, based on observed data, and (right panels) estimated changes in climate, based on general circulation model (see text).

From COHMAP Project Members (1988), "Climatic Changes of the Last 18,000 Years: Observations and Model Simulations," *Science*, vol. 241, no. 4869, pp. 1043–1052 (1988), copyright 1988 by the American Association for the Advancement of Science

layers of renewed peat growth are known as "recurrence" horizons. For a long time the analysis of these and other such singularities in the peat and lake-floor record seemed indispensable to the interpretation of the post-glacial climatic record. Today, they are viewed as evidence of minor fluctuations in a record that does not greatly depart from present conditions. Thus, the slight cooling that followed the hypsithermal interval is recognized as spasmodic. Similarly, it is clear that Europe in the period 500 BC to AD 1000, which was crucial to the continent's human settlement, was subject to climatic fluctuations whose sociological importance far outweighed their small magnitude.

The medieval warm period

There is general agreement that from perhaps AD 600 to 1400 European and North Atlantic climates became warmer and probably drier. Evidence of this warming comes from many regions and includes such sources as agricultural records as well as limited pollen, water-level, and macrofossil data. Although the evidence is often rather flimsy, it implies that during those eight centuries temperatures were perhaps as much as 1.5° C higher than those of today. As a result of this medieval warm period, Viking settlers were able to establish thriving colonies in Iceland, Greenland, and Newfoundland. The northern limit of viticulture, which requires sunny, warm conditions, extended farther north than it does today, into northern France and Germany and southern England. In Arctic Canada and Greenland the highly developed Thule culture, which depended on whaling for sustenance, flourished late in the period, until colder conditions made whaling impossible.

Although it is clear that the Middle Ages were characterized by warm conditions, any objective compilation of local records must reveal that no real coherence exists. The climax of the warming occurred at different times in different places, and no region experienced stable, continuous warmth for more than two or three centuries. Alpine glaciers were far advanced in their valleys at the height of the period, and there is much other evidence that confirms the variability of the regime. Outside Europe and the North Atlantic area, in fact, there is little evidence that this warm phase ever took place.

The Little Ice Age

Studies of glacial sediments, tree rings, and written records show that, from the beginning of the 16th century until the mid-19th century, cooler and harsher conditions prevailed in most parts of the world. As with the medieval warm period, the climax of the so-called Little Ice Age arrived at different times in different areas. In general, the Northern Hemisphere, especially North America, the Arctic, and East Asia, seems to have been affected earlier than the Southern Hemisphere. Some conditions appear to have been globally synchronous, but their magnitude varied from place to place. In addition to regional variations, there was increased variability from season to season, from year to year, and from one group of years to the next, so that, for example, central England experienced several of its hottest summers in the 17th century, one of the coldest centuries on record. Some of the effects of the Little Ice Age on human life are reflected in records of crop failures and famines, the abandonment of northern farms and villages, and changes made in sailing routes to avoid advancing ice. Although the main cold phase ended about 1700, the bleak winters and cool, moist summers that characterized the Little Ice Age continued in many parts of the world until as late as the mid-19th century. In 1850, for example, meteorological instrument records show that temperatures were still about 0.7° C below present-day global values.

Contemporary climatic change. Meteorological instrument records survive from as early as the 17th century, but it was not until about 1850 that the number of well-calibrated instrumental records of temperature and precipitation was adequate for statistical analysis. Since then, the data files have accumulated rapidly, and in recent decades reasonable quality control has been achieved by the World Meteorological Organization. The record extends over the entire globe (now observed continuously by a variety of sensors on geostationary or polar-orbiting satellites), as well as upward into the stratosphere, with less-abundant data from the mesosphere.

Temperature fluctuations. Figure 54 shows an estimate of global mean annual temperature changes at the surface from 1860 to the 1980s. The estimates are adjusted to allow for the unequal spacing of data points between land and sea, between mid-latitudes and the polar regions, and between the hemispheres. Data from cities with a population of more than 100,000 have been omitted or adjusted because of the so-called urban heat island effect. (Urban areas are warmer than the surrounding countryside because asphalt, concrete, and other urban surfaces absorb and store heat more efficiently than rural vegetation.) The curves show: (1) an almost linear increase of temperature throughout the record, amounting to 0.7° C since 1860; (2) an irregular sequence in the Northern Hemisphere, where in particular the period 1940–70 showed no increase, or even a slight decline; (3) a much more uniform upward trend in the ocean-dominated Southern Hemisphere; and (4) an especially vigorous warming in the 1980s, the warmest decade in the entire record.

Jones *et al.*, "Evidence for Global Warming in the Past Decade," *Nature*, vol. 332, no. 6167, p. 790 (1988), both reprinted by permission of *Nature*, copyright © Macmillan Magazines Limited

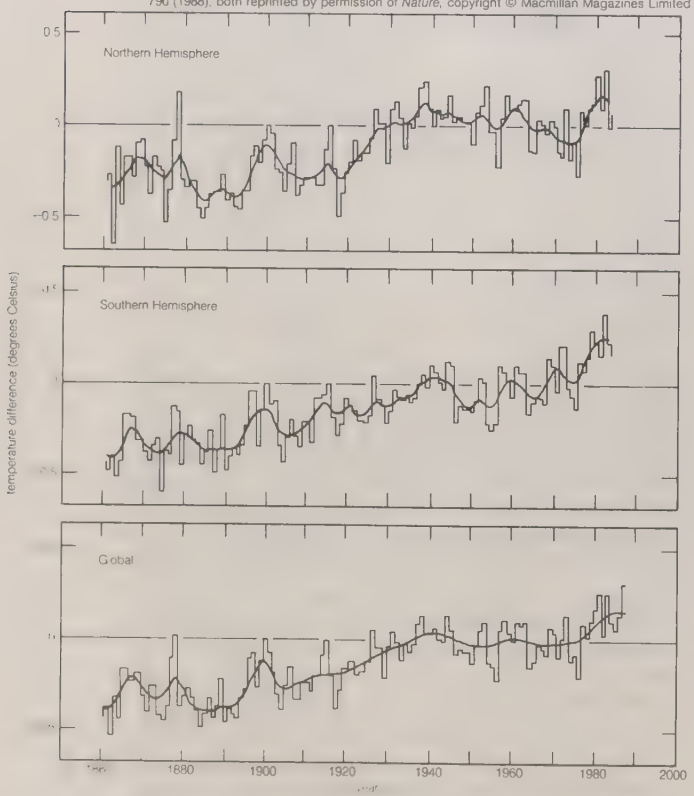

Figure 54: Variation of mean surface air temperature from 1860 to the 1980s.

There have been questions as to whether the effect of urban heating on local temperatures has been truly eliminated from such data. An investigation suggested that as much as 0.1° C of the apparent warming might have been due to this contamination of the record. One similar temperature analysis is believed to have been seriously compromised by urban heating. The self-heating of cities is, of course, a real effect that has had significant economic consequences. On the global scale, however, it is in reality negligible. Unfortunately, this may not be true of its impact on the record.

The contemporary global warming trend

It appears that a real global warming of 0.4° C has occurred in the 20th century and that it accelerated in the 1980s after a three-decade hesitation. If the responsible agent is the greenhouse effect (see below *Climate and life*), the warming is at the lower end of the model-predicted range; higher temperatures might have been expected from the increase in greenhouse gases observed since the 19th century. Greenhouse heating might also have been expected to be concentrated in polar and subpolar latitudes, while, in fact, temperature increases in the Northern Hemisphere have been greatest in a high mid-latitude belt. Many large regions, including much of North America, so far show little or no upward trend of temperature.

Precipitation fluctuations. Precipitation measurements are less amenable to study and in any case are only available on land. Figure 55 shows an analysis of precipitation data from Northern Hemisphere land stations. In each graph the percentile position is relative to frequency distribution, as specified by a mathematical representation. (For example, a percentile value of 0.6 in any given year means that precipitation in that year was greater than or equal to 60 percent of the other annual values.) This analysis shows that little has changed in the equatorial belt since about 1900, but a significant decrease in precipitation has affected subtropical areas (5°–35° N) since 1960. Mid- and high-latitude stations (35°–70° N) show a substantial increase since 1950. Again the effect is nonuniform, large areas—notably Europe—having escaped any obvious change. Studies have also shown that there are marked seasonal differences in precipitation.

In the 1980s there have been many severe droughts, and there is a natural tendency for lay observers to view these as manifestations of the greenhouse effect, several formulations of which predict drought in mid-latitude areas. Although this is a possibility, most authorities agree that the droughts and other fluctuations are expressions of climate's natural internal variability and not of externally forced change. The reasons for such large-scale variability remain unclear, however. Some authorities have argued that variability tends to increase as mean temperatures decrease, so that the possibility of damaging cold extremes is enhanced. Others see the variability as largely random.

Other fluctuations. Two remaining aspects of recent climatic fluctuations (*i.e.*, nonlasting change) that deserve attention are the great African desiccation of the 1960s, '70s, and '80s and the recognition of the El Niño/Southern Oscillation (ENSO) phenomenon as a source of worldwide variability.

Rainfall in Africa has been highly disturbed since the 1950s, especially in sub-Saharan regions. Numerous studies have demonstrated that the generally high values applicable to the 1950s and early '60s gave way to a prolonged

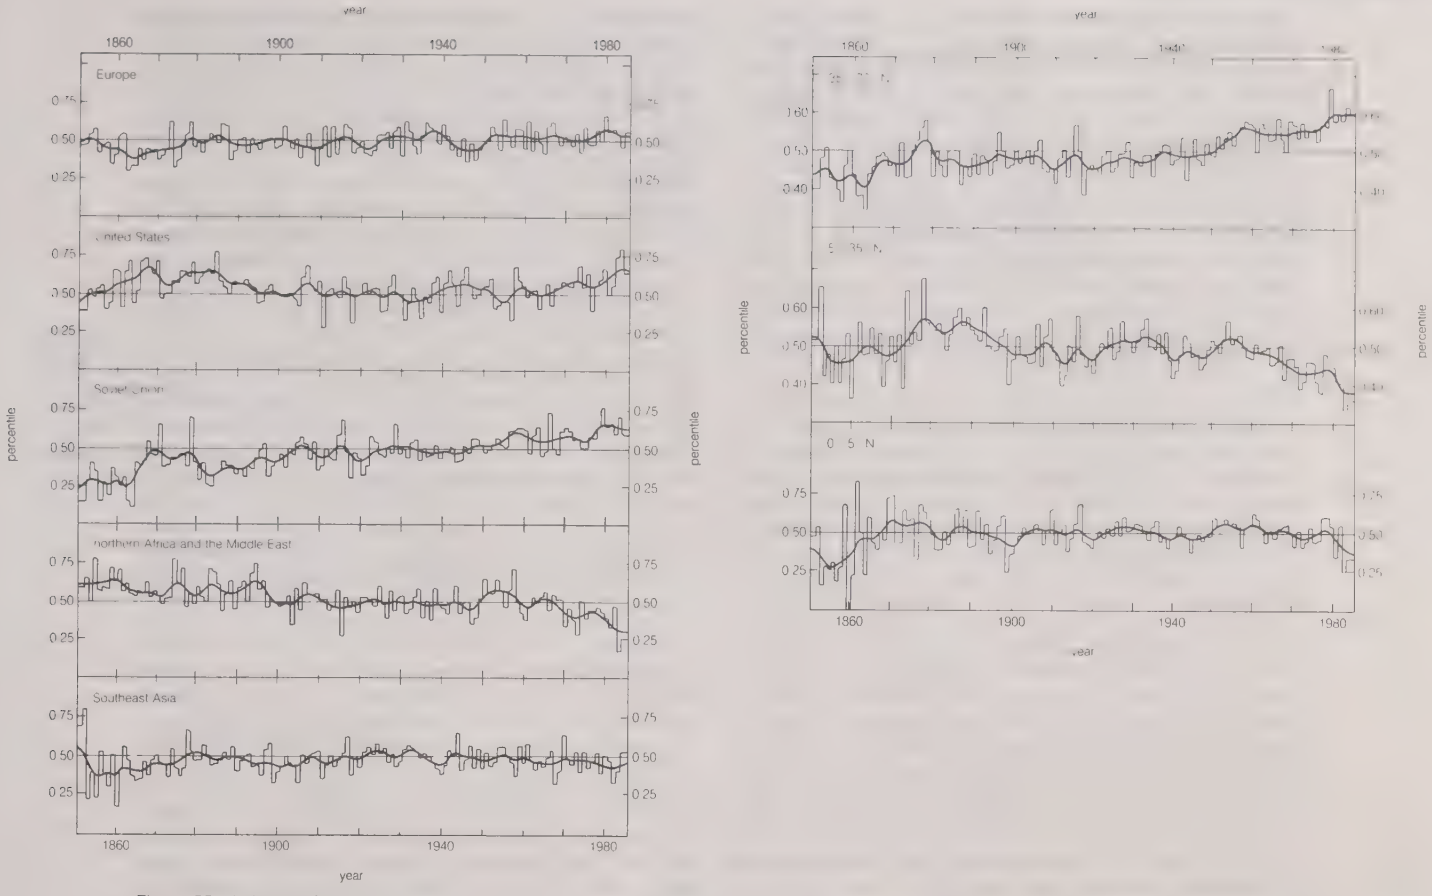

Figure 55: Variation of precipitation over land areas in the Northern Hemisphere from 1850 to 1985 (see text).

From R.S. Bradley *et al.*, "Precipitation Fluctuations Since the Mid-19th Century," *Science*, vol 237, no 4811, pp. 171–175 (1987), copyright 1987 by the American Association for the Advancement of Science

The African drought

desiccation affecting much of Africa, but especially the margins of the deserts. Many countries in the Sahelian and Sudanian zones of North Africa experienced a decline in the already inadequate annual rainfall extending from the early 1960s (when it was abundant) until the mid-1980s. Indeed in some areas the decline had not been reversed by the late 1980s. The impact on food supplies was catastrophic, the effects being exacerbated in Ethiopia, Chad, and Sudan by wars. Over the whole continent the two or three decades of drought were tragically unhelpful to the emerging countries of the formerly colonial area. Although no credible cause can be assigned to this fluctuation, which is not yet fully understood, it has been alleged that human misuse of the land has exacerbated a natural fluctuation.

ENSO events recur every three to seven years. The immediate symptom is the flooding of the normally cold Pacific coastal waters off Peru by warm equatorial water from the west. Such El Niño events are accompanied by changes in the trade winds over the entire Pacific and by large rainfall anomalies over Australasia, India, and parts of southeast Asia (the Southern Oscillation component). Recent research, especially at the Scripps Institution of Oceanography at La Jolla, Calif., has shown that major ENSO events are accompanied by worldwide changes in pressure distribution and by anomalies in temperature and rainfall over North America, Australia, and even Eurasia. The dynamics of these huge teleconnections of climate are not understood, but it is recognized that the year-to-year variability of the modern climate is not a local phenomenon. Moreover, such global interconnections have almost certainly existed throughout the Earth's history.

CAUSES OF CLIMATIC VARIATION

General considerations. Explanation—the identification of causes—is always difficult when one discusses complex phenomena, and climate is very complex. In many ways the atmosphere and oceans function as if they were each closed systems, in which change in behaviour is achieved by purely internal processes. In other ways, atmosphere and ocean are linked, and changes in either may arise from interaction with the other. The climatic system, like most other natural systems, behaves in a nonlinear fashion; that is, it does not necessarily change proportionally in response to a change in external forcing. In fact, the system is choked with feedbacks, both positive and negative, that ensure that this nonlinearity will prevail. It might seem, for example, that local temperatures ought to be controlled by local input of solar energy. In no simple way is this true, however. In the first place, the solar heating triggers a return flow of energy to space (whose dependence on temperature is extremely nonlinear). Furthermore, local temperature is much affected by the transport of heat by ocean currents and the winds—*i.e.*, advection of heat. This is why, for example, Sweden and Hudson Bay have such different climates, in spite of being in the same latitudes. Advection depends in turn on the distribution of solar heating over the whole Earth—and the transport terms in the equations governing atmospheric motion are the reason why these equations are nonlinear. In short, cause can never really be separated from effect in the real world.

Nevertheless, it is reasonable to try to answer the question "Why does climate vary?" To do so, the nature of climate must be considered:

The nature of climate

(1) Climate is best described as the prevailing, and hence expected, sequence of states of the atmosphere (loosely, weather) at a given locality. This definition can be extended to cover regions, hemispheres, or even the entire globe. Climatic change is the shift of this sequence to some new apparently lasting state.

(2) The perceived scope of climate has recently been broadened to include a wider range of measurable parameters (*e.g.*, humidity, particle load, ionization, cloud regime, salinity) and to extend over the entire depth and height of the lower atmosphere as well as the surface layers of the ocean.

(3) Climate may be viewed as part of a larger climatic system, an idea closely related to that of ecosystem. Thus, climate pervades not only the atmosphere and ocean but also the soil, ice masses, lakes and rivers, and the living cover of the Earth—all of which interact with the Sun-driven climate of the atmosphere.

(4) The atmosphere and ocean behave in part as chaotic systems. Although they obey well-known laws, they respond to the laws in a bewilderingly complex way. In spite, for example, of reliably periodic forcing by the Sun and tides, the sea and air appear never to repeat themselves precisely, showing instead a preference for nonperiodic behaviour. Tiny events—in principle even the batting of a butterfly's wings—can amplify into consequences that simply cannot be predicted from the known governing laws.

In some ways the wonder is not that weather and climate are so variable but that regularities do exist behind the complex facade. Nevertheless, it is clear that climate is not just a randomly behaving system. Distinct rhythms and spatial patterns recur, and their signals can be isolated from the noise so evident in climatic statistics. In describing climates, therefore, it is necessary to define not only the mean, modal, or median values of the appropriate parameters, such as temperature, pressure, precipitation, and wind velocity, but also the frequencies and characteristics of the variability, whether it is periodic, nonperiodic, or quasi-periodic. It is vital to recognize that variability within the chosen averaging period is as much part of climate as the mean values of each parameter. Thus the year-to-year variability of rainfall in the Great Plains of the United States or in Sahelian Africa is quite as important (and deserving of explanation) as the mean value of rainfall. In economic terms the variability may be the most important aspect.

Climatic interdependence

Another component of climate requiring definition is interdependence. Correlations often exist between variables as measured locally, for example, between precipitation and humidity or between wind direction and visibility. Teleconnections, or correlations between variables measured in different places, also exist. Finally, a long time series of a quantity such as temperature often displays autocorrelation; *i.e.,* its present behaviour is related to its behaviour at other times. Some of these correlations are of fundamental importance. For example, the frictional drag of the winds on the sea surface, which partly governs the oceanic circulation, depends on the covariance (a measure of correlation) of vertical and horizontal components of the wind and on similar covariances within the sea.

Explanation of climatic change, if it is to be attempted fundamentally, must take these points into consideration. If a popular theory of climatic change, such as the Milankovitch orbital variation theory, can only explain part of the observed change (as is commonly the case), it is necessary to look beyond it, until most of that change is understood. Theory, moreover, should be expressed in quantitative terms. Qualitative guesses no longer appeal (physicists call such guesses "hand-waving"), although they still have a place in the generation of hypotheses.

Identified causes. Theory suggests (and evidence confirms) that the following may be causes of certain types of climatic variation.

Variations in the solar constant. Calculations suggest that a 1 percent change in the solar constant can produce a change in surface global temperature in the range of 1° to 1.5° C. Recent observations show that there have been minor aperiodic changes (±0.2 percent) in the solar constant but none sufficient to account for observed intervening fluctuations (on the order of ±1° C since the Little Ice Age).

Variations in the Earth's orbit. As described above, variations in the Earth's orbit around the Sun can cause variations in the distribution and seasonality of solar radiation, which in turn may result in climatic changes. The orbital variation effect has been identified clearly in the geologic, glaciologic, and biotic record of the past 300,000 years, but it is less successful in explaining climatic conditions dating farther back in time. Orbital variations, moreover, can only be used to explain fluctuations on the order of 1,000 years or more, because all three components—precession of the equinoxes, obliquity, and eccentricity—work on long, predictable time scales. It is generally agreed that the waxing and waning of ice sheets and variations of sea level can be related to these parameters in the past 300,000 years, as can many aspects of Holocene variation, notably the monsoons.

Variations in atmospheric composition. The concentration of carbon dioxide in the Earth's atmosphere is known to have varied greatly in geologic time and also in Pleistocene, Holocene, and Recent times, including the past century. It is also known that times of increased carbon dioxide levels have coincided with times of higher temperatures. Although it is clear that a close correlation exists between carbon dioxide and air temperature, it is still not known whether increases in carbon dioxide cause temperature increases or vice versa. Theory suggests, however, that carbon dioxide (as well as other trace gases in the atmosphere) allows short-wave energy (visible light) from the Sun to reach Earth relatively unobstructed but hinders long-wave energy (infrared radiation) reradiating from the Earth's surface from escaping back into space and that this trapping of energy results in a rise in temperature. Variations in climate during the next century are expected to be dominated by this so-called greenhouse effect.

Relation between carbon dioxide and air temperature

Volcanic dust loading of the atmosphere. Explosive eruptions (*e.g.,* El Chichón, Mex., 1982) are known to introduce material into the stratosphere that can remain in suspension for one to three years. This dust veil can reduce solar input, possibly leading to a fall in temperature. The biggest explosive eruptions (*e.g.,* Mount Tambora, 1815; Krakatoa, 1883; both in Indonesia) are known to have produced marked cooling for a few years after the event. It has been argued that a high frequency of explosive eruptions may account for past cool periods. Such eruptions may also have significantly modified the solar-orbital control of late Pleistocene and Holocene climates.

Variations in the distribution of land and sea due to crustal changes. Mountain building, continental uplift, and the drifting of continents have profoundly influenced world climate. They operate on the scale of geologic periods, requiring many millions of years to complete their effects. An example of a climatic change caused by topographic variations is the creation of the cold deep waters of the ocean, which was favoured by such changes as the opening of the Antarctic Ocean (as continental drift separated Australia and Antarctica), the rise of the Isthmus of Panama, and the closing off of the Tethys, the ancient ancestor of the Mediterranean Sea.

Together, these five theories provide possible explanations for much of the known climatic variation on the global scale and on many of the observed time scales. Yet, for the most part they do so only in a crude way, usually in relation to mean annual global or polar air temperatures, sea-ice and land-ice distribution, the position of oceanic fronts, and other integrators of long-term climatic features. They have little to say, in particular, about the internal variability of climate.

Contemporary areas of research. Meteorologists and geologists recognize, in fact, that major gaps still exist in the explanation of climatic variation. On the geologic time scale, for example, it has proved difficult to explain the approximately 100,000-year recurrence period for the cold, glacial episodes of the Pleistocene. This period resembles that of the dominant mode of the orbital eccentricity of the Earth, but this aspect of orbital variation is thought inadequate to explain the glacial episodes so vividly shown in the deep-sea core record.

Climatic modeling

Very much closer to hand, the numerical modeling of atmospheric behaviour (see below *Numerical weather prediction [NWP] models*) has proved effective in the prediction of weather events as much as five or 10 days ahead, starting from a specified initial state. Such models try to predict actual events but lose that ability quickly as the chaotic nature of the dynamics blurs the outcome. Nevertheless, the models can be modified into atmospheric general circulation models (AGCMs). These AGCMs, which do not start from a specified initial state (the weather of the moment) and which do not predict actual events, can

be used, with specified boundary conditions (such as carbon dioxide content, sea surface conditions, relief features, and continental coastal outlines), to create the statistics of hypothetical climates—including that of the present. Reference was made above to the use of one such model in analysis of the COHMAP results for the Holocene epoch.

AGCMs and their cousins, oceanic general circulation models (OGCMs), can be refined to the point where they predict not only mean temperature, pressure, and rainfall but also the annually repeated seasons and nonperiodic variability. Unfortunately, the several models now operational do not compare well with one another in their predictions of regional detail. They also usually differ from observed fact on this scale to an unacceptable degree, especially as regards precipitation.

The most difficult part of climate to predict is unfortunately the one of maximum economic import—variations from month to month, from year to year, and from decade to decade. Marked and persistent anomalies occur on all these time scales (and have probably existed throughout geologic history), but at present they can be neither explained nor predicted. It is thought that they may be related to such periodic or quasi-periodic fluctuations as the so-called "Chandler wobbles" of the Earth's axis, sunspot cycles, the ENSO phenomenon, and the so-called Julian–Madden waves in the tropical circulation, but until the mechanics of such phenomena are more completely understood, no real theories can be advanced.

Finally, it remains uncertain whether or not the atmosphere–ocean system responds exclusively to physical controls. It is possible that biologic regulation is also at work. The idea that the living cover of the Earth interacts with the atmosphere is well established, but meteorologists and glaciologists have generally seen climate as the control and the rest of the ecosystem as response. In 1972 the British chemist James Lovelock challenged this view when he put forward the Gaia hypothesis. Briefly, the Gaia hypothesis suggests that the climate of the Earth has for eons been modulated—perhaps even controlled—by the biota, which regulates the concentration of atmospheric carbon dioxide and other organically derived substances so as to keep temperature and precipitation at advantageous levels. In effect the Earth is, in Lovelock's most recent restatement (1988), a living organism, with self-regulating processes (homeostasis) capable of ensuring the survival of a life-sustaining global climate. (This matter is discussed at greater length below in the section *Climate and life*.) Lovelock's view has been widely disputed, but it is recognized that the role of life in climate and climatic change cannot be lightly dismissed. (F.K.H.)

CLIMATIC CLASSIFICATION

General considerations

The climate of an area, as previously noted, is the synthesis of the weather conditions that have prevailed there over a long period of time (usually 30 years). This synthesis involves both averages of the climatic elements and measurements of variability (such as extreme values and probabilities). Climate is a complex, abstract concept involving data on temperature, humidity, precipitation type and amount, wind speed and direction, atmospheric pressure, sunshine, cloud types and coverage, and such weather phenomena as fog, thunderstorms, and frost and the relationships among them. As such, no two localities on Earth may be said to have exactly the same climate. Nevertheless, it is readily apparent that, over restricted areas of the planet, climates vary within a limited range and that climatic regions are discernible within which some uniformity is apparent in the patterns of climatic elements. Moreover, widely separated areas of the world possess similar climates, which tend to recur in similar geographic relationships to each other. This symmetry and organization of the climatic environment suggests an underlying worldwide regularity and order in the phenomena causing climate (*e.g.*, patterns of radiation, atmospheric pressure, winds, fronts, and air masses), which were discussed in earlier sections.

Climate classification is an attempt to formalize this process of recognizing climatic similarity, of organizing, simplifying, and clarifying the vast amount of weather data collected by the meteorological services of the world, and of systematizing the long-term effects of interacting climatic processes to enhance scientific understanding of climates. Users of climate classifications should be aware of the limitations of the procedure, however.

Limitations of climate classification

First, climate is a multidimensional concept, and it is not an obvious decision as to which of the many observed weather variables should be selected as the basis of the classification. This choice must be made on a number of grounds, both practical and theoretical. For example, using too many different elements opens up the possibilities that the classification will have too many categories to be readily interpreted and that many of the categories will not correspond to real climates. Moreover, measurements of many of the elements of climate are not available for large areas of the world or have been collected for only a short time. The major exceptions are temperature and precipitation data, which are available almost universally and have been recorded for extended periods of time.

The choice of variables also is determined by the purpose of the classification (*e.g.*, to account for distribution of natural vegetation, to explain soil formation processes, or to classify climates in terms of human comfort). The variables relevant in the classification will be determined by this purpose, as will the threshold values of the variables chosen to differentiate climatic zones.

A second difficulty results from the generally gradual nature of changes in the climatic elements over the Earth's surface. Except in unusual situations due to mountain ranges or coastlines, temperature, precipitation, and other climatic variables tend to change only slowly over distance. As a result, climate types tend to change imperceptibly as one moves from one locale to an adjacent one. Choosing a set of criteria to distinguish one climatic type from another is thus equivalent to drawing a line on a map to distinguish the climatic region possessing one type from that having the other. While this is in no way different from many other classification decisions that one makes routinely in daily life, it must always be remembered that boundaries between adjacent climatic regions are placed somewhat arbitrarily through regions of continuous, gradual change and that the areas defined within these boundaries are far from homogeneous in terms of their climatic characteristics.

Most classification schemes are intended for global- or continental-scale application and define regions that are major subdivisions of continents hundreds to thousands of kilometres across. These may be termed macroclimates. Not only will there be slow changes (from wet to dry, hot to cold, etc.) across such a region as a result of the geographic gradients of climatic elements over the continent of which the region is a part, but there will exist mesoclimates within these regions associated with climatic processes occurring at a scale of tens to hundreds of kilometres that are created by elevation differences, slope aspect, bodies of water, differences in vegetation cover, urban areas, and the like. Mesoclimates, in turn, may be resolved into numerous microclimates, which occur at scales of less than 0.1 kilometre, as in the climatic differences between forests, crops, and bare soil, at various depths in a plant canopy, at different depths in the soil, on different sides of a building, and so on.

Mesoclimates and microclimates

These limitations notwithstanding, climate classification plays a key role as a means of generalizing the geographic distribution and interactions among climatic elements, of identifying mixes of climatic influences important to various climatically dependent phenomena, of stimulating the search to identify the controlling processes of climate, and, as an educational tool, to show some of the ways in

which distant areas of the Earth are both different from and similar to one's own home region.

Approaches to climatic classification

The earliest known climatic classifications were those of classical Greek times. Such schemes generally divided the Earth into latitudinal zones based on the significant parallels of 0°, 23.5°, and 66.5° of latitude and on the length of day. Modern climate classification has its origins in the mid-19th century, with the first published maps of temperature and precipitation over the Earth, which permitted the development of methods of climate grouping that used both variables simultaneously.

Principal types of classification schemes

Many different schemes of classifying climate have been devised (more than 100), but all of them may be broadly differentiated as either empiric or genetic methods. This distinction is based on the nature of the data used for classification. Empiric methods make use of observed climatic data, such as temperature, humidity, and precipitation, or simple quantities derived from them (*e.g.,* evaporation). In contrast, a genetic method classifies climate on the basis of its causal elements, the activity and characteristics of all factors (air masses, circulation systems, fronts, jet streams, solar radiation, topographic effects, and so forth) that give rise to the spatial and temporal patterns of climatic data. Hence, while empiric classifications are largely descriptive of climate, genetic methods are (or should be) explanatory. Unfortunately, genetic schemes, while scientifically more desirable, are inherently more difficult to implement because they do not use simple observations of the atmosphere. As a result, such schemes are both less common and less successful overall. Moreover, the regions defined by the two types of classification schemes do not necessarily correspond; in particular, it is not uncommon for similar climatic forms resulting from different climatic processes to be grouped together by many common empiric schemes.

Empiric methods may be subdivided further based on the manner in which the climatic data are used. Some approaches attempt to employ climatic data directly and to group patterns of their statistics on some "rational" basis, drawing guidance from the numbers themselves. More commonly, however, climates have been classified on the basis of the response of some phenomenon to climate. For example, climatic types have been differentiated on the basis of natural vegetation distributions, human comfort, soil formation, rock weathering, and myriad other factors whose intensity, nature, or distribution are felt to be controlled or influenced by climate. As such, criteria for differentiating different climatic groups are determined by the assumed behaviour of the phenomenon chosen to relate to climate rather than the statistical properties of the data themselves. The distinction between these two empiric approaches is not as clear as might at first be thought, however. While the thresholds chosen to differentiate groups might be determined by the characteristics of the climatic statistics themselves, the choice of variables on which to base the classification is made by its author. That choice is made on the basis of some perceived significance in the variables selected. This perception implies some subjective view of the nature of climate or its significance to some dependent phenomenon.

GENETIC CLASSIFICATIONS

Major types of genetic classification

Genetic classifications group climates by their causes. Among such methods, three types may be distinguished: (1) those based on the geographic determinants of climate, (2) those based on the surface energy budget, and (3) those derived from air-mass analysis.

In the first class are a number of schemes (largely the work of German climatologists) that categorize climates according to such factors as latitudinal control of temperature, continentality versus oceanicity, location with respect to pressure and wind belts, and effects of mountains. These classifications all share a common shortcoming: they are qualitative, so that climatic regions are designated in a subjective manner rather than as a result of the application of some rigorous differentiating formula.

An interesting example of a method based on the energy balance of the Earth's surface is the 1970 classification of Werner H. Terjung, an American geographer. His method utilizes data for more than 1,000 locations worldwide on the net radiation received at the surface, the available energy for evaporating water and for heating the air and subsurface. The annual patterns are classified according to the maximum energy input, the annual range in input, the shape of the annual curve, and the number of months with negative magnitudes. The combination of characteristics for a location is represented by a label consisting of several letters with defined meanings, and regions having similar net radiation climates are mapped.

Genetic systems employing air-mass concepts

Probably the most extensively used genetic systems, however, are those that employ air-mass concepts. Air masses are large bodies of air that in principle possess relatively homogeneous properties of temperature, humidity, etc., in the horizontal. Weather on individual days may be interpreted in terms of these features and their contrasts at fronts, which suggests that climate, as a synthesis of weather, can be treated likewise. While air masses are the proximate causes of climate rather than the ultimate controls (which are the factors that gave the air masses their characteristics), this approach can still be properly regarded as genetic.

Two American geographer-climatologists have been most influential in classifications based on air mass. In 1951 Arthur N. Strahler described a qualitative classification based on the combination of air masses present at a given location throughout the year. Some years later (1968 and 1970), John E. Oliver placed this type of classification on a firmer footing by providing a quantitative framework that designated particular air masses and air mass combinations as "dominant," "subdominant," or "seasonal" at particular locations. He also provided a means of identifying air masses from diagrams of mean monthly temperature and precipitation plotted on a "thermohyet diagram," a procedure that obviates the need for less common upper-air data to make the classification.

EMPIRIC CLASSIFICATIONS

Most empiric classifications are those that seek to group climates according to their effects on some climate-dependent phenomenon. While many such phenomena have been used in this way, natural vegetation stands out as one of prime importance. The view held by many botanist-climatologists is that natural vegetation functions as an integrator of the characteristics of climate in a region; the vegetation, in effect, is an instrument for measuring climate in the same way that a thermometer measures temperature. That this view is an oversimplified one is undoubtedly true. Nevertheless, it has been a prime motivation of many climatologists, and its preeminence is apparent in the fact that many textbooks and other sources refer to climates using the names of vegetation, as, for example, rain-forest, taiga, or tundra.

Natural vegetation in empiric classification

Wladimir Köppen, a German botanist-climatologist, developed the most popular (but not the first) of these vegetation-based classifications. His aim was to devise formulas that would define climatic boundaries in such a way as to correspond to those of the vegetation zones that were being mapped for the first time during his lifetime. Köppen published his first scheme in 1900 and a revised version in 1918. He continued to revise his system of classification until his death in 1940. Other climatologists have modified portions of Köppen's procedure on the basis of their experience in various parts of the world.

The Köppen classification system

Köppen's classification is based on a subdivision of terrestrial climates into five major types, which are represented by the capital letters A, B, C, D, and E. Each of these climate types except for B is defined by temperature criteria. Type B designates climates in which the controlling factor on vegetation is dryness (rather than coldness). Aridity is not a matter of precipitation alone but is defined by the relationship between the precipitation input to the soil in which the plants grow and the evaporative losses. Since evaporation is difficult to evaluate and is not a conventional measurement at meteorological stations, Köppen was forced to substitute a formula that identifies

aridity in terms of a temperature-precipitation index (*i.e.*, evaporation is assumed to be controlled by temperature). Dry climates are divided into arid (BW) and semiarid (BS) subtypes, and each may be differentiated further by adding a third code, h for warm and k for cold.

As noted above, temperature defines the other four major climate types. These are subdivided, with additional letters again used to designate the various subtypes. Type A climates (the warmest) are differentiated on the basis of the seasonality of precipitation: Af (no dry season), Am (short dry season), or Aw (winter dry season). Type E climates (the coldest) are conventionally separated into tundra (ET) and snow/ice climates (EF). The mid-latitude C and D climates are given a second letter, f (no dry season), w (winter dry), or s (summer dry), and a third symbol (a, b, c, or d [the last subclass exists only for D climates]), indicating the warmth of the summer or the coldness of the winter. Table 6 gives the specific criteria for the Köppen–Geiger–Pohl system of 1953.

The Köppen classification has been criticized on many grounds. It has been argued that extreme events, such as a periodic drought or an unusual cold spell, are just as significant in controlling vegetation distributions as the mean conditions upon which Köppen's scheme is based. It also has been pointed out that meteorological factors other than those used in the classification, such as sunshine and wind, are important to vegetation. Moreover, it has been contended that vegetation can respond only slowly to climate, so that the vegetation zones observable today are in part adjusted to past climates. Many critics have drawn attention to the rather poor correspondence between the Köppen zones and the observed vegetation distribution in many areas of the world. In spite of these and other limitations, the Köppen system remains the most popular climatic classification in use today.

Thornthwaite's classification

A major contribution to climate grouping was made by the American geographer-climatologist C. Warren Thornthwaite in 1931 and 1948. He first used a vegetation-based approach that made use of the derived concepts of temperature efficiency and precipitation effectiveness as a means of specifying climatic effects on vegetation. His second classification retained these concepts in the form of a moisture index and a thermal efficiency index but radically changed the classification criteria and rejected the idea of using vegetation as the climatic integrator, attempting instead to classify "rationally" on the basis of the numerical values of these indices. His 1948 scheme is encountered in many climatology texts, but it has not gained as large a following among a wider audience as the Köppen classification system, perhaps because of its complexity and the large number of climatic regions it defines.

While vegetation-based climate classifications could be regarded as having relevance to human activity through what they may indicate about agricultural potential and natural environment, they cannot give any sense of how human beings would feel within the various climate types. Terjung's 1966 scheme was an attempt to group climates on the basis of their effects on human comfort. The classification makes use of four physiologically relevant parameters: temperature, relative humidity, wind speed, and solar radiation. The first two are combined in a comfort index to express atmospheric conditions in terms perceived as extremely hot, hot, oppressive, warm, comfortable, cool, keen, cold, very cold, extremely cold, and ultra cold. Temperature, wind speed, and solar radiation are combined in a wind effect index expressing the net effect of wind chill and addition of heat to the human body by solar radiation. These indices are combined for different seasons in different ways to express how humans feel in various geographic areas on a yearly basis. Terjung visualized that his classification would find applicability in medical geography, climatological education, tourism, housing, clothing, and as a general analytical tool.

Terjung's comfort index

Many other specialized empirical classifications have been devised. For example, there are those that differentiate between types of desert and coastal climates, those that account for different rates of rock weathering or soil formation, and those based on the identification of similar agricultural climates.

Table 6: Criteria for Classifying Major Climatic Types According to the Köppen–Geiger–Pohl Scheme (1953)

letter symbol			criterion
1st	2nd	3rd	
A			temperature of coolest month 18° C or higher
	f		precipitation in driest month at least 60 mm
	m		precipitation in driest month less than 60 mm but equal to or greater than $100-(r/25)$*
	w		precipitation in driest month less than 60 mm and less than $100-(r/25)$
B†			70% or more of annual precipitation falls in the summer half of the year and r less than $20t+280$, or 70% or more of annual precipitation falls in the winter half of the year and r less than $20t$, or neither half of the year has 70% or more of annual precipitation and r less than $20t+140$‡
	W		r is less than one-half of the upper limit for classification as a B type (see above)
	S		r is less than the upper limit for classification as a B type but is more than one-half of that amount
		h	t equal to or greater than 18° C
		k	t less than 18° C
C			temperature of warmest month greater than or equal to 10° C, and temperature of coldest month less than 18° C but greater than −3° C
	s		precipitation in driest month of summer half of the year is less than 30 mm and less than one-third of the wettest month of the winter half
	w		precipitation in driest month of the winter half of the year less than one-tenth of the amount in the wettest month of the summer half
	f		precipitation more evenly distributed throughout year; criteria for neither s nor w satisfied
		a	temperature of warmest month 22° C or above
		b	temperature of each of four warmest months 10° C or above but warmest month less than 22° C
		c	temperature of one to three months 10° C or above but warmest month less than 22° C
D			temperature of warmest month greater than or equal to 10° C, and temperature of coldest month −3° C or lower
	s		same as for type C
	w		same as for type C
	f		same as for type C
		a	same as for type C
		b	same as for type C
		c	same as for type C
		d	temperature of coldest month less than −38° C (d designation then used instead of a, b, or c)
E			temperature of warmest month less than 10° C
	T		temperature of warmest month greater than 0° C but less than 10° C
	F		temperature of warmest month 0° C or below

*In the formulas above, r is average annual precipitation total (mm) and t is average annual temperature (° C). All other temperatures are monthly means (° C), and all other precipation amounts are mean monthly totals (mm). †Any climate that satisfies the criteria for designation as a B type is classified as such, irrespective of its other characteristics. ‡The summer half of the year is defined as the months April–September for the Northern Hemisphere and October–March for the Southern Hemisphere.

World distribution of major climatic types

The following discussion of the climates of the world is based on groupings of Köppen's climatic types. It should be read in conjunction with Table 6 (for the specific criteria defining each type), Figure 56 (for the geographic extent of each type), and Figure 57 (which provides sample annual temperature and precipitation data for many of the climates discussed).

TYPE A CLIMATES

Köppen's A climates are found in a nearly unbroken belt around the Earth at low latitudes, mostly within 15° N and S. Their location within a region in which available net solar radiation is large and relatively constant from month to month ensures both high temperatures (generally in excess of 18° C) and a virtual absence of thermal seasons. Typically, the temperature difference between day and night is greater than that between the warmest and the coolest month, the opposite of the situation in mid-latitudes. The terms winter and summer have little meaning, but in many locations annual rhythm is provided by the occurrence of wet and dry seasons. Type A climates are controlled mainly by the seasonal fluctuations of the trade winds, the intertropical convergence zone (ITCZ), and the Asian monsoon (see above *Wind*).

Wet equatorial climate (Af). Within about 12° latitude of the Equator lies a region of consistently high temperatures (around 30° C), with plentiful precipitation (150–1,000 centimetres), heavy cloud cover, and high humidity, with very little annual temperature variation. Such regions lie within the influence of the ITCZ in all months; the converging, ascending air spawns convectional thunderstorm activity with much of the rainfall occurring in late afternoon or early evening when the atmosphere is most susceptible to thunderstorms. While precipitation is profuse in all months, variations do occur in response to the precise location of the ITCZ, drier months resulting when the circulation brings the region to its periphery. Other zones of Af climate are found beyond the usual margins of ITCZ activity, in coastal Madagascar, southeast coastal Brazil, and much of Central America and western Colombia, where trade winds blow onshore all year to encounter coastlines backed by mountain barriers that stimulate the formation of precipitation as warm, moist tropical air is forced to ascend and cool. Such regions also may receive precipitation from tropical disturbances, including hurricanes.

Effect of the ITCZ

Tropical monsoon and trade-wind littoral climates (Am). These climates resemble the Af in most characteristics, with small annual temperature ranges, high temperatures, and plentiful precipitation (often more than Af climates in annual total). They differ from the latter, however, in that they exhibit a short dry season, usually in the low-sun ("winter") season. The highest temperatures generally occur at the end of this clear spell. Two distinct processes can give rise to Am climate types. The largest areas, mostly in southern and southeastern Asia, result from the Asian monsoon circulation that brings convective and orographic precipitation in the summer when warm, moist maritime tropical air moves over land to converge into the low-pressure zone north of the Himalayas. In winter, by contrast, cool, dry air diverges out of the Siberian anticyclone to the north, bringing a cooler, drier, and clearer period of variable length. In the Americas and in Africa, continents that are not large enough to generate a true monsoon circulation, Am climates are of the trade-wind littoral variety. These areas receive precipitation on narrow coastal strips through orographic effects as the moist air of the trade winds ascends mountain chains. Seasonal migrations and changes in the intensity of these winds give rise to short, moderately dry seasons. Summer precipitation may be enhanced by tropical disturbances traveling in the trade winds.

Tropical wet-dry climate (Aw). This climate has distinct wet and dry seasons, with most of the precipitation occurring in "summer." Total amounts of rainfall are less than in the previous two climate types (50–175 centimetres), most of which occur in convectional thunderstorms. The dry season is longer than in the Am climates and becomes progressively longer as one moves poleward through the region. Temperatures are high throughout the year but show a greater range than Af and Am climates (19°–20° C in winter and 24°–27° C in summer). Throughout most of the region, the cause of the seasonal cycle is the shift in the tropical circulation throughout the year. During the high-sun season, the ITCZ moves poleward and brings convergent and ascending air to these locations, which stimulates convective rainfall. During the low-sun season, the convergence zone moves off to the winter hemisphere and is replaced by the periphery or core of the subtropical anticyclone, with its subsiding, stable air resulting in a period of dry, clear weather, the intensity and length of which depend on latitude.

TYPE B CLIMATES

Arid and semiarid climates

Arid and semiarid climates cover about a quarter of the Earth's land surface, mostly between 50° N and 50° S, but they are mainly found in the 15°–30° latitude belt in both hemispheres. They exhibit low precipitation, great variability in precipitation from year to year, low relative humidity, high evaporation rates (when water is available), clear skies, intense solar radiation, and high wind speeds.

Tropical and subtropical desert climate (BWh, part of BWk). Most of the tropical, true desert (BW) climates of the Earth occur between 15° and 30° latitude, at the poleward end of the Hadley cell circulation (see above). These regions are dominated in all months by the subtropical anticyclone, with its descending air, elevated inversions, and clear skies. This is an atmospheric environment that

inhibits precipitation. The most extreme arid areas also are far removed from sources of moisture-bearing winds in the interiors of continents and are best developed on the western sides of continents, where the subtropical anticyclone shows its most intense development. An exception to the general tendency for aridity to be associated with subsidence is in the so-called Horn of Africa region, where the dryness of Somalia is caused more by the orientation of the landmass in relation to the atmospheric circulation. Both the high- and low-sun monsoonal winds blow parallel to the coast, so that moisture-laden maritime air can penetrate over land only infrequently. In most low-latitude deserts, cloud cover is uncommon (fewer than 30 days per year have clouds in some areas). Precipitation amounts are mostly in the range 0–25 centimetres, although the unreliability of precipitation is more significant than the small totals. Average figures have little meaning; a location with a 10-year mean of five centimetres, for example, might have received 50 centimetres in one year as a result of an unusual intrusion of moist air, followed by nine years with no measurable precipitation.

Temperatures are high, with monthly means in the range 21°–32° C. Daily temperature variations are extreme. Ranges of 35° C are not unknown when daytime maxima in excess of 40° C are followed by a rapid nocturnal temperature drop brought about by the limited capacity of the dry, cloudless desert air to emit infrared radiation to the ground to offset radiation loss from the surface at night. The highest air temperatures recorded on Earth have been in the BWh regions; for example, Death Valley in the western United States has reached 57° C, while al-ʿAzīzīyah in Libya has had a recorded high of 58° C. Actual surface temperatures may reach 82° C on dry sand under intense sunshine.

An interesting variant of tropical and subtropical deserts are the so-called West Coast Desert areas found on the western coastal margins of the regions discussed above (*e.g.*, in the Sonoran Desert of North America, the Peru and Atacama deserts of South America, and the Sahara [Moroccan part] and Namib deserts of Africa). These areas are much cooler than their latitude would suggest (monthly mean temperatures of only 15°–21° C), and parts are classified as BWk in Köppen's scheme. The cooling results from air flow off adjacent coastal waters where upwelling of the ocean gives rise to cold currents. Deserts of this sort are subject to frequent fog and low-level clouds; yet they are extremely arid. Some parts of the Atacama Desert, for example, have recorded no precipitation for 20 years.

Tropical and subtropical steppe climate (BSh). The low-latitude semiarid (or steppe) climate occurs primarily on the periphery of the true deserts treated above. It is transitional to the Aw climate on the equatorward side (showing a summer rainfall maximum associated with the ITCZ and a small annual temperature range) and to the Mediterranean climate on its poleward margin (with a cooler, wetter winter resulting from the higher latitude and mid-latitude frontal cyclone activity). Annual precipitation totals are greater than in BW climates (38–63 centimetres). Yearly variations in amount are not as extreme as in the true deserts but are nevertheless large.

Mid-latitude steppe and desert climate (BSk, part of BWk). Although these climates are contiguous with the tropical dry climates of North and South America and of central Asia, they have different origins. Cool true deserts extend to 50° latitude and cool steppes reach nearly 60° N in the Canadian Prairies, well beyond the limits of the subtropical anticyclone. These climates owe their origins to locations deep within continental interiors, far from the windward coasts and sources of moist, maritime air. Remoteness from sources of water vapour is enhanced in some regions (*e.g.*, the Great Plains of the United States) by mountain barriers upwind. Temperature conditions are extremely variable, with annual means decreasing and annual ranges increasing poleward. In the higher latitudes, winters are severely cold, with meager precipitation (much of it in the form of snow) associated with polar and arctic air in frontal cyclones. Summer precipitation is more often convective, arriving in the form of scattered thunderstorm activity brought about by irregular incursions of moist air. Both BWk and BSk climates in the mid-latitudes owe their origins to these mechanisms, but the steppe type tends to be located peripheral to the true desert, either adjacent to the moister C and D climates or at the poleward extent of the range, where reduced evaporation under cooler conditions makes more of the scarce precipitation available as soil moisture for plant growth.

TYPE C AND D CLIMATES

Through a major portion of the middle and high latitudes (mostly from 25° to 70° N and S) lies a group of climates classified within the Köppen scheme as C and D types. Most of these regions lie beneath the upper-level, mid-latitude westerlies throughout the year, and it is in the seasonal variations in location and intensity of these winds and their associated features that the explanation of their climatic character must be sought. During summer, the polar-front and its jet stream move poleward, and air masses of tropical origin are able to extend to high latitudes. During winter, as the circulation moves equatorward, tropical air retreats and cold polar outbreaks influence weather, even within the subtropical zone. The relative frequency of these air masses of different origins varies gradually from low to high latitude and is largely responsible for the observed temperature change across the belt (which is most marked in winter). The air masses interact in the frontal systems commonly found embedded within the traveling cyclones that lie beneath the polar-front jet stream. Ascent induced by convergence into these low-pressure cells and by uplift at fronts induces precipitation, the main location of which shifts with the seasonal circulation cycle. Other important sources of precipitation are convection, mainly in tropical air, and forced uplift at mountain barriers. Monsoon effects modify this general pattern in eastern Asia, while the subtropical anticyclone plays a role in the explanation of climate on the western sides of the continents in the subtropics.

Principal sources of precipitation

Humid subtropical climate (Cfa, Cwa). These climates are found on the eastern sides of the continents between 20° and 35° N and S latitude. Most show a relatively uniform distribution of precipitation throughout the year (the Cfa types), with totals in the range 75–150 centimetres. In summer these regions are largely under the influence of moist, maritime airflow from the western side of the subtropical anticyclonic cells over low-latitude ocean waters. Temperatures are high; the warmest months generally average about 27° C, with mean daily maxima from 30 ° to 38° C and warm, oppressive nights. Summers are usually somewhat wetter than winters, with much of the rainfall coming from convectional thunderstorm activity; tropical cyclones also enhance warm-season rainfall in some regions. The coldest month is usually quite mild (5°–12° C), although frosts are not uncommon, and winter precipitation is derived primarily from frontal cyclones along the polar front. In North America the spring and early summer seasons, when the front begins its northward return, are notorious for the outbreak of tornadoes associated with frontal thunderstorms along the zone of interaction between tropical and polar air. In eastern and southern Asia the monsoon influence results in a modified humid subtropical climate (Cwa) that has a clearly defined dry winter when air diverges from the Siberian anticyclone and the polar front and cyclone paths are deflected around the region. These areas generally lie on the poleward side of Am and Aw climates and exhibit a somewhat larger annual temperature range than Cfa types. Winters are sunny and rather cool. Annual precipitation totals average about 100 centimetres but vary from 75 centimetres to 200 centimetres.

High incidence of tornadoes

Mediterranean climate (Csa, Csb). Between about 30° and 45° latitude on the western sides of the continents is found a series of climates that show the unusual combination of hot, dry summers and cool, wet winters. Poleward extension and expansion of the subtropical anticyclonic cells over the oceans bring subsiding air to the region in summer, with clear skies and high temperatures. When the anticyclone moves equatorward in winter, it is replaced by traveling, frontal cyclones with their attendant precipitation. Annual temperature ranges are generally smaller than those found in the Cfa climates, since locations on the western sides of continents are not well positioned to receive the coldest polar air, which develops over land rather than over the ocean. Mediterranean climates also tend to be drier than humid subtropical ones, with precipitation totals ranging from 35 to 90 centimetres; the lowest amounts occur in interior regions adjacent to the semiarid steppe climates. Some coastal locations (*e.g.*, southern California in the western United States) exhibit relatively cool summer conditions and frequent fogs where cold offshore currents prevail. Only in Europe where the latitude for this climate type fortuitously corresponds to an ocean basin (that of the Mediterranean, from which this climate derives its name) does the Cs type extend eastward away from the coast for any significant distance.

Marine west coast climate (Cfb, Cfc). Poleward of the Mediterranean climate region on the western sides of the continents, between 35° and 60° N and S latitude are regions that exhibit ample precipitation in all months. Unlike their equatorward neighbours, these areas are located beyond the farthest poleward extent of the subtropical anticyclone, and they experience the mid-latitude westerlies and traveling frontal cyclones all year. Precipitation totals vary somewhat throughout the year in response to the changing location and intensity of these storm systems, but annual accumulations generally range from 50 to 250 centimetres, with local totals exceeding 500 centimetres where onshore winds encounter mountain ranges. Not only is precipitation plentiful but it is also reliable and frequent. Many areas have rainfall more than 150 days per year, although the precipitation is often of low intensity. Fog is common in autumn and winter, but thunderstorms, tornadoes, and hurricanes are infrequent. Strong gales with high winds, however, may be encountered in

Equable climates

winter. These are equable climates with few extremes of temperature. Annual ranges are rather small (10°–15° C), about half those encountered farther to the east in the continental interior at the same latitude. Mean annual temperatures are usually 7°–13° C in lowland areas, the winters are mild, and the summers are relatively moderate, rarely having monthly temperatures above 20° C.

In North and South America, Australia, and New Zealand, north–south mountain ranges backing the west coasts of the landmasses at these latitudes confine the marine west coast climate to relatively narrow coastal strips (but enhance precipitation). By contrast, in Europe the major mountain chains (the Alps and Pyrenees) run east–west, permitting Cfb and Cfc climates to extend inland some 2,000 kilometres into East Germany and Poland.

Humid continental climate (Dfa, Dfb, Dwa, Dwb). The D climates are primarily northern hemispheric phenomena, since landmasses are absent at the significant latitudes in the Southern Hemisphere. The humid continental subgroup occupies a region between 30° and 60° N in central and eastern North America and Asia in the major zone of conflict between polar and tropical air masses. These regions exhibit large seasonal temperature contrasts with hot summers and cold winters. Precipitation tends to be ample throughout the year in the Df section, being derived both from frontal cyclones and, in summer months, from convectional showers when maritime tropical air pushes northward behind the retreating polar front. Many areas show a distinct summer precipitation maximum because of this convective activity, although more uniform patterns are not uncommon. Severe thunderstorms and tornadoes are an early summer occurrence when the polar front is in the southern margin of the Dfa region. Winter precipitation often occurs in the form of snow, and a continuous snow cover is established for from one to four months in many parts of the region, especially in the north. This snow often arrives in conjunction with high winds from an intense frontal cyclone, giving rise to a blizzard.

Large contrasts in seasonal temperatures

Winters tend to be cold but are subject to occasional frigid or mild spells brought about by periodic incursions of arctic or tropical air. Indeed the changeable nature of weather in all seasons is a characteristic feature of the climate, especially in such areas as the eastern United States and Canada where there are few topographic barriers to limit the exchange of air masses between high and low latitudes. Mean temperatures are typically below freezing from one to several months, and the frost-free season varies from fewer than 150 to 200 days per year. Annual precipitation totals range from 50 to 125 centimetres, with higher amounts in the south of the region and in the uplands.

In eastern Asia (Manchuria and Korea), a monsoonal variant of the humid continental climate (Dwa, Dwb) occurs. This climate type has a pronounced summer precipitation maximum and a cold, dry winter dominated by continental polar air diverging out of the nearby Siberian anticyclone.

Continental subarctic climate (Dfc, Dfd, Dwc, Dwd). North of the humid continental climate, from about 50° to 70° N, in a broad swath extending from Alaska to Newfoundland in North America and from northern Scandinavia to Siberia in Eurasia, lie the continental subarctic climates. These are regions dominated by the winter season, a long, bitterly cold period with short, clear days, relatively little precipitation (mostly in the form of snow), and low humidity. In Asia the Siberian anticyclone, the source of continental polar air, dominates the interior, and mean temperatures 40°–50° C below freezing are not unusual. The North American representative of this climate is not as severe but is still profoundly cold. Mean monthly temperatures are below freezing for six to eight months, with an average frost-free period of only 50–90 days per year, and snow remains on the ground for many months. Summers are short and mild, with long days and a prevalence of frontal precipitation associated with maritime tropical air within traveling cyclones. Mean temperatures in summer only rarely exceed 16° C, except in interior regions where values near 25° C are possible. As a result of these temperature extremes, annual temperature ranges are larger in continental subarctic climates than in any other climate type on Earth, up to 30° C through much of the area and more than 60° C in central Siberia, although coastal areas are more moderate. Annual precipitation totals are mostly less than 50 centimetres, with a concentration in the summer. Higher totals, however, occur in marine areas near warm ocean currents. Such areas also are generally somewhat more equable and may be designated marine subarctic climates (see Figure 57). Areas with a distinct dry season in winter, which results in the Köppen climate types Dwc and Dwd, occur in eastern Siberia, both in the region where the wintertime anticyclone is established and in the peripheral areas subject to dry, divergent airflow from it.

Dominance of the Siberian anticyclone

TYPE E CLIMATES

Köppen's type E climates are controlled by the polar and arctic air masses of high latitudes (60° N and S and higher). These climates are characterized by low temperatures and precipitation and by a surprisingly great diversity of subtypes.

Low precipitation and low temperatures

Tundra climate (ET). Tundra climates occur between 60° and 75° of latitude, mostly along the Arctic coast of North America and Eurasia and on the coastal margins of Greenland. Mean annual temperatures are below freezing and annual ranges are large (but not as large as in the adjacent continental subarctic climate). Summers are generally mild, with daily maxima from 15° to 18° C, although the mean temperature of the warmest month must be less than 10° C. Days are long (a result of the high latitude), but they are often cloudy. The snow cover of winter melts in the warmer season (though in places with mean annual temperatures of −9° C or less the ground at depth remains permanently frozen as permafrost); however, frosts and snow are possible in any month. Winters are long and cold (temperatures may be below 0° C for six to 10 months), especially in the region north of the Arctic Circle where, for at least one day in the year, the Sun does not rise. Winter precipitation generally consists of dry snow, with seasonal totals less than in the summer when cyclonic storms that develop along the boundary between the open sea and sea ice yield more rainfall. Typical annual totals are less than 35 centimetres, but a range from 25 to 100 centimetres is possible, with higher totals in upland areas and downwind of coasts. The latter regions also exhibit warmer winters, even in areas where the sea freezes; some climatologists regard them as a more equable polar marine subtype.

Snow and ice climate (EF). This climate (designated as Arctic in Figure 57) occurs poleward of 65° N and S latitude over the ice caps of Greenland and Antarctica and over the permanently frozen portion of the Arctic Ocean, the source regions for arctic air masses. Temperatures are below freezing throughout the year, and annual temperature ranges are large, but again not as large as in the continental subarctic climates. Winters are frigid, with mean monthly temperatures from −20° C to −65° C; the lowest temperatures occur at the end of the long polar night. The EF climate holds the distinction for the lowest recorded temperatures at the Earth's surface: the Vostok II research station in Antarctica holds the record for the lowest extreme temperature (−89° C), while the Plateau Station has the lowest annual mean (−56° C). Daily temperature variations are very small, because at such high latitudes the Sun's elevation varies little over the daylight period. Precipitation is meager in the cold, stable air (in most cases, five to 50 centimetres), with the largest amounts occurring on the coastal margins. Most of this precipitation results from the periodic penetration of a cyclone into the region, which brings snow and ice pellets and, with strong winds, blizzards. High winds also occur in the outer portions of the Greenland and Antarctic EF climates, where cold, dense air drains off the higher, central sections of the ice caps as katabatic winds (see above *Local wind systems*).

HIGHLAND CLIMATES

The major highland regions of the world (the Cascades, Sierra Nevada, and Rockies of North America, the Andes

of South America, the Himalayas and adjacent ranges and the Tibetan Highlands [or Plateau] of Asia, the eastern highlands of Africa, and the central portions of Borneo and New Guinea) cannot be classified realistically at this scale of consideration, since the effects of altitude and relief give rise to myriad mesoclimates and microclimates. This diversity over short horizontal distances is unmappable at the continental scale. Very little of a universal nature can be written about such mountain areas except to note that, as a rough approximation, they tend to resemble cooler, wetter versions of the climates of nearby lowlands in terms of their annual temperature ranges and seasonality of precipitation. Otherwise, only the most general characteristics may be noted.

Multitude of mesoclimates and microclimates

With increasing height, temperature, pressure, atmospheric humidity, and dust content decrease. The latter effect results in high atmospheric transparency and enhanced receipt of solar radiation (especially of ultraviolet wavelength) at elevation. Altitude also tends to increase precipitation, at least for the first 4,000 metres. The orientation of mountain slopes has a major impact on solar radiation receipt and temperature and also governs exposure to wind. Mountains can have other effects on the wind climate; valleys can increase wind speeds by "funneling" regional flows and may generate mesoscale mountain- and valley-wind circulations as well. Cold air also may drain from higher elevations to create "frost pockets" in low-lying valleys. Furthermore, mountains can act as barriers to the movement of air masses, can cause differences in precipitation amounts between windward and leeward slopes, and, if high enough, can collect permanent snow and ice on their peaks and ridges; the snow line varies in elevation from sea level in the subarctic to about 5,500 metres at 15°–25° latitude. (A.J.A.)

CLIMATE AND LIFE

Coevolution of climate and life

It has been well established that life and climate interact and that they have mutually altered each other over geologic history. In a sense, they have undergone coevolution, a term coined by the American biologists Paul R. Ehrlich and Peter H. Raven to describe the process whereby two or more species depend on the interactions between them. It might be said that the coevolution of life and climate during the past 4,000,000,000 years of Earth history is an expression for the incredibly complex mixture of forces causing climatic change.

THE DEVELOPING ATMOSPHERE

According to a widely held theory, the release of gases from the interior of the Earth during volcanic eruptions, along with other primitive processes, produced the planet's early atmosphere. Such processes determined the Earth's albedo (reflectivity to incoming solar radiation) and its heat-trapping "greenhouse" properties (see below *Causes of climatic change: The greenhouse effect*). Eventually carbon, hydrogen, oxygen, and nitrogen—the basic chemical constituents of life—were synthesized into primitive organic molecules from which early life forms subsequently evolved. This probably occurred during the first 500,000,000 years of Earth history. Anaerobic bacteria (those capable of living in the absence of oxygen) thrived in this early atmosphere, which consisted primarily of water vapour and carbon dioxide, with trace amounts of ammonia, methane, and various other gases. These organisms survived during this period because they found their ecological niche—*i.e.*, an environment having suitable chemical and physical conditions.

The evolution of atmospheric oxygen. Over an extended period of time, life contributes to the evolution of the natural environment, just as changing environmental conditions influence the development of organisms and their ability to survive. This interaction is exemplified by the evolution of atmospheric oxygen. The large volume of oxygen found today in the atmosphere accumulated over billions of years largely as a result of two processes. One of these consists of mechanisms for removing oxygen from the air and ocean and converting it to an oxide sediment, such as iron oxide. The other process is photosynthesis, a primary producer of oxygen. It seems likely that, once the continental crust was well oxidized (a comparatively efficient process), the absorption and conversion of free oxygen was controlled by oceanic mechanisms, which became less efficient. Thus, the production of oxygen by photosynthesizing organisms on an ever-expanding scale eventually outstripped the oxygen-removing capabilities of the environment. Ironically, the increasing supply of atmospheric oxygen was a disaster for many of the primitive anaerobic bacteria that produced it. Yet, the oxygen-rich atmosphere opened the door to the development of higher life forms.

Importance of photosynthesis

The Gaia hypothesis. The close interrelation between life and its environment, and its philosophical significance, was noted by the British chemist James E. Lovelock and the American biologist Lynn Margulis. They called this idea of complementary evolution of life and environment the Gaia hypothesis after Gaia, the ancient Greek goddess of the Earth. As Lovelock put it, this is "a new insight into the interactions between the living and the inorganic parts of the planet. From this has arisen the hypothesis, the model, in which the Earth's living matter, air, oceans, and land surface form a complex system which can be seen as a single organism and which has the capacity to keep our planet a fit place for life."

The Gaia hypothesis is highly controversial because it intimates that individual species (*e.g.*, ancient anaerobic bacteria) might sacrifice themselves for the benefit of all living things. Furthermore, the hypothesis has yet to be formulated quantitatively and in a scientifically testable manner. However, regardless of the eventual validity of the idea that life controls its environment for its own benefit, the recognition that the Earth's physical, chemical, and biological components interact and mutually alter their collective destiny, by accident or design, is a profound insight.

CAUSES OF CLIMATIC CHANGE

The fact that climate influences terrestrial life is readily apparent. At the same time, it is all too clear that humans and other constituents of the biosphere affect climate significantly. Although many details about the interdependence of climate and the biosphere remain unknown, it has been firmly determined that there are relatively fixed supplies of certain elements essential to life (*i.e.*, nutrients) that circulate in the environment. These materials are transported (by wind or water, for example) and transformed chemically into forms that can be used by living things.

Interdependence of climate and the biosphere

Nutrients move in biogeochemical cycles. Climate, through atmospheric circulation, influences life by its effect on the flow of nutrients through these cycles. Many of these materials help to determine the composition of the atmosphere, which in turn affects climate. Water vapour is one such material. When it forms clouds, the Earth's albedo changes and more of the Sun's rays are reflected back into space. There is less heating, and so the climate is altered. (Water vapour and clouds also are important elements in the greenhouse warming effect; see below.)

Water is one of the most important nutrients for sustaining life, and its movement is termed the hydrologic cycle. What kinds of vegetation will grow in a given location is largely determined by the availability of water. Water is transferred to the air by means of evaporation and transpiration. Evaporation is the process whereby liquid water both from bodies of water (*e.g.*, rivers and lakes) and from the soil is transformed to water vapour. Transpiration involves the discharge of water vapour to the atmosphere from the surfaces of plants, particularly from their leaves. The total transfer of moisture to the

air via both these processes is termed evapotranspiration. On a global average, evapotranspiration on land is about six times less than evaporation of water from the ocean. Evapotranspiration, however, is often the principal local source of water vapour at the centres of continents.

Precipitation in the hydrologic cycle interacts with the so-called sedimentary cycle. Water helps to transport materials from the land to the sea, where they are incorporated into sediments. In the short term, this cycle consists of the processes of erosion, nutrient transport, and sediment formation. In the geologic, long-term sense, the sedimentary cycle utilizes mechanisms other than water flow. The processes involved are sedimentation, uplift, seafloor spreading, and continental drift.

The hydrologic and sedimentary cycles work together in the distribution of hydrogen, carbon, oxygen, nitrogen, phosphorus, and sulfur. These elements are the macronutrients, elements that account for 95 percent of the composition of all living organisms; they are necessary for sustaining life. The natural supply of these nutrients is fairly constant, with ample amounts existing within the Earth's crust. They are not always accessible, however, and must be recycled for life to continue.

The carbon cycle. The carbon cycle is the biogeochemical cycle that is probably of greatest interest to climatologists. Carbon exists in trace amounts in the atmosphere as carbon dioxide CO_2. It also exists in this and other forms in greater amounts in soil and bodies of water. Plants build their tissues with carbohydrates that are synthesized from CO_2 and water through photosynthesis, which utilizes solar energy. In spring and summer this process becomes more active because increasing sunlight and warmer temperatures help plants take CO_2 out of the air at a more rapid rate. In the Northern Hemisphere the concentration of CO_2 in the air decreases by a few percent from spring to fall (tens of billions of tons of CO_2 are involved). In the Southern Hemisphere the uptake of CO_2 is only about a third as much because there is less landmass and so fewer plants. In fall and winter the other part of the carbon cycle predominates as photosynthesis decreases and plants die and decay, introducing more CO_2 into the atmosphere than is removed by photosynthesis. Furthermore, the carbon cycle is influenced by exchanges of CO_2 between the atmosphere and the ocean. These exchanges are controlled by complex chemical processes in the ocean. In addition, other nutrients (*e.g.*, water and nitrogen) interact with carbon and life forms in an interlocking set of biogeochemical cycles. The very large carbon reservoirs in sedimentary rocks also are part of this biogeochemical cycling on a geologic time scale.

Absorption of infrared radiation by carbon dioxide

Although CO_2 constitutes only about 0.03 percent of the air, it affects the atmospheric heat balance because it absorbs infrared radiation. As a result, some of Earth's heat that ordinarily escapes as infrared rays into space is trapped by the atmosphere.

The greenhouse effect. This trapping of heat in the lower levels of the atmosphere is the so-called greenhouse effect. Next to water vapour, carbon dioxide is the most important gas in this process. There are other trace gases that, in concentration in the atmosphere, can create a strong greenhouse effect. Notable among these is methane (CH_4), which is produced by insects, humans, and other animals, and nitrous oxide (N_2O), which may be increasing due to the rapid growth in the use of nitrogen fertilizers. In satisfying its energy and agricultural needs, humankind has probably increased the amount of CO_2 in the atmosphere by 20 to 30 percent since the Industrial Revolution. Most projections point to roughly another 10 percent increase by the year 2000 and possibly as much as a 100 percent increase over preindustrial levels by the mid-21st century.

Using these estimates, global mean surface temperature could rise by approximately 1° C by the turn of the century and up to 5° C by the end of the 21st century. The latter figure approaches the magnitude of the average global temperature changes from glacial to interglacial periods. The implications of this warming are discussed below.

At this juncture, it is important to recall that climate largely determines what can grow where and the rate at which nutrients cycle through life and the environment. Completing the coevolutionary link between climate and life is the important fact that life affects the Earth's albedo and the composition of its atmosphere. Both of these regulate the energy balance of the planet, which in turn determines climate.

Reduction in rain-forest cover. Tropical rain forests play an important role in the exchange of gases between the biosphere and atmosphere. Significant amounts of nitrous oxide, carbon monoxide, and methane, for example, are released into the atmosphere from these forests. This metabolism is being changed by human activity. More than half of the carbon monoxide derived from tropical forests comes from their clearing and burning, which is reducing the size of such forests around the world.

Effects of deforestation

Another consequence of this deforestation must be examined. In the upper Amazon basin of South America, the rain forest recycles rains brought primarily by easterly trade winds. Surface transpiration and evaporation supply about half the rainfall for the entire region. In basins of dense forest cover far from the ocean, these local processes can account for most of the local rainfall. Should the Amazon Rain Forest, which accounts for 30 percent of the land area in the equatorial belt, disappear, drought would likely follow, and it might well affect the global energy balance. All around this equatorial belt, including Africa and the South Pacific islands, "forest farmers" are clearing portions of the rain forests each year. In some areas, it is being done to provide grazing land for more cattle with which to feed, at least in part, the nations of the Northern Hemisphere. In others, the deforestation is a survival response; that is to say, increasing population and uneven distribution of food supplies force the populace to expand their fields. Unfortunately, the soils in many parts of these cleared lands are not suitable for sustained agricultural use.

Impact of climate on human life

GENERAL OBSERVATIONS

Significance of short-term climatic variability

The interest in long-term atmospheric changes induced by human activities (anthropogenic changes) sometimes overshadows the fact that the natural short-term variability of climate also must be considered in assessing the influence of climate on society. Average, or mean, conditions are not a sufficient representation of the role climate plays in environmental and human affairs. Biologic systems are strongly affected by extremes in weather and climate. Accordingly, the character of climatic variability has an important effect on both natural and human communities and on the health of those communities.

A few obvious examples of the negative impact that natural climatic variability has had in the United States include the following. During the 1930s, crop and soil damage was the worst ever sustained in the Dust Bowl region of the central United States, and a forced emigration from the Great Plains reinforced the economic problems brought on by the Great Depression. In the winter of 1977, drought in the west and extreme cold in the east created economic disruptions estimated at billions of dollars. In the hot summer of 1980, the elderly, poor, and infirm in the south central states suffered abnormally high rates of mortality and morbidity. In addition, yields of such summer crops as corn and soybeans were greatly reduced. No thorough analysis of the distribution of losses and benefits resulting from climatic fluctuations of this sort has been made, but estimates put the net loss in the range of billions of dollars.

Experience with natural climatic fluctuations should be drawn upon both to develop policy measures with which to minimize society's vulnerability to anthropogenic climatic changes and to take advantage of new climatic resources. Atmospheric impact assessments for dealing with long-term problems usually involve an extrapolation of experience with the shorter-term effects of natural variability. Such experience, however, suggests that population size and the distribution and availability of resources mediate how natural climatic variability already affects society regardless of the existence of long-term climatic trends.

Thus, it is necessary to project how both climatic and societal factors will evolve and interact.

Day-to-day variability is an important atmospheric factor because society and the living environment respond nonlinearly to such variations. For example, the freezing point is a threshold below which small changes may have major effects on vegetation. Similarly, above certain temperatures, plant, animal, and human vitality can be seriously threatened. Since present-day climatic variability could well be superimposed on long-term climatic trends, one of the most significant effects of a seemingly small shift in the "mean" climate could be a large change in the frequency of harmful extreme situations.

WEATHER AND TECHNOLOGY

Climate-induced problems

In the latter part of the 1800s during the homesteading of the Great Plains, farmers were for the most part successful because the weather was generally favourable. Severe drought conditions in the 1890s, however, shattered the illusion that life on the plains was necessarily good and drove out many settlers. This pattern of boom-and-bust farming recurred several times: good weather and high-production years were followed by periods of drought, economic ruin, and serious soil erosion. The worst drought and resultant soil degradation occurred during the 1930s in the area of the Dust Bowl. Average wheat and corn yields fell by as much as 75 percent. Worse, millions of tons of valuable topsoil were lost.

As a result of this climate-induced disaster, the federal government established the U.S. Soil Conservation Service to help farmers protect the soil. Decades later new crop strains better adapted to regional climates were developed, and irrigation and chemical fertilizers were made available to take advantage of the new genetic strains and to promote production. These advances, together with the development of such technological aids as tractors, mechanical harvesters, irrigation pumps, and agrochemicals (*e.g.*, pesticides and herbicides), have increased the productivity (average yield of grain per harvested area) of the Great Plains by 200 to 300 percent since the 1930s. Total production (productivity multiplied by total harvested area) also has risen. In addition, the amount of year-to-year variability in yield, relative to the average yield, for most grains has decreased over time. Yet, while the relative variability (year-to-year variability as a percentage of long-term average yield) has generally declined for crops in recent years, the absolute variability (year-to-year variability in yield by itself) has increased on the whole in spite of all the technological advances.

The impact of agrotechnology

This has led to an ongoing debate about the relative role of climate versus the role of technological advances in influencing both average-yield and yield-variability trends during the 1960s and '70s. While agrotechnology appears to have been the prime factor behind the general increase in annual grain yield, there is some doubt as to its actual contribution to the favourable decrease of variability in relative yield. Some investigators, most notably the American geographer Richard Warrick, have argued that this decrease cannot be entirely attributed to modern farming practices. Only if the weather anomalies of the 1960s and '70s had been as bad as those from roughly 1930 to the late 1950s could agrotechnology be credited with the reduced impact of climatic stress on crop yields. Warrick and his associates compiled an index of the severity of summer droughts in the Great Plains in the period 1931–77 (Figure 58), which indicates quite clearly that since the late 1950s weather conditions have not been bad enough to test the hypothesis that technological advances have truly reduced the annual variations of grain yield. Given this situation, it is risky to assume that modern technology in the "breadbasket" of North America can stably maintain yearly productivity.

WORLD FOOD PRODUCTION AND CLIMATE

World food production outpaced population growth through the 1960s. Many began to believe that the technologies responsible for the so-called green revolution had ended the threat of Malthusian disaster. The worldwide events of 1972 and those of 1974 in the United States and Canada badly shook the conviction that technology had finally solved the problem of world hunger.

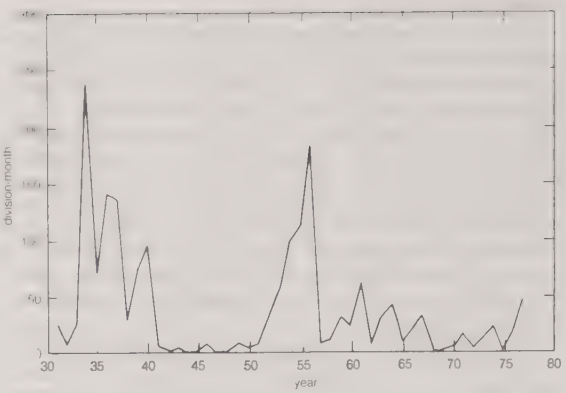

Figure 58: U.S. Great Plains drought area, 1931–77. Shown here is the number of divisions exhibiting severe or extreme drought (≦ −3.00) conditions, based on Palmer index values summed over five months, April through August. The more intense the drought, the higher the division-month number.

From R.A. Warrick, "Drought in the Great Plains: A Case Study of Research on Climate and Society in the U.S.A.," in J. Ausubel and A.K. Biswas (eds.), *Climatic Constraints and Human Activities* (1980). Pergamon Press Ltd. reprinted with permission

Adverse effects of global weather conditions. The year 1972 was not a good year for much of the world. There were serious climatic, economic, and human setbacks: severe droughts occurred in what was then the Soviet Union, India, Southeast Asia, Australia, Central and South America, and the Sahel region of Africa; Peru's protein-rich anchovy fishery was devastated as a result of an El Niño event (see below); and grain supplies in many major food-producing areas were depleted. The resulting famines eventually killed or debilitated tens of millions of people. The total number of deaths in India and Bangladesh attributed to this bad-weather year was a million or more.

Shortfalls in Soviet, Indian, African, and Peruvian food production led to a 3 percent drop in global grain production in 1972. Such a seemingly small loss, when combined with a growing need for food and a 2 percent annual population growth rate, proved to be a significant problem. Climatologists publicly debated the role of climate in these events and the likelihood that climate-induced troubles would increase.

Grain crises in the mid-1970s. Except for 1974, world grain consumption rose steadily after 1966. Total grain yields began dropping in 1973; they were down by roughly 4.5 percent in 1974 from the 1973 yields. Harvested area was up only about 0.4 percent in 1974 over 1973. Consequently, worldwide grain production in 1974 was set back by about 3 percent—tens of millions of metric tons. In addition, the upward trend in world grain trade broke in 1974. All of this occurred at a time when grain stocks were about the lowest in decades.

Grain security in the 1980s. A number of years of good weather returned to most of the world near the end of the 1970s. However, 1980 was hot and dry in the central United States, which resulted in low yields in summer crops. There were poor harvests in the Soviet Union as well. Consequently, the world had about the same level of grain security—approximately 14 percent—at the beginning of the 1980s as it did entering the 1970s. This level dropped another percentage point the next year, but it recovered somewhat by 1982.

A weather event occurred in 1983 in the United States that illustrates some of the consequences of governmental crop planning and controls. There was a large surplus of grains in 1982 that had farmers complaining about depressed prices for their crops. The U.S. Department of Agriculture introduced a new program that paid grain farmers to withhold acreage from production. It estimated that harvested area in the United States for coarse grains would drop from more than 43,000,000 hectares (106,000,000 acres) in 1982 to an estimated 33,000,000 hectares in 1983. This decrease of 23 percent in crop area by the summer of 1983 occurred at the same time that a heat wave struck the corn belt. Yields of coarse grains

dropped, and production fell to a little under 140,000,000 metric tons, a reduction of nearly half compared to that of 1982. This depleted the existing stocks of coarse grains to about two-thirds by 1984. Fortunately, poor yields did not continue, and there was some recovery the following year. This situation, however, initially had some uncomfortable parallels with that which prevailed just before the food crisis of the early to mid-1970s.

The climatic events of the 1970s and '80s show all too clearly that it is becoming more and more risky to ignore the impact of abnormal weather when making food policy. Climate is not the constant it was assumed to be in past food-policy analyses.

Sahelian drought. The Sahel, which borders the southern fringe of the Sahara in Africa, is extremely prone to drought. Persistent drought conditions, coupled with substantial population growth in the region (an increase of more than 30 percent since the early 1950s) and a doubling of the livestock herd, have resulted in a gradual desertification of the Sahel. Desertification is extremely difficult to reverse. At first, there is a slow loss of soil fertility; this is followed by a process of rapid degradation, with the soil eventually losing its structure and ability to retain enough moisture to sustain vegetation.

Desertification

While climatic variations have played a major role in this disaster, economic and social priorities have been involved as well. The introduction of Western technology made it possible for the inhabitants of the Sahel to drill deep water wells. This situation encouraged the herdsmen not only to give up their nomadic way of life and remain near the wells but also to raise more livestock. Overgrazing resulted and, as drought conditions persisted, competition for forage became more and more intense. Herds of goats tore up the remaining indigenous plants by their roots, thereby destroying the ability of the plants to reproduce by themselves. At the same time, the increasing human population led to the cultivating of more and more marginal, ecologically fragile lands for subsistence farming. (The most fertile lands were frequently used to grow cash crops—namely, cotton and peanuts for foreign markets.) Furthermore, Sahelian farmers began reworking the marginal land within one to five years, whereas they had traditionally allowed these lands to remain fallow for 15 to 20 years, giving them ample time to recover. In changing their farming practices, the Sahelians contributed to the destruction of their lands. As the desert moved southward, so did the people and their livestock. This resulted in further denudation and deforestation. Desertification had set in by the late 1960s, followed by widespread famine. A major international project was undertaken to keep millions of Sahelians alive. Normal rains returned briefly to the Sahel during the mid-1970s; however, since no effective, long-term remedies were applied in animal, agricultural, and human control, outside aid again became necessary in the mid-1980s as drought conditions prevailed once more for a prolonged period (especially in the eastern sections of the sub-Sahara in Ethiopia), causing widespread famine and death. Figure 59 provides an index of rainfall for the Sahel during this period. What caused these droughts is still debated, but one of the theories involves unusual or anomalous temperature patterns in certain parts of the ocean.

From P. Lamb, "Rainfall in Subsaharan West Africa During 1941–83," *Zeitschrift fur Gletscherkunde und Glazialgeologie*, No. 21 (1985)

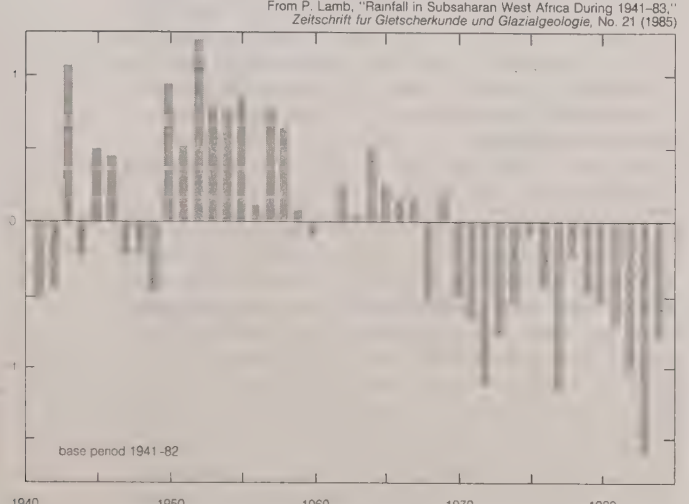

Figure 59: Rainfall index, 1940–83, for 20 sub-Saharan stations in West Africa, west of 10° E between 1° N and 19° N.

El Niño/Southern Oscillation. The interaction between the ocean and the atmosphere also can have a marked impact on life, health, and food. A manifestation of this is the El Niño phenomenon that occurs in the Pacific Ocean. Every few years the temperature of the normally cool surface waters of the eastern equatorial Pacific increases. In turn, the warmer waters affect the atmosphere, and rainfall and surface temperatures along western South America increase substantially. The reduction of cool upwelling water off the western coast disrupts commercial anchovy fishing in the region because the plankton on which the anchovies feed are nourished by nutrients brought up by the colder upwelling water. When the plankton decrease, so do the anchovies.

The El Niño phenomenon is not confined to the waters of South America. The normally warm Pacific water along Australia is replaced by an upwelling of cold water; precipitation in the western Pacific seems to decrease as a result. In addition, changes in atmospheric pressure occur off the shores of Australia, just as they do along the western coast of South America, and wind patterns deviate from their normal course in both cases. Extra-severe drought in Australia and flood-producing torrential rains and heat in South America occur concurrently with and are blamed on El Niño. This entire effect has been referred to as ENSO, for El Niño/Southern Oscillation.

Effect of the ENSO on mid-latitude climates

Studies suggest that the ENSO can affect mid-latitude climates, modulating the position and intensity of the polar-front jet stream (see above). An El Niño event that began in early 1982 lasted well into 1983. It was accompanied by unusual weather events outside of the equatorial Pacific region. Western Europe suffered from record summer heat. Late-fall temperatures in the United States were very cold; winter was mild; spring rains were far above normal and spring temperatures in the central part of the country were extremely cold; and summer conditions in the Midwest and Southeast were extremely hot and dry. These abnormal weather conditions were consistent with a shift in the jet-stream pattern away from its normal one and were with little doubt caused in part by the intense El Niño.

The ENSO appears to be a truly disruptive force that wreaks havoc on life. In 1982–83 it not only caused the drought in Australia and the flooding along the western coast of South America and the loss of the anchovy catch there, but it also damaged corn, soybean, and other summer crops in the United States, which resulted in losses amounting to billions of dollars. Clearly a better understanding of the El Niño and its associated atmospheric effects is needed, leading perhaps to predictive skill.

Impact of human activities on climate

Three distinct atmospheric problems have been debated intensely since about the mid-1970s, though two of them are quite old issues: the possible reduction of stratospheric ozone from chemical emissions; the generation of acid rain; and climatic change stemming from the greenhouse effect. What these three problems have in common is quite simple: they all (1) are complex and punctuated by large uncertainties, (2) could be long-lasting, (3) transcend state and even national boundaries, (4) may be difficult to reverse, (5) are inadvertent by-products of widely supported economic activities, and (6) may require substantial investments of present resources to hedge against the prospect of large future environmental changes.

OZONE DEPLETION

Of these problems, the only one to have received any substantial public policy action is that centring on the reduction of stratospheric ozone. Ironically, it is perhaps the easiest of the problems to reverse.

The importance of the stratospheric ozone layer in shielding the Earth's surface from the harmful effects of solar ultraviolet radiation has been recognized for several decades. It was not until the early 1970s, however, that scientists began actually to grapple with the fact that even relatively small decreases in the stratospheric ozone concentration can have a serious impact on human health—an increased incidence of skin cancer, particularly among fair-skinned peoples. Plans in the United States, Great Britain, and France to build a commercial fleet of supersonic aircraft triggered much heated discussion over the potential reduction of the ozone layer by the exhaust gases (*e.g.*, nitric oxide) emitted by such high-altitude planes. The debate in turn stimulated intensive scientific research on the stratosphere, which resulted in new findings and new concerns.

Efforts to reverse the problem

By the mid-1970s, various U.S. investigators had determined that chlorofluorocarbons (CFCs), widely employed as propellants in aerosol spray cans, could reduce the amount of stratospheric ozone significantly. A temporary ban was imposed on the use of certain CFCs in the United States, but only after much emotional debate among environmental and industrial scientists, reports by the National Academy of Sciences, and the development by industry of economically viable substitutes for spray-can propellants. (For a more detailed discussion of this issue, see ATMOSPHERE: *Depletion of stratospheric ozone.*)

ACID RAIN

Acid precipitation has been known for centuries in locales such as London where sulfur discharged by the burning of coal produces toxic smogs; however, the problem did not assume scientific, economic, and political prominence until the early 1980s. As it transcends national boundaries, the acid rain problem has become a subject of heated controversy between otherwise friendly neighbours like the United States and Canada or Germany and the Scandinavian countries.

Scientific studies have shown that the process that results in the formation of acid rain generally begins with the discharge of sulfur dioxide and nitrogen oxides into the atmosphere. These waste gases are released by the combustion of fossil fuels by automobiles, electric power plants, and smelting and refining facilities. They also are emitted by some biological processes. The gases combine with atmospheric water vapour to form sulfuric and nitric acids. When rain or some other form of precipitation falls to the surface, it is highly acidic, frequently with a pH value of less than 4. (The term pH is defined as the negative logarithm of the hydrogen ion concentration in kilograms per cubic metre. The pH scale ranges from 0 to 14, with lower numbers representing greater acidity.) The consequent acidification of surface and subsurface waters is widely believed to have a detrimental effect on the ecology of the affected areas. Such regions as the Canadian Shield in Quebec and the Adirondack Mountains in New York are especially susceptible to contamination, because the snowpack buildup in winter allows a deadly pulse of acidic meltwater to occur during spring. As highly acidic water is toxic to many aquatic organisms, many lakes in these regions are biologically damaged. It also has been found that acid precipitation is harmful to trees and other forms of vegetation, causing foliar injury and reduction in growth (see also ATMOSPHERE: *Acid rain and allied problems*).

Detrimental effects of acid rain

The "cause-and-effect linkages" of the acid rain problem have been more clearly demonstrated in scientific terms than those related to ozone depletion; yet, the former has received much less direct policy action. The primary reason is the potential economic impact of efforts to remedy the problem—*i.e.*, the enormous expenditure that would be required to control the emission of sulfur compounds from power plants, refineries, and facilities of other smokestack industries. There continues to be loud and angry debate as to the environmental and economic benefits of corrective action, particularly since the relationship between the discharge of potentially acidic compounds and the ultimate delivery of acid precipitation to specific geographic areas is not straightforward.

GREENHOUSE EFFECT INDUCED BY CARBON DIOXIDE AND OTHER TRACE GASES

Finally, the most long-lasting and potentially least reversible global problem is the greenhouse effect. As noted above, this effect is induced by carbon dioxide, chlorofluorocarbons, methane, and more than a dozen other gases in concentration in the atmosphere. The role played by carbon dioxide is the most significant. The amount of CO_2 in the atmosphere has risen steadily since the mid-1800s largely as a result of the combustion of coal, oil, and natural gas on an ever-widening scale. In 1850 the global CO_2 level of the atmosphere was roughly 280 parts per million, whereas by the late 1980s it had increased to approximately 350 parts per million.

The possibility of major climatic changes and their consequences

Should present trends in the emission of greenhouse gases, particularly of CO_2, continue beyond another 100 years, climatic changes larger than any ever experienced during recent geologic periods can be expected. This could substantially alter natural and agricultural ecosystems, human and animal health, and the distribution of climatic resources. In addition, any significant greenhouse warming could cause a rapid melting of some polar ice, resulting in a rise in sea level and the consequent flooding of coastal areas.

In spite of these long-term possibilities, the greenhouse problem has received the least policy-oriented attention of any of the three major issues at hand. There are various reasons for this: (1) The problem is fraught with technical uncertainties. (2) It has perceived "winners" and "losers"—economic and otherwise. (3) No one nation acting alone can do much to counteract the CO_2 buildup in the atmosphere. (4) Dealing with the problem substantively could be expensive and even alter life-styles. (5) There is no way of proving the validity of the greenhouse theory to everyone's satisfaction except by "performing the experiment" on the real climatic system, which would necessarily involve all living things on Earth. (6) The principal greenhouse gas, CO_2, is an inherent by-product of the utilization of a commodity that is most fundamental to the economic viability of the world—fossil-fuel energy. (This fact more than any other explains why the greenhouse problem is so difficult to solve.)

Detailed analysis of the problem. It seems appropriate to break down the issue of greenhouse warming into a series of stages and then consider how policy questions might be addressed against the background of these more technical stages. The present discussion will deal with the problem specifically as it relates to increasing atmospheric CO_2 for the sake of simplicity, though other related questions certainly can be dealt with in the same manner.

Behavioral assumptions. At the very basis of the problem is the need to make behavioral assumptions about the future use of fossil fuels (or alternatively of the projected extent of deforestation, because this, too, can affect the amount of carbon dioxide in the atmosphere; see above). In essence, this issue has to do with social science rather than with chemistry, physics, or biology. It depends on projections of human population, the per-capita consumption of fossil fuel, deforestation rates, reforestation activities, and perhaps even countermeasures for dealing with the additional CO_2. These projections, of course, are contingent on such questions as the likelihood of alternative energy systems or conservation measures becoming available, their costs, and their acceptability to society. Furthermore, trade in carbon-based fuels will be determined not only by energy requirements and available alternatives but also by the economic health of potential importing nations. This, in turn, will depend on whether those nations have adequate capital resources to spend on energy, rather than on other precious strategic commodities such as food or fertilizer or even weaponry. The future can be projected by drawing up scenarios such as that in Figure 60, which shows different projected CO_2 concentrations based on assumed rates of growth in the use of fossil fuels. Most typical projections are in the 1–2 percent annual growth range, implying doubling of atmospheric CO_2 by the middle of the 21st century. It has already increased by some 25 percent in the 20th century.

Carbon cycle. Once the plausible scenarios for CO_2

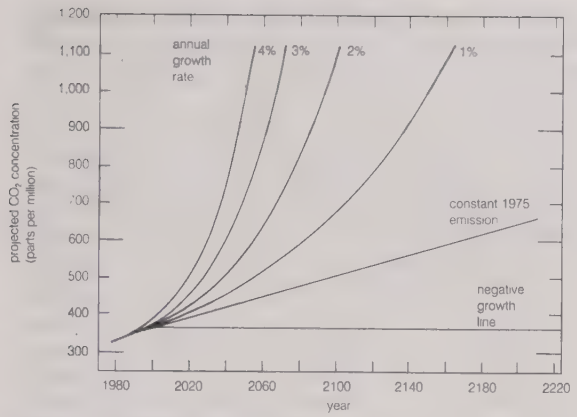

Figure 60: *Projected carbon dioxide concentrations from 1980 for different annual growth rates in fossil-fuel energy use.* The projections reflect the assumption that no increase in fossil-fuel energy use will occur (constant 1975 emission) and the possibility of negative growth, with annual energy growth after 1985 assumed to be reduced by a fixed amount (about 2 percent of present demand) each year.

From (data for negative growth line) A.B. Lovins *et al*., *Least-Cost Energy: Solving the CO_2 Problem* (1982), Brick House, (remaining data) S.H. Schneider and R. Londer, *The Coevolution of Climate and Life*, copyright ©1984 by S.H. Schneider and R. Londer, reprinted with permission of Sierra Club Books

buildup have been devised, it is necessary to determine exactly which interacting biogeochemical processes control the global distribution of carbon and its stocks. This involves uptake by green plants (since CO_2 is the basis of photosynthesis, more CO_2 in the air means faster rates of photosynthesis), changes in the amount of forested area, the types of vegetation planted, and the way in which climatic change affects natural ecosystems. The growth rate of photosynthesizers, such as grain plants and trees, may well increase. On the other hand, weeds and vegetation that harbour disease-bearing insects would also become more vigorous. Moreover, since there is a slow removal of CO_2 from the atmosphere, largely accomplished through chemical processes in the ocean that take from decades to centuries, the rates at which climatic change modifies mixing processes in the ocean also need to be taken into account. There is considerable uncertainty over just how much CO_2 will remain in the air, but most present estimates put the so-called airborne fraction at about 50 percent, which suggests that, over the time frame of a century or two at least, something like half the CO_2 injected into the atmosphere will remain and exacerbate the greenhouse effect.

Global climatic response. Once the amount of carbon dioxide that may exist in the atmosphere over the next century or so has been projected, its significance in terms of climate has to be estimated. The greenhouse effect, notwithstanding all of the controversy that surrounds the term, is not a scientifically controversial subject. In fact, it is one of the best, most well-established theories in the atmospheric sciences. For example, with its extremely dense atmosphere composed largely of CO_2, Venus has very high surface temperatures (up to about 500° C). By contrast, Mars, with its very thin CO_2 atmosphere, has temperatures comparable to those that prevail at the Earth's poles in winter. The explanation for the Venus hothouse and the Martian deep freeze is really quite clear—the greenhouse effect. This mechanism works because some gases and particles in a planet's atmosphere preferentially allow sunlight to filter through to the surface of the planet relative to the amount of radiant energy that the atmosphere allows to escape back to space. This latter kind of energy (infrared energy) is affected by the amount of greenhouse material in the atmosphere. Therefore, increasing the amount of greenhouse gases raises the surface temperature of the planet by increasing the amount of heat that is trapped in the lowest part of its atmosphere. While that part of the subject is not controversial, what is open to debate is exactly how much the Earth's surface temperature will rise given a certain increase in a trace greenhouse gas such as CO_2. Complications arise due to processes known as feedback mechanisms. For example, if the CO_2 added to the atmosphere were to cause a given temperature increase on Earth, warming would melt some of the snow and ice that now exist. Thus, the white surface, originally covered by the melted snow and ice, would be replaced with darker blue ocean or brown soil, surface conditions that would absorb more sunlight than the snow and ice. Consequently, the initial warming would create a darker planet that absorbs more solar energy and thereby produces greater warming in the end. This is only one of a number of possible feedback mechanisms, however. Because many of them are interacting simultaneously in the climatic system, it is extremely difficult to estimate quantitatively how many degrees of warming the climate will undergo for any given increase in greenhouse trace gases.

The effect of feedback mechanisms

Unfortunately, there is no period in Earth history that investigators can examine when carbon dioxide concentrations in the atmosphere were, say, twice what they are today and whose climatic conditions are known with a high degree of certainty. For this reason, investigators cannot directly verify their quantitative predictions of greenhouse warming on the basis of historical analogs. Instead, they must base their estimates on climatic models. These are not laboratory models, since no laboratory could approach the complexity of the real world. Rather, they are mathematical models in which basic physical laws are applied to the atmosphere, ocean, and glaciers; the equations representing these laws are solved with computers with the aim of simulating the present terrestrial climate.

Estimates of greenhouse warming based on climatic models

Many such models have been built during the past few decades. The calculations roughly agree that, if the atmospheric CO_2 concentrations were to double, the Earth's surface temperature would warm up somewhere between 1° and 5° C. As a point of comparison, the global surface temperature of the Earth during the Ice Age 18,000 years ago was on average about 5° C lower than it is today. Thus, a temperature change of more than one or two degrees worldwide represents a very substantial alteration.

Regional climatic response. To estimate the importance of climatic changes to society, researchers need not, however, study global average temperature so much as the possible regional distribution of evolving patterns of climatic change in the future. Will it, in the year 2010, be drier in Iowa, wetter in Africa, more humid in New York, or too hot in India? Unfortunately, to predict reliably the fine-scale regional response of variables, such as temperature and rainfall, requires climatic models of greater complexity (and cost) than are currently available. At present, there is simply no consensus among knowledgeable atmospheric scientists that the regional predictions of state-of-the-art models are reliable. Nevertheless, most experts agree that the following coherent regional features might well occur by about the year 2035: wetter subtropical monsoonal rain belts; longer growing seasons in high latitudes; wetter springs in high and middle latitudes; drier midsummer conditions in some mid-latitude areas (a potentially serious agricultural and water supply problem in major grain-producing nations); increased probability of extreme heat waves (with possible health consequences for people and animals in already warm climates); and an increase in sea level by a few tens of centimetres. Considerable uncertainty remains in these regional estimates, even though many plausible scenarios have been investigated.

Projected climatic variations resulting from greenhouse warming

Environmental impact. The possible impact on environment and society needs to be determined from a given set of scenarios for regional climatic change. Most important are the effects on crop yields and water supply. Also of concern is the potential for altering the range or number of pests that affect plants and diseases that threaten the health of humans or lower animal forms. Another point of interest is the effect on unmanaged ecosystems. For example, ecologists are much concerned that the rapid rate at which tropical forests are being destroyed due to human expansion is eroding the genetic diversity of the Earth. Since the tropical forests are in a sense repositories for the bulk of living genetic materials on Earth, the world is losing some of its irreplaceable biologic resources. In addition, substantial future changes to tropical rainfall have been predicted by climatic models. This means that present-day reserves (or refugia) may be unable to sustain

those species that they are designed to protect if rapidly evolving climatic change produces conditions in the refugia sufficiently different from those of today.

Economic, social, and political effects. Estimating the distribution of economic winners and losers, given a scenario of climatic change, involves more than simply looking at the total dollars lost and gained, were it possible to make credible calculations. It also requires looking at such important equity questions as who wins and who loses and how the losers might be compensated and the winners taxed. If the corn belt in the United States, for example, were to "move" north by several hundred kilometres as a result of greenhouse warming, then $1,000,000,000 a year lost on Iowa farms could well become Minnesota's $1,000,000,000 gain. Some macroeconomic views of this hypothetical problem, from the perspective of the United States as a whole, might see no net losses. Much social consternation, however, would be generated by such a shift in climate, particularly since the cause of the change would be economic, CO_2-producing activities. Even the perception that the economic activities of one nation could create climatic changes that would be detrimental to another has the potential for disrupting international relations, as is already occurring in the case of acid rain. While the details are still difficult to establish, there is considerable scientific consensus that regional climatic changes of environmental significance are likely to occur over the next few generations. In essence, the environmental changes induced by CO_2 and other greenhouse gases create what might be termed a problem of "redistributive justice."

Policy responses. The last stage in dealing with the greenhouse effect concerns the matter of appropriate policy responses. Three classes of action could be considered.

Possible ways of dealing with the greenhouse effect

The first is mitigation through purposeful intervention to minimize the potential effects on the environment. For example, dust might be deliberately spread in the stratosphere to reflect some sunlight and cool the climate as a countermeasure to inadvertent warming by a CO_2 buildup. This solution suffers from the obvious flaw that, since there is uncertainty associated with predicting the inadvertent consequences of human activities, substantial uncertainty must surround any deliberate attempts at climatic modification. It may be that existing computer models overestimate changes and underestimate proposed modification schemes. If so, human intervention would be the proverbial "cure worse than the disease." In that case, the prospect for international tensions is so staggering and society's legal instruments to deal with the problem so immature that it is hard to imagine any substantial mitigation strategies for the foreseeable future.

The second is simply adaptation. Adaptive strategies, favoured by many economists, would simply allow society to adjust to environmental changes without attempting to mitigate or prevent the changes in advance. It would be possible to accommodate climate change, for instance, by planting alternative crop strains that would be more widely adapted to a whole range of plausible climatic conditions anticipated for the future. Such adaptive strategies are often recommended because of the uncertain nature of the redistributive character of future climatic change.

The third type of policy response, namely prevention, is the most active. It might involve discontinuing the use of chlorofluorocarbons and other potential ozone-reducing gases, or a reduction in the amount of fossil fuel used around the world. These policies, often advocated by environmentalists, are controversial because in some cases they require substantial immediate investment as a hedge against large future environmental change, change that cannot be predicted precisely. What can be considered practical options are increasing the efficiency of energy end use (in a word, conservation), the development of alternative energy systems that are not based on fossil fuels, or, more radically, establishing a "law of the air." Such a measure was proposed in 1976 by two American scientists, the anthropologist Margaret Mead and the climatologist William W. Kellogg. To curtail CO_2 emissions, they suggested setting up a global standard and assigning various nations the right to generate certain levels of the gas.

The "appropriate" policy response will depend not only on scientific information about the probabilities and consequences of physical, biologic, and social impact scenarios but also on the value judgments of individuals, groups, corporations, and nations as to how to deal with the potential distribution of gains and losses implied by the buildup of carbon dioxide and other trace gases. There is no scientific answer as to how society should act and no scientific basis for any particular policy choice. All science can do is provide scenarios and assess the probabilities and consequences of various plausible alternatives. The public and government leaders need to understand that decisions have to be made in the face of scientific uncertainty by optimizing clearly stated sets of often conflicting values.

Atmospheric problems are fundamentally global in both cause and effect. Moreover, they are inextricably interwoven with the overall problem of global economic development and cannot be removed from the discussion of population, resources, environment, and economic justice. Rich nations cannot ask poor nations to abandon their development plans simply because of the potential CO_2 problem. Any global strategies for preventing CO_2 buildup will require cooperation between rich and poor nations on the transfer of knowledge, technology, and capital.

A further point of contention in the dialogue between developed and developing countries will be the question of population-growth rates. This is quite relevant to the CO_2 issue simply because total emission is the per-capita emission rate times the population size. If there is a movement in the future toward parity between rich and poor in per-capita use of fossil fuels, then population growth (which is occurring predominantly in Third World countries) will become as important a factor in the long-term CO_2/climate problem as is high per-capita use of fossil fuels today (largely a problem of developed nations).

Furthermore, there is an ethical question associated with atmospheric problems: Do we have the right to commit future generations to unprecedented atmospheric perturbations without actively attempting to prevent or at least anticipate them? To be sure, there is much uncertainty. It is safe to say, however, that humankind is abusing the atmospheric environment faster than it is understanding it. Clearly, some of the uncertain consequences could be serious and even irreversible.

From S. Manabe and R.J. Stouffer, *Journal of Geophysical Research*, 85 5529–54 (1980), published by the American Geophysical Union

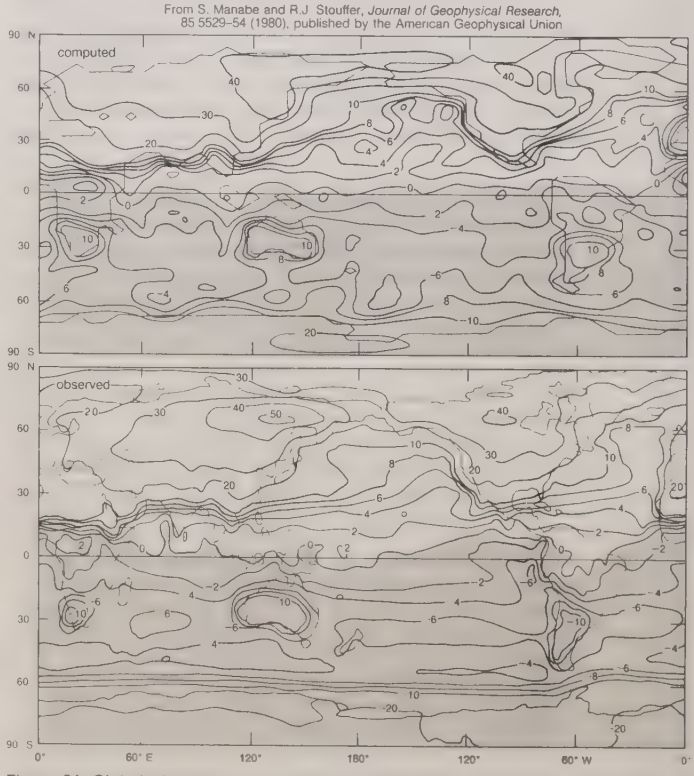

Figure 61: Global winter-to-summer temperature extremes, computed (top) and observed (bottom). A three-dimensional climate model was used for the top map.

Verification of model predictions. The largest climatic change to occur on Earth since the dinosaurs inhabited the planet some 100,000,000 years ago is the seasons. Temperature differences between winter and summer are many tens of degrees—in some cases 10 times—larger than those anticipated over the next century from an intensification of the greenhouse effect. How well, then, do existing climatic models fare in predicting this massively large seasonal change? They do quite well, in fact, as Figure 61 suggests. Thus, it is not likely that climatic models are making a fundamental error in predicting future warming and at the same time reproducing the very large seasonal differences that they do. On the other hand, seasonal variations occur within a year, whereas the rate of change for an increase of trace gases in the atmosphere is many decades. In effect, seasonal simulation skill is a piece of circumstantial evidence and not final proof of model validity. Nevertheless, it certainly lends a great deal of credence to the basic theoretical claims behind the greenhouse effect.

Comparisons with Venus and Mars

What other bits of supporting evidence can be brought to bear? The furnacelike conditions on Venus and the frigid air of Mars were noted above. When data on the atmospheric composition of these planets are fed to the computer models used to predict greenhouse warming on the Earth, corresponding changes are indeed produced—*i.e.,* temperatures on Venus are hundreds of degrees warmer and those of Mars are hundreds of degrees colder. Is this proof that the mathematical models are accurately predicting the terrestrial greenhouse effect? Again, the evidence is only circumstantial but strong. One other piece of circumstantial evidence can be cited—namely, the ability of present climatic models to reproduce the vastly different conditions on Earth during ancient times when ice stretched all the way from the Arctic to northern Europe and the mid-Atlantic region of the United States.

Finally, what has been happening to the Earth's climate during the past 100 years? If one takes all of the reliable records of temperature readings and averages them for the world, one finds that the Earth has warmed up about 0.5° C over the past century. At the same time, it has been determined that the CO_2 level is about 25 percent higher today than it was a century ago. Therefore, what has happened on Earth is broadly consistent with what the climatic models suggest should have been happening. The warming of the planet over the past century is yet another piece of circumstantial evidence, not conclusive proof in and of itself, but still important. (S.H.S./A.B.Ri.)

METEOROLOGICAL MEASUREMENT AND WEATHER FORECASTING

General considerations

MEASUREMENTS AND IDEAS AS THE BASIS FOR WEATHER PREDICTION

The link between meteorological measurement and weather forecasting, the two topics of this section, is both necessary and convenient: necessary because all weather forecasts are grounded in data that have only very recently been measured, and convenient because attention is focused on the central importance of observations for the practice of science. With few other scientific enterprises are observations so vital as in the case of weather forecasting. From the days when early humans ventured from caves and other natural shelters, perceptive individuals in all likelihood became leaders by being able to detect nature's signs of impending snow, rain, or wind, indeed of any change in weather. With such information they must have enjoyed greater success in the search for food and safety, the major objectives of that time.

In a sense, weather forecasting is still carried out in basically the same way as it was by the earliest humans—namely, by making observations and predicting changes. The tools used to measure temperature, pressure, wind, and humidity in the late 20th century would certainly amaze them, and the results obviously are better. Yet, even the most sophisticated numerically calculated forecast made on a supercomputer requires a set of measurements of the condition of the atmosphere—an initial picture of temperature, wind, and other basic elements, somewhat comparable to that formed by our forebears when they looked out of their cave dwellings. The primeval approach entailed insights based on the accumulated experience of the perceptive observer, while the modern technique consists of solving equations. Although seemingly quite different, there are underlying similarities between both practices. In each case the forecaster asks "What is?" in the sense of "What kind of weather prevails today?" and then seeks to determine how it will change in order to extrapolate what it will be.

Because observations are so critical to weather prediction, an account of meteorological measurements and weather forecasting is a story in which ideas and technology are closely intertwined, with creative thinkers drawing new insights from available observations and pointing to the need for new or better measurements, and technology providing the means for making new observations and for processing the data derived from measurements. It tells of the theories of the ancient Greek philosophers, Renaissance scientists, and the scientific revolution of the 17th and 18th centuries and of the creativity of 20th-century atmospheric scientists and meteorologists. Likewise, it tells of the development of the "synoptic" idea—that of characterizing the weather over a large region at exactly the same time in order to organize information about prevailing conditions. In synoptic meteorology, simultaneous observations for a specific time are plotted on a map for a broad area whereby a general view of the weather in that region is gained. (The term synoptic is derived from the Greek word meaning "general or comprehensive view.") The so-called synoptic weather map came to be the principal tool of 19th-century meteorologists and continues to be used today in weather stations and on television weather reports around the world.

The synoptic approach

Figure 62 provides an example of an early synoptic map, which depicts the conditions on the morning of March 13, 1888, during the famous blizzard that paralyzed New York City for days and caused about 400 deaths. The storm delivered 60 to 120 centimetres of blowing, drifting snow, amid very cold temperatures, to a wide area from western New England to New Jersey on the heels of mild springlike weather. The map shows that the storm centre, where the sea-level pressure is lowest, was off the eastern tip of Long Island on the morning of the 13th, with a new centre forming far out at sea. Lines of equal pressure (isobars) circle the storm, as do the winds. The crowded isobars around the very low pressure at the centre imply strong winds. The dashed lines of equal temperature (isotherms) show that the storm occurred in connection with a great outbreak of subzero (in Fahrenheit) air from the continental interior, which was carried far into the Atlantic by the storm circulation. Tracing the 60° and 50° isotherms in the Atlantic shows that it was 55° F that morning in Bermuda, a rare event even at that distance from the storm.

Synoptic maps of this sort created a comprehensive picture. The synoptic meteorologist became an expert at drawing weather maps and interpreting prevailing conditions to be able to infer future conditions.

Since the mid-20th century, digital computers have made it possible to calculate changes in atmospheric conditions mathematically and objectively—*i.e.,* in such a way that anyone can obtain the same result from the same initial conditions. The widespread adoption of numerical weather prediction models brought a whole new group of players—computer specialists and experts in numerical processing and statistics—to the scene to work with

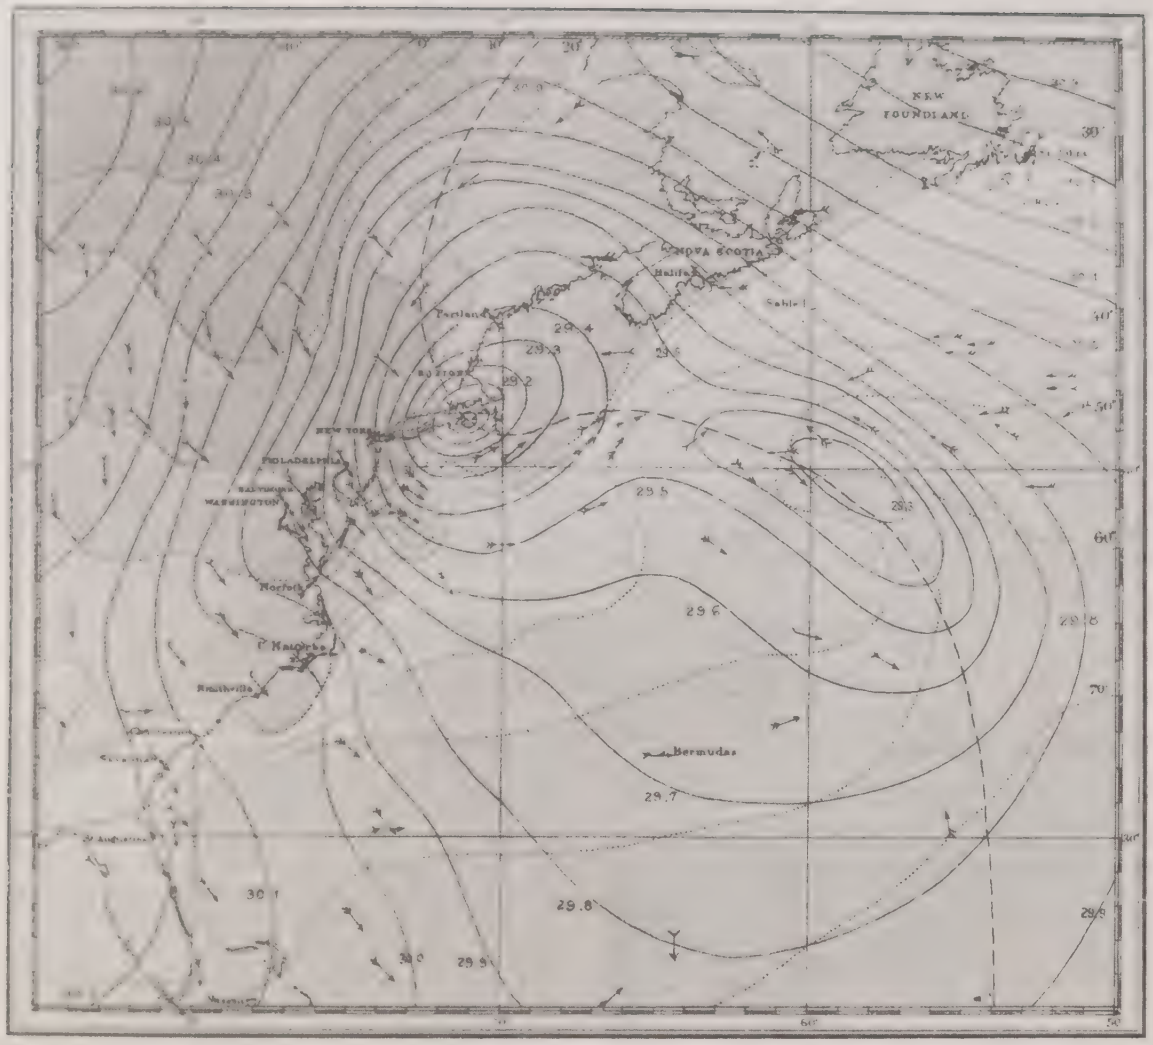

Figure 62: Surface weather map showing the meteorological conditions at 7:00 AM, EST, on March 13, 1888, during the great storm of March 11–14; from the first issue of *National Geographic Magazine*, October 1888 (see text).

atmospheric scientists and meteorologists. Moreover, the enhanced capability to process and analyze weather data stimulated the long-standing interest of meteorologists in securing more observations of greater accuracy. Technological advances since the 1960s have led to a growing reliance on remote sensing, particularly the gathering of data with specially instrumented Earth-orbiting satellites. By the late 1980s, forecasts of weather were largely based on the determinations of numerical models integrated by high-speed supercomputers, except some shorter-range predictions, particularly of local weather conditions, which were made by specialists directly interpreting radar and satellite measurements.

PRACTICAL APPLICATIONS OF WEATHER FORECASTING

Systematic weather records were kept after instruments for measuring atmospheric conditions became available during the 17th century. Undoubtedly these early records were employed mainly by those engaged in agriculture. Planting and harvesting obviously can be planned better and carried out more efficiently if long-term weather patterns can be estimated. In the United States, national weather services were first provided by the Army Signal Corps beginning in 1870. These operations were taken over by the Department of Agriculture in 1891. By the early 1900s free mail service and telephone were providing forecasts daily to millions of American farmers. The U.S. Weather Bureau established a Fruit-Frost (forecasting) Service during World War I, and by the 1920s radio broadcasts to agricultural interests were being made in most states.

Weather forecasting became an important tool for aviation during the 1920s and '30s. Its application in this area gained in importance after Francis W. Reichelderfer was appointed chief of the U.S. Weather Bureau in 1939. Reichelderfer had previously modernized the navy's meteorological service and made it a model of support for naval aviation. During World War II the discovery of very strong wind currents at high altitudes (the jet streams, which can affect aircraft speed) and the general susceptibility of military operations in Europe to weather led to a special interest in weather forecasting.

The most famous wartime forecasting problem was for Operation Overlord, the invasion of the European mainland at Normandy by Allied forces. An unusually intense June storm brought high seas and gales to the French coast, but a moderation of the weather that was successfully predicted by Colonel J.M. Stagg of the British forces (after consultation with both British and American forecasters) enabled General Dwight D. Eisenhower, supreme commander of the Allied Expeditionary Forces, to make his critical decision to invade on June 6, 1944.

Importance of commercial weather-forecasting organizations

The second half of the 20th century has seen unprecedented growth of commercial weather-forecasting firms in the United States and elsewhere. Marketing organizations and stores commonly hire weather-forecasting consultants to help with the timing of sales and promotions of products ranging from snow tires and roofing materials to summer clothes and resort vacations. Many oceangoing shipping vessels as well as military ships use optimum ship routing forecasts to plan their routes in order to minimize lost time, potential damage, and fuel consumption

in heavy seas. Similarly, airlines carefully consider atmospheric conditions when planning long-distance flights so as to avoid the strongest head winds and to ride with the strongest tail winds.

International trading of foodstuffs such as wheat, corn (maize), beans, sugar, cocoa, and coffee can be severely affected by weather news. For example, in 1975 a severe freeze in Brazil caused the price of coffee to increase substantially within just a few weeks, and in 1977 a freeze in Florida nearly doubled the price of frozen concentrated orange juice in a matter of days. Weather-forecasting organizations are thus frequently called upon by banks, commodity traders, and food companies to give them advance knowledge of the possibility of such sudden changes.

The cost of all sorts of commodities and services, whether they are tents for outdoor events or plastic covers for the daily newspapers, can be reduced or eliminated if reliable information about possible precipitation can be obtained in advance.

Forecasts must be quite precise for applications that are tailored to specific industries. Gas and electric utilities, for example, may require forecasts of temperature within one or two degrees of the mean a day ahead of time, or ski-resort operators may need prior estimates of nighttime relative humidity on the slopes within 5 to 10 percent in order to schedule snow making.

History of weather forecasting

EARLY MEASUREMENTS AND IDEAS

The Greek philosophers had much to say about meteorology, and many who subsequently engaged in weather forecasting no doubt made use of their ideas. Unfortunately, they probably made many bad forecasts, because Aristotle, who was the most influential, did not believe that wind is air in motion. He did believe, however, that west winds are cold because they blow from the sunset.

The scientific study of meteorology did not develop until measuring instruments became available. Its beginning is commonly associated with the invention of the mercury barometer by Evangelista Torricelli, an Italian physicist-mathematician, in the mid-17th century and the nearly concurrent development of a reliable thermometer. (Galileo had constructed an elementary form of gas thermometer in 1607, but it was defective; the efforts of many others finally resulted in a reasonably accurate liquid-in-glass device.)

Key inventions and discoveries

A succession of notable achievements by chemists and physicists of the 17th and 18th centuries contributed significantly to meteorological research. The formulation of the laws of gas pressure, temperature, and density by Robert Boyle and Jacques-Alexandre-César Charles, the development of calculus by Isaac Newton and Gottfried Wilhelm Leibniz, the development of the law of partial pressures of mixed gases by John Dalton, and the formulation of the doctrine of latent heat (*i.e.*, heat release by condensation or freezing) by Joseph Black are just a few of the major scientific breakthroughs of the period that made it possible to measure and better understand theretofore unknown aspects of the atmosphere and its behaviour. During the 19th century, all of these brilliant ideas began to produce results in terms of useful weather forecasts.

THE EMERGENCE OF SYNOPTIC FORECASTING METHODS

Analysis of synoptic weather reports. An observant person who has learned nature's signs can interpret the appearance of the sky, the wind, and other local effects and "foretell the weather." A scientist can use instruments at one location to do so even more effectively. The modern approach to weather forecasting, however, can only be realized when many such observations are exchanged quickly by experts at various weather stations and entered on a synoptic weather map to depict the patterns of pressure, wind, temperature, clouds, and precipitation at a specific time. Such a rapid exchange of weather data became feasible with the development of the electric telegraph in 1837 by Samuel F.B. Morse of the United States. By 1849 Joseph Henry of the Smithsonian Institution in Washington, D.C., was plotting daily weather maps based on telegraphic reports, and in 1869 Cleveland Abbe at the Cincinnati Observatory began to provide regular weather forecasts using data received telegraphically.

Importance of the telegraph

Synoptic weather maps resolved one of the great controversies of meteorology—namely, the rotary storm dispute. By the early decades of the 19th century, it was known that storms were associated with low barometric readings, but the relation of the winds to low-pressure systems, called cyclones, remained unrecognized. William Redfield, a self-taught meteorologist from Middletown, Conn., noticed the pattern of fallen trees after a New England hurricane and suggested in 1831 that the wind flow was a rotary counterclockwise circulation around the centre of lowest pressure. The American meteorologist James P. Espy subsequently proposed in his *Philosophy of Storms* (1841) that air would flow toward the regions of lowest pressure and then would be forced upward, causing clouds and precipitation. Both Redfield and Espy proved to be right (see Figure 62). The air does spin around the cyclone, as Redfield believed, while the layers close to the ground flow inward and upward as well. The net result is a rotational wind circulation that is slightly modified at the Earth's surface to produce inflow toward the storm centre, just as Espy had proposed. Further, the inflow is associated with clouds and precipitation in regions of low pressure, though that is not the only cause of clouds there.

In Europe the writings of Heinrich Dove, a Polish scientist who directed the Prussian Meteorological Institute, greatly influenced views concerning wind behaviour in storms. Unlike the Americans, Dove did not focus on the pattern of the winds around the storm but rather on how the wind should change at one place as a storm passed. It was many years before his followers understood the complexity of the possible changes.

Establishment of weather-station networks and services. Routine production of synoptic weather maps became possible after networks of stations were organized to take measurements and report them to some type of central observatory. As early as 1814, U.S. Army Medical Corps personnel were ordered to record weather data at their posts; this activity was subsequently expanded and made more systematic. Actual weather-station networks were established in the United States by New York University, the Franklin Institute, and the Smithsonian Institution during the early decades of the 19th century.

In Britain, James Glaisher organized a similar network, as did Christophorus H.D. Buys Ballot in The Netherlands. Other such networks of weather stations were developed near Vienna, Paris, and St. Petersburg.

It was not long before national meteorological services were established on the Continent and in the United Kingdom. The first national weather service in the United States commenced operations in 1871, with responsibility assigned to the U.S. Army Signal Corps. The original purpose of the service was to provide storm warnings for the Atlantic and Gulf coasts and for the Great Lakes. Within the next few decades, national meteorological services were established in such countries as Japan, India, and Brazil. The importance of international cooperation in weather prognostication was recognized by the directors of such national services. By 1880 they had formed the International Meteorological Organization (IMO) for this end.

Establishment of national meteorological services

The proliferation of weather-station networks linked by telegraphy made synoptic forecasting a reality by the close of the 19th century. Yet, the daily weather forecasts generated left much to be desired. Many errors occurred as predictions were largely based on the experience that each individual forecaster had accumulated over several years of practice, vaguely formulated rules of thumb (*e.g.*, of how pressure systems move from one region to another), and associations that were poorly understood, if at all.

PROGRESS DURING THE EARLY 20TH CENTURY

An important aspect of weather prediction is to calculate the atmospheric pressure pattern—the positions of the highs and lows and their changes. Modern research has shown that sea-level pressure patterns respond to the motions of the upper-atmospheric winds, with their narrow, fast-moving jet streams and remarkable waves that flow

through the air and pass air through themselves (see above *Upper-air waves*).

Early attempts to study the upper atmosphere

Frequent surprises and errors in estimating surface atmospheric pressure patterns undoubtedly caused 19th-century forecasters to seek information about the upper atmosphere for possible explanations. The British meteorologist Glaisher made a series of ascents by balloon during the 1860s, reaching an unprecedented height of nine kilometres. At about this time investigators on the Continent began using unmanned balloons to carry recording barographs, thermographs, and hygrographs to high altitudes. During the late 1890s meteorologists in both the United States and Europe used kites equipped with instruments to probe the atmosphere up to altitudes of about three kilometres. Notwithstanding these efforts, knowledge about the upper atmosphere remained very limited at the turn of the century. The situation was aggravated by the confusion created by observations from weather stations located on mountains or hilltops. Such observations often did not show what was expected, partly because so little was known about the upper atmosphere and partly because the mountains themselves affect measurements, producing results that are not representative of what would be found in the free atmosphere at the same altitude.

Fortunately, a large enough number of scientists had already put forth ideas that would make it possible for weather forecasters to think three-dimensionally, even if sufficient meteorological measurements were lacking. Henrik Mohn, the first of a long line of highly creative Norwegian meteorologists, Wladimir Köppen, the noted German climatologist (see above), and Max Margules, an influential Russian-born meteorologist, all contributed to the view that mechanisms of the upper air generate the energy of storms.

In 1911 William H. Dines, a British meteorologist, published data that showed how the upper atmosphere compensates for the fact that the low-level winds carry air toward low-pressure centres. Dines recognized that the inflow near the ground is more or less balanced by a circulation upward and outward aloft. Indeed, for a cyclone to intensify, which would require a lowering of central pressure, the outflow must exceed the inflow; the surface winds can converge quite strongly toward the cyclone, but sufficient outflow aloft can produce falling pressure at the centre.

Meteorologists of the time were now aware that vertical circulations and upper-air phenomena were important, but they still had not determined how such knowledge could improve weather forecasting. Then, in 1919, the Norwegian meteorologist Jacob Bjerknes introduced what has been referred to as the Norwegian cyclone model. This theory (depicted in Figure 63) pulled together many earlier ideas and related the patterns of wind and weather to a low-pressure system that exhibited fronts—rather sharp sloping boundaries between cold and warm air masses. Bjerknes pointed out the rainfall/snowfall patterns that are characteristically associated with the fronts in cyclones: the rain or snow occurs over large areas on the cold side of an advancing warm front ahead of advancing low pressure. Here, the winds are from the south and the warm air, being light, glides up over a large region of cold air. Widespread, sloping clouds spread ahead of the cyclone; barometers fall as the storm approaches, and precipitation from the rising warm air falls through the cold air below. Where the cold air advances to the rear of the storm, squalls and showers mark the abrupt lifting of the warm air being displaced. Thus, the concept of fronts focused attention on the action at air mass boundaries. The Norwegian cyclone model could be called the frontal model, for the idea of warm air masses being lifted over cold air along their edges (fronts) became a major forecasting tool. The model not only emphasized the idea but it also showed how and where to apply it.

In later work, Bjerknes and several other members of the so-called Bergen school of meteorology expanded the model to show that cyclones grow from weak disturbances on fronts, pass through a regular life cycle, and ultimately die by the inflow filling them (see above *Extratropical cyclones* and Figure 22). Both the Norwegian cyclone model and the associated life-cycle concept are still used today by weather forecasters.

While Bjerknes and his Bergen colleagues refined the cyclone model, other Scandinavian meteorologists provided much of the theoretical basis for modern weather prediction. Foremost among them were Vilhelm Bjerknes, Jacob's father, and Carl-Gustaf Rossby. Their ideas helped make it possible to understand and carefully calculate the changes in atmospheric circulation and the motion of the upper-air waves that control the behaviour of cyclones.
